The freshly prepared chlorinated jute, when immersed in a solution of sodium sulphite, develops a magnificent magenta colour, which has been of great value in the study of the constitution of this body and in the diagnosis of plant substances generally. By its means we have been able to demonstrate the very wide distribution in the plant world of substances allied to lignose. One rather striking example may be cited. If a thin section of a pear be exposed to the action of chlorine for some time and then treated with sodium sulphite solution, this coloration is produced in spots more or less regularly disposed in the flesh, showing very clearly the arrangement of the so-called stony concretions.

This magenta reaction is much more delicate, and, therefore, more reliable than the well-known one with aniline sulphate. It has been shown by Dr. Hugo Müller, that the latter reaction is not due to lignose itself, but to a body which always accompanies it, present in very small quantities. In confirmation of this we have found that if jute be boiled for a short time in a solution of sodium sulphite, this body is either removed or so altered that the fibre no longer gives the yellow coloration, but still possesses the power of giving the magenta reaction after chlorination. Therefore, lignose can be regarded quite apart from the aniline sulphate reaction.* We have found, moreover, that the reaction is given in a more or less striking degree by many aldehydes, such for example as vanillin and cinnamic aldehyde. If the latter be shaken up with a strong solution of aniline sulphate it presently solidifies to a mass of deep yellow crystals. At the time we were investigating the chlorine derivative from jute, we were led to examine the liquors obtained in the process of manufacturing paper pulp from esparto by boiling it in caustic soda solution. If these liquors be acidified with HCl and the resulting precipitate of resin be treated with $KClO_3$ and HCl, a bright yellow chlorinated derivative is obtained, which after purification yields on combustion numbers pointing to the formula $C_{22}H_{23}Cl_4O_{10}$, and which in most of its properties resembles that obtained from jute.

These bodies are very slightly soluble in water but freely so in a solution of sodium sulphite, and if these solutions be examined they will be found to be somewhat astringent to the taste and to possess the property of precipitating solutions of gelatin. If, moreover, freshly chlorinated jute or sections of pear be treated with a solution of ferric chloride after previous treatment with sodium sulphite, a distinct green coloration may be observed.

All these observations point to a relation of the original substances to the tannins. The original substances, however, do not give any such reactions, or only the very faintest, and these facts together with a consideration of certain theories as to the origin of tannins, led us to speak of the non-cellulose portion of jute and similar bodies as "potential tannins." Moreover, if tannin itself be exposed to chlorine, it is rapidly converted into an orange-coloured derivative, which gives with sodium sulphite the magenta reaction previously described.

This view of the constitution of the jute substance, which, as we have seen, was an amplification of our former views, has itself been extended by subsequent investigation. The well-known relations existing between tannin, gallic acid and pyrogallol, led us to examine the action of chlorine on the latter body. This work had already been done by Stenhouse and Groves, who found that by treating pyrogallol dissolved in glacial acetic acid with a current of dry chlorine, certain precautions being taken, it was converted into a mixture of bodies, the greater part of which were amorphous and very difficult to manipulate. They were able, however, to isolate a body in the form of brilliant crystals, to which they gave the name of mairogallol. We found that both mairogallol and the amorphous bodies that accompany it give the magenta reaction with great brilliancy. Although we have not yet been able to obtain mairogallol from jute, there can be no doubt that the similarity of the colour reaction, especially in view of the results of previous investigation, points to a close connection between the non-cellulose portion of jute and the trihydric phenols. Hitherto, we have been unable to obtain *any* crystalline bodies, excepting of course products of extreme resolution such as oxalic or protocatechuic acids, by any method of treatment; and this has of course added much to the difficulties of the work. Nor is it perhaps to be wondered at, that bodies which, forming as they do such an *essential* part of the plant structure, are of necessity amorphous, should yield only complicated amorphous derivatives.

The next most important point to consider is the action of sulphuric acid.

If jute be treated with a 10 per cent. acid, it first becomes disintegrated and then gradually dissolves. If the solution be distilled a product is obtained which is found to contain a large quantity of furfurol. In one case we obtained as much as 10 per cent. of the jute treated. The fact that so large quantity can be obtained by a somewhat simple treatment, indicates the aldehyde nature of the jute substance. In the light of this result we examined the stony concretions of pears which we had previously regarded as similar in constitution to jute. They very readily yielded a large quantity of furfurol. Erdmann, who had investigated these substances, came to the conclusion that they consisted of a body which he called glucodrupose, and stated that by the action of acids they yielded glucose and a substance call drupose; drupose itself being converted by the action of dilute nitric acid into cellulose.

In some modern text-books very symmetrical equations are given for the above decompositions, but it is clearly impossible to attach any importance to them, as they are constructed without any reference to such an important product as furfurol.

The aldehyde nature of lignified tissues has been of special interest to us in considering the theories involved in a process for the production of paper pulp from wood. The process consists in heating wood with a solution of bisulphite of magnesia at a pressure of about 90 lbs. to the square inch. We have had occasion to examine the liquors obtained as a bye-product by this process and have found that they consist chiefly of a solution of a complicated compound of the non-cellulose portion of the wood and magnesium sulphite. This compound is of very great stability and has, no doubt, an important bearing on both the theory and the practice of this process. The formation of such a compound is fully in accordance with the well-known property that aldehydes have, of forming compounds with the sulphites.

Of the exact nature of the change that cellulose undergoes during the process of lignification, but little is known with certainty, although a considerable amount of evidence exists of the conversion of cellulose and other carbohydrates into aromatic bodies and, therefore, incidentally of their conversion into lignose. For instance, it has been shown that by heating starch to a high temperature in presence of water pyrocatechin is formed. Under certain circumstances the "nitro"-celluloses, and even cellulose itself, may be converted into bodies of the pectic class, and metapectic acid has been proved to belong to the aromatic group, for it yields protocatechuic acid on fusion with potash. Perhaps the most convincing proof of the probability of such a change is shown by a study of the action of strong sulphuric acid on cellulose. By heating cellulose or dextrin, which is equivalent, for cellulose itself is first converted into dextrin, with strong H_2SO_4 at 70° C. it is converted into an insoluble black substance. The formation of this body has of course been frequently observed, but its nature does not appear to have been studied. Its *blackness* appears to have satisfied chemists that it was carbon, and the reaction has served for a very long time as a startling lecture experiment, the decomposition having been explained by a symmetrical equation showing how, by reason of the great affinity of strong H_2SO_4 for water, the carbohydrate was split up, carbon being left behind. As a matter of fact this black substance contains 60 to 70 per cent. of carbon only and that in combination with O and H. When acted upon by $KClO_3$ and HCl it is converted into a bright yellow chlorinated derivative perfectly soluble in alcohol and indistinguishable in appearance and general properties from that obtained from jute. The similarity in composition is also remarkable.

Dextrine.	Jute.
$C_{21}H_{18}Cl_4O_{10}$	$C_{19}H_{18}Cl_4O_9$.

When the original black substance is dried it forms a hard mass resembling coal. So close is the resemblance that we were led to examine coal from the stand-point of our previous work. We found that when treated in the same way with $KClO_3$ and HCl it was also converted, although with some reluctance owing to its compact nature, into a light brown chlorine compound soluble in alcohol. This ought to be sufficient to dispose of any lingering notions that coal is in any special sense carbonaceous. In many works coal is still spoken of as a form of carbon, but as we think with but little reason except its blackness.

There is another class of fibres to which I should like briefly to draw your attention.

Unlike jute they are not lignified, and therefore give no yellow coloration with aniline sulphate and no reaction with chlorine and sodium sulphite. They differ, moreover, in their percentage composition. Jute and fibres of that class contain a larger percentage of carbon than cellulose itself, whereas the class we are now considering contain less. We find, moreover, that on boiling with caustic soda solution a large quantity of the fibre substance is dissolved, and from the solution parapectic acid can be obtained as a gelatinous precipitate on adding an acid. This fact, together with the low carbon percentage, indicates that the cellulose has undergone a modification in the direction of the pectic group. Moreover, if such fibres be treated with a colourless solution of a so-called alkaline blue, which has but little dyeing action on jute, they very readily take on colour, showing that acid properties had been developed.

This observation has lately received a curious confirmation by an invention of a M. Witz, of Rouen. He has patented a process for so acting upon cellulose by means of oxidizing agents, that the portion treated shall possess the property of fixing certain colours.

We hope soon to be in a position to investigate some of the products M. Witz has thus obtained, and to which he gives the name oxycellulose. Before we knew of his patent, and, indeed, before it was published, we had published the result of an investigation of the action of oxidizing agents, chiefly nitric acid, on cellulose. We found if any form of cellulose is treated for some hours with 50 per cent. HNO_3, about 30 per cent. of it is converted into an amorphous body, which is perfectly soluble in solutions of alkali, from which it can be precipitated as a gelatinous mass, closely resembling pectic acid, and forming, when dry, a hard horny mass. To this body we had also given the name oxycellulose. It has invariably the same composition from whatever source it is obtained, and the results of the analyses point to the formula, $C_{18}H_{26}O_{16}$.

A comparison of the two bodies will be very interesting.

Such is a brief sketch of that particular branch of chemical investigation to which we have chiefly devoted our attention. The field is a very extensive one, and is as yet but little worked, but it promises a rich harvest of both theoretical and practical results to the investigator.

Mr. Davies, F.C.S., said he had listened to the paper with considerable interest, and had great pleasure in moving that the best thanks of the Association be accorded to Mr. Bevan for same, and he also thanked him for showing samples of the different chemical products—many of which were quite new—which had been produced in course of Mr. Bevan's experiments.

The discussion was continued by Mr. A. C. Abraham.

Mr. Smetham and Mr. Bevan having replied, the vote was carried by acclamation.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

An open meeting of this Association was held in the Pharmaceutical Society's Rooms, Edinburgh, on Wednesday, January 9, at 9.15 p.m. Mr. Claude F. Henry, President in the chair.

The minutes of the previous meeting having been read and confirmed, the President called upon Mr. Thomas Stephenson to read a paper.

The Shale Products Industry.

BY THOMAS STEPHENSON.

In an introductory portion of the paper the author briefly referred to the discovery of paraffin by Reichenbach, and the independent discoveries of Christison and Dumas. He then gave an interesting account of the work of the late Dr. James Young in establishing the industry, as recently noted in this Journal.*

The characteristics of shale were then described, the author stating that "there is no line of demarcation between shale and coal, as a series of minerals of an intermediate description is to be found, regarding which it would be difficult to say whether they were shale or coal; but the two minerals, although occasionally found associated, are, as a rule, found occupying different tracts of country. Coal yields on distillation tar or bituminous matter, which is used as fuel and for gas making. Shale, on the other hand, gives a distillate suitable for refining into burning and lubricating oils, these products constituting quite a different series of hydrocarbons from those obtained from coal."

The various products obtained from shale were then briefly described, specimens being shown in illustration. It was stated that different shales yield varying percentages of finished products, but the following are a fair average:—

Gasoline	0·25	per cent.
Naphtha	3·00	„
Burning oils	31·00	„
Lubricating oils	20·25	„
Solid paraffin	10·50	„
Loss	35·00	„
	100·00	

The skill or manner in which the process of refining is conducted considerably affects the yield.

He then proceeded to give the following account of the details of the process as it is carried on at the Oakbank Oil Works, near Midcalder, which he had an opportunity of visiting a short time ago.

"The shale is conveyed from the pits to the works by rail, a distance of about a mile. It is then passed through a breaker, which consists of two strong iron drums covered with strong iron teeth. These drums revolve against each other, the teeth passing through between each other. The shale falls between these drums and is consequently much broken up.

"After being broken it is conveyed in hutches, by means of a steam lift, to an elevated platform at the top of the retorts.

"These retorts are from two hundred and fifty to three hundred in number, and are arranged in sets of sixteen. They are charged by means of hoppers on the top, one hopper communicating with four retorts by means of a forked arrangement.

"The retorts used are known as 'Young and Beilby's.' Mr. Young, the manager of works at Pentland, and who, it may be mentioned, is no relation to the late Dr. James Young, the founder of the industry, and Mr. Beilby, the manager of Oakbank, each took out a patent about the same time for a new retort, and as both were very similar in construction and principle of working, it was arranged by mutual agreement that the patents should be conjoined, under the name of 'Young and Beilby's.'

"Each retort consists of a vertical cylinder, about 18 feet high, the upper part of which is made of iron and the lower part of fireclay. The lower ends of the retorts dip into a trough of water, which acts as a lute. Each set of sixteen retorts occupies one chamber, and is arranged on each side of the furnace in rows of four. The furnace does not reach higher than the fireclay portion of the retort, so that the upper part may not be exposed to too great a heat, the clay portion requiring a white heat.

"Besides the heat of the furnace a current of superheated steam is admitted to the fireclay part of the cylinder, and this helps to drive out the vapours as soon as they are formed, but it also serves another and more important purpose. The shale contains a quantity of nitrogen, which is held fast by the carbon. The purpose which the steam effects in the distillation is as follows:—It first of all enters the retort at the bottom of the clay portion, which, together with the shale contained in it, is exposed to a white heat. The steam is here decomposed. Its oxygen combines with the carbon of the spent shale (for the shale has been exhausted of oil before being permitted to enter the clay portion of the retort), forming carbon dioxide; while its hydrogen combines with the nitrogen previously held by the carbon, forming ammonia. This reaction takes place while the hydrogen and oxygen of the steam are in a nascent condition; but this chemical reaction, whereby we obtain the nitrogen as NH_3, must take place in the presence of a large excess of steam, which protects the ammonia as it is formed, and which, but for the presence of the excess of steam, would again be lost by decomposition. The excess of steam vapours now passes up into the iron part of the retort, and there greatly assists in the distillation of the oil from the shale, along with the ammonia obtained conjointly with the oil.

"The ammonia so produced has been found to be so valuable that it is in contemplation to recover it also from the ordinary coal used at present as fuel for heating the retorts, where, of course, the nitrogen is sacrificed. The plan to be shortly adopted, is to treat this coal in separate retorts, so as to produce coal gas, which is to be employed, along with the uncondensable gas from the shale, for the purpose of heating the shale retorts. The ammonia, of course, is secured in this process, and it is calculated that about 7*s.* 6*d.* worth of ammonium sulphate can be obtained from 3*s.* or 4*s.* worth of coal, so that the coal, instead of as formerly, being at the debit side of the account, will really prove a source of profit to the company.

"The shale is first heated to a low red heat in the iron part of the cylinders. In this way the oil is distilled. As the process goes on the shale subsides down towards the fireclay portion, where it is heated to a white heat by the naked flame of the furnace. It is here that it meets with the superheated steam which separates the nitrogen. By the time it reaches the water it has been thoroughly exhausted of all its value, and can be withdrawn from the bottom. The cylinders are charged from the top every three or four hours with raw shale, and on each occasion the fireclay portion is still full of partially or

* *Pharm. Journ.*, [3], vol. iv., p. 762; also present vol., p. 198.

entirely exhausted material. The advantages of this arrangement are mainly the adjustment of the degree of heat necessary to convert the whole of the shale into the desired products, instead of into gas, and in the production of ammonia, which, from a pecuniary point of view, is the most important product of all.

"Although the Henderson retort is not used at the Oakbank works, a description of it may not be out of place, as it is mentioned in all books on the subject as being the best and most widely used. It is, however, by this time entirely superseded by that of Young and Beilby. It consists of a vertical iron cylinder about 15 feet long Instead of a water-lute at the bottom, there is a door which opens into the furnace. The shale, after being exhausted of oil, is admitted, by means of this door, into the furnace, where it is utilized as fuel to a certain extent. The residual shale is different from all others, in that it has a reddish tinge and is very fragile. The great drawback of this retort is that in utilizing the carbon as fuel, the nitrogen, and, consequently, the ammonia, must be, in great measure, sacrificed.

"To return to the Oakbank process, the vapours, after leaving the retorts, are conveyed through a series of upright tubes fitted in a trough, where they are condensed and conveyed to a 'separator.' This is a tank with two exit pipes, one from the bottom and another from near the top. The oil, being lighter, floats on the surface and leaves by the upper opening, while the ammoniacal liquor leaves by the lower one.

"The gases, which have passed unaltered through the ordinary condensers, yield, on being subjected to pressure, or passed through a coke or spray tower, a very volatile liquid termed *gasoline.*

"The ammoniacal liquor, which is drawn off from below the oil, is led away to a separate house, where it is passed into a '*dephlegmating still,*' which consists of a vertical cylinder having a series of perforated transverse plates inside, which divide the ammoniacal liquor into small drops as it passes down. A current of stream is admitted into the still at the bottom. This lifts the ammonia, so to speak, and carries it away to the saturators, which are wooden boxes lined with lead, and containing sulphuric acid. The steam, carrying the ammonia with it, is passed through the sulphuric acid, which combines with the ammonia to form ammonium sulphate, the process being continued until the vapours begin to smell of ammonia.

"This liquid, which contains sulphate of ammonia, is removed to large vessels, where it is evaporated down by means of a coil of steam pipe extending throughout the liquid, the crystals being ladled out as they form. The sulphate is then removed to a drying shed, and, after remaining there for about a week, is ready for the market, and is sold at about £18 or £20 per ton, realizing a handsome profit.

"The *crude oil,* consisting of the solid distillate in the process I have detailed, is then distilled completely in stills which have cast iron pot-shaped bottoms, and which are capable of holding 1200 to 1400 gallons each. The distillation is effected by steam blown into the oil. The product is 'green oil,' a very fine pure coke remaining in the still.

"This green oil is subjected to treatment with sulphuric acid and caustic soda. In order that as little sulphuric acid as possible may be used, the oil must first be separated from water, as far as possible, as this would weaken the acid and thus cause more to be used. The oil is agitated with the sulphuric acid in cylindrical vessels furnished with paddles inside, the agitation being assisted by means of air blown up through the oil from a perforated coil of pipe in the bottom of the agitator. It is then run into other agitators of a similar construction, where it is treated with caustic soda. This treatment has the effect of reducing the specific gravity of the oil from ·860 to ·830–·845 ; and it also reduces its bulk about 15 per cent.

"It is then pumped into large cylindrical stills capable of holding 4000 gallons, and furnished with condensing worms, where it is subjected to fractional distillation.

"The *naphtha* first comes over, and is led away into a tank by itself. The *burning oil* next comes over and is also led away to a separate tank. The heavy *lubricating oil* is the last to distil over, and the residue in the stills again consists of *coke.*

"The naphtha is rectified by being first treated with acid and soda and then redistilled.

"The burning oil is also treated with acid and soda and redistilled, the first portion being mixed with the crude naphtha, and the last with lubricating oil, and they are both kept separate. The middle, or '*burning oil*' portion is removed to tanks where it is subjected to treatment with sodium carbonate. This has the effect of causing any solid matter held in suspension to fall to the bottom as a sediment, leaving the oil clear. In about twenty-four hours the bottom of the tank can be seen distinctly through the oil, which is then clear, bright and almost colourless.

"For the production of *paraffin,* the lubricating oil, obtained in the first fractional distillation, is allowed to cool, when the substance known as '*hard*' *paraffin scale* crystallizes out. This is separated by passing the oil through a series of sheets of canvas, stretched on iron frames, placed side by side in a long trough, forming an arrangement not unlike a toast-rack with the sides covered in. The scale is then placed between other sheets of canvas and subjected to hydraulic pressure, in order to separate as much oil as possible.

"The oil which is pressed from the scale is then led away to a refrigerator. This consists of a trough in which the oil is placed, and a drum which revolves in the oil, and which contains gasoline. The gasoline is evaporated by means of a powerful pump, and this evaporation so cools the oil, that all the paraffin it contains at once crystallizes out, and is scraped off by a fixed knife placed at the edge of the drum.

"This paraffin scale has a much lower melting point than the former, and is therefore called '*soft*' *paraffin scale.* It is separated from the oil in a manner similar to that employed for the hard scale.

"The oil which is separated from paraffin (called 'blue oil' from its colour) is then removed, and after treatment with acid and soda, and fractional distillation until the desired specific gravity is obtained, it constitutes '*lubricating oil.*'

"I have now only to allude to the further treatment of the paraffin scale.

"A quantity of the soft scale is mixed with the hard, to reduce its melting-point, but most of it is sold, to match manufacturers for saturating the wood in order to render it more inflammable. The scale is then washed repeatedly with naphtha, to dissolve out the oil, both naphtha and oil being afterwards recovered. After treatment with animal charcoal or some similar substance, it is melted and run into cakes, which constitute the well-known 'solid paraffin.'

"Vaseline has never been successfully manufactured from any of our shale products. It is got by a special process of filtration through animal charcoal, from the residue obtained after the distillation of the burning oil from American petroleum.

"The 'spent shale' consists principally of silica and alumina, with traces of iron, and has never been turned to any practical account. It accumulates in vast heaps close to the works. Perhaps these heaps, some of which weigh many millions of tons and tower to a height of several hundred feet, may prove a puzzle to our geologists a few centuries hence."

The paper was well illustrated by coloured sketches of working plant, tables of percentages and a full series of specimens, which those present had an opportunity of inspecting during an interval in the proceedings.

The President moved a vote of thanks to Mr. Stephenson, referring to the interesting manner in which the subject had beeen treated. The motion was seconded by Mr. Dunlop, and after several others had commented on the subject, Mr. Stephenson replied.

Mr. A. Robbie then read an exhaustive paper on "Cod Liver Oil," in the course of which he gave some interesting details of the cod fish industry as pursued in Newfoundland, Norway and the coast of Scotland. After referring to the various methods which had been employed from time to time for the extraction of the oil, he gave an account of the methods now adopted, and stated that the superior quality of Norwegian oil is rather due to better quality of fish livers than any superior method of manufacture. After commenting on the chemistry of the oil he noticed briefly its pharmacy and therapeutics and concluded with some remarks on the causes of the present small supplies of the oil.

The paper was fully illustrated by specimens.

A vote of thanks, moved by the President and seconded by Mr. Wood Ainslie, was heartily accorded to Mr. Robbie, and a discussion followed, in which Messrs. Crowden, Dunlop, MacEwan, and others took part.

This was all the business, and after the President had commented on the satisfactory manner in which two apprentice members had acquitted themselves that evening, he intimated that the next meeting would be held on the 30th instant, when a paper on the "Official Alkaloids: their Chemistry and Preparation" will be read by Mr. John R. Hill. The meeting then adjourned.

YORK CHEMISTS' ASSOCIATION.

The annual meeting was held on the 27th ult., at the rooms, High Ousegate. The proceedings were of a formal character. A resolution was passed expressing regret at the loss the Association has sustained by the death of the late President, Mr. Councillor Davison. The names of Messrs. Humphreys, Gubbetis and Boyes were added to the Committee. The following officers were elected for the current year:—President, Mr. J. Clark (of Messrs. Langton, Edden, Hicks and Clark, London); Treasurer. Mr. J. Sowray; Secretary, Mr. T. W. Hodges.

Parliamentary and Law Proceedings.

Poisoning by Hydrocyanic Acid.

Mr. S. Hacker held an inquest on Friday, January 11, at Newton Abbot, touching the death of Mrs. Jane Pinsent.

From the evidence it appeared that the deceased was found by her brother fully dressed, lying on her bed, unconcious and apparently dying. He gave her some brandy and applied a hot water jar to her feet, but she expired within ten minutes from the time he first saw her. On the mantelpiece he found a small dark bottle, with a glass stopper, labelled "poison." He inferred from that the bottle contained laudanum and that the deceased had poisoned herself. The bottle was here produced, and the label on it was as follows:—"Hydrocyanic acid (of Steele's strength), dose 1 to 4 minims. Layman and Umney London." Witness, continuing, said he believed the deceased was on the best terms with her husband and her mother; and although she had overdrawn her banker's account there was nothing for her to trouble about. In fact everything had been set right.

Mr. Scott, surgeon, said that he saw the deceased about six o'clock on the previous evening; life was then extinct, the deceased having to all appearances been dead for about an hour. Mr. May drew his attention to a bottle on the mantelpiece, which, on examining, he found to have contained prussic acid of twice the ordinary strength. and a small dose of which would be sufficient to cause death. He had no doubt, judging from the livid appearance of the body, that death had arisen from that cause. He subsequently made a *post-mortem* examination, which left no doubt in his mind that death was caused by prussic acid.

Mr. Bibbings, chemist, stated that the deceased had been a customer of his for about five years, and was consequently well known to him. On Wednesday morning, about 11.30, she entered his shop and purchased several articles. Among these she asked for some prussic acid, and said that she was going to poison a favourite dog which someone had given her, but which she did not wish to keep. He cautioned her, and told her not to let the poison go out of her hands on any account. She promised that she would be very careful with it, and he let her have about six drachms, just enough to kill a dog. He did not make an entry of the transaction in the book provided as he had known the deceased so long.

The Coroner here cautioned the witness as to future similar transactions, and witness promised to insist on the entries being signed by the applicants.

The Jury returned a verdict of "Suicide while in a temporary state of insanity."—*From the Western Morning News.*

Alleged Poisoning by Laudanum.—The Duty of Chemists in respect to Dirty Bottles.

On Saturday, December 12, an inquest was held at Maryport, before Mr. W. W. Lumb, Coroner, on the body of Mary McWilliams, aged ten weeks.

Elizabeth McWilliams, mother of the deceased, said the child had been ailing since birth. She got a pennyworth of mixture from Mr. Smith, chemist, Maryport, on Tuesday night. The bottle which she sent had contained laudanum, but nothing was in when she sent it. She gave the child the whole of the mixture at five times. It had the last dose nearly twenty-four hours before it died. She did not wash out the bottle which had contained laudanum, but drained it. She did not observe that there was any left in the bottle.

Dr. John Crerar said he was requested to visit the deceased on Thursday morning, about seven o'clock. His assistant went immediately, and from what was afterwards said to him he went himself in the forenoon. Dr. Crerar continued: I found the child very heavy and sleepy, skin pallid, pupils firmly contracted, and presenting the ordinary symptoms of opium poisoning. It had had convulsions, which are not infrequently present in cases of opium poisoning in infants, but it was denied that any laudanum had been given to the child. After some little time I elicited the fact that it had had something from a druggist. The bottle got at the druggist's was produced. It was empty, and labelled "Infant's Mixture." After directing the necessary treatment, though the case was apparently hopeless, I called at the druggist's, and found the stock bottle from which the mixture was supplied. It was quite innocuous. This was a little puzzling, but the fact that the child had had opium was clear. On partially removing the label from the bottle, a dark-red label was revealed underneath. This was marked "Laudanum—Poisonous," and was probably the source of the opium which had poisoned the child. The bottle belonged to the parties themselves, and had probably contained a portion of a previous purchase. The child undoubtedly died from opium poisoning. I could not, therefore, give a certificate. It should be well known to the public that opium, in all its forms, is a very dangerous and potent agent in the case of infants. Notwithstanding this, the administration of opium, generally as laudanum, to infants, prevails extensively. It is a favourite remedy with foolish mothers and ignorant nurses. Most of the soothing syrups and other remedies to quiet children contain laudanum as the active ingredient. They are very convenient and effective, but they are also a frequent cause of frightful mortality among infants. Some druggists wisely refuse to sell laudanum when the intention is declared to give it to young children. Others are not equally careful.

The Coroner said the jury ought to have the person who had served the mixture in the chemist's shop, and ascertain if there was anything like laudanum in the bottle at the time he put in the "Infant's Mixture."

The Jury agreed to this, and the inquiry was adjourned.

On resuming, Joseph Robert Comyns, of Furnace Cottage, Maryport, aged 17, who is apprentice to Mr. Smith, chemist and druggist, High Street, was called. He said he had been with Mr. Smith over three years. He did not remember a boy going to the shop on Tuesday night for a pennyworth of cough mixture, but he might remember the lad if he saw him. He did not recollect having seen the bottle produced before, although it had a label marked "Laudanum—Poison" on it.

The Coroner: Suppose you had seen a bottle with "laudanum" marked on it, what would you have done with it?

Witness: I should have seen there was no laudanum in before I put in the mixture.

I was just going to ask you that. Suppose the boy brought you the bottle and it was dirty, like this, would you have washed it out?—No, I should have simply seen that it was empty.

How many drops of this mixture are there in the bottle now?—Ten to fifteen drops.

And there might have been that quantity of laudanum in the bottle which you might not have noticed?—I should have seen that the bottle was perfectly empty. We never serve laudanum or any poisonous thing to children.

The boy, McWilliams, who purchased the mixture was called, but Comyns said he did not remember him. McWilliams said Comyns served him with the mixture out of a large bottle. In reply to the coroner the lad further stated that he was certain there was nothing in the bottle, because his mother had previously drained it into the grate.

The Coroner said they would all agree with him that Dr. Crerar was quite right in not giving a certificate under the circumstances. There was no doubt the child was poisoned, but so far as he could see there did not appear to be any blame attributable to anyone. Still it was clear there had been laudanum in the bottle when the mixture was put into it at Mr. Smith's. The fact that there was a laudanum label on the bottle should have put the young man on his guard, and all persons in druggists' shops should use the greatest care when such bottles were taken to them. They should either wash the bottle out before putting the stuff into it, or else take the dirty bottle and give a clean one, and afterwards wash the bottle at the shop. If there was blame in the case it was certainly on the young man Comyns, who should have washed out the bottle, or at least have taken greater care. Had he washed out the bottle or given a clean one, in all probability the child would have been living now. Dr. Crerar was perfectly right in withholding the certificate, as it was a proper case to be inquired into by a coroner and jury. He trusted that persons would read the evidence given in the case and act accordingly. They were all liable to make mistakes, but on that bottle there was a label which was sufficient to put any person on his guard and make him very careful. There was no culpable blame attached to anyone; it had only been carelessness. He thought the jury might make a recommendation, because there were many of those cases, that the greatest possible caution should be used, and that druggists and others should not put perfectly innocent mixtures into dirty bottles.

The Jury returned a verdict that the child died from poisoning by laudanum having been left in the bottle through the carelessness of both the mother and the druggist's assistant. They added a recommendation as suggested above by the coroner. They did not find anyone culpably negligent, but there had been a great deal of carelessness revealed, and druggists should be careful to either wash out the bottles when dirty or give new ones.

The Coroner said he thoroughly agreed with the remarks that had been made, and he hoped they would have a good effect on the public.—*West Cumberland Times.*

Reviews.

Plant Analysis: Qualitative and Quantitative. By G. Dragendorff, Ph.D. Translated from the German by Henry G. Greenish.*

This is a capital book, and one which we welcome as being a step forward in a much neglected branch of analysis. We have here a scheme of plant analysis which will be found of great assistance to students, who we fear have hitherto regarded plant analysis as quite beyond their border. The plan adopted by the author has been that of separating the constituents of the plant as far as possible by means of different solvents, thus following a method which is familiar to those conversant with plant analysis; but he has extended it so far as increasing the number of solvents and in varying the order in which the solvents are allowed to act on the substance under examination. In this way the plant constituents are separated, as it were, into six groups, which are obtained by the successive application on the plant material of the following solvents:—

1. Petroleum spirit (b. p. 45°), extracting ethereal and fatty oils, wax, etc., and, what is often overlooked, any chlcrophyll aud alkaloid dissolved in the fatty oil.
2. Ether: resins and their allies.
3. Absolute alcohol: resins, tannin, bitter principles, alkaloids, glucosides, etc.
4. Water: mucilage, acids, glucoses, saccharoses and other carbohydrates, albuminous substances, etc.
5. Dilute soda: metarabic acid, albuminous substances, phlobaphenes, etc.
6. Dilute hydrochloric acid: pararabin, calcium oxalate, and starch.

The material of the plant which remains may consist of lignin and allied substances and cellulose. Each extract is then exhaustively dealt with for the isolation of its several constituents.

In Part II. we find special methods for the estimation of certain constituents of the plant, it consisting, in fact, of supplementary notes to the first portion of the work. This part commences with a method for the estimation of fixed oils, and an account of their behaviour to reagents; then passes on to ethereal oils, resins, tannins, alkaloids, the sugars, amines, acids, albuminoids, starch, etc, and the work is completed by tables giving the percentage composition of the constituents of plants mentioned throughout the work, arranged in one case alphabetically and in the other according to percentage of carbon.

This, briefly, is the broad outline of the plan followed by Professor Dragendorff.

It is almost superfluous to say that the author has made the very best use of the material, insufficient as he deems it, at present available for the construction of a systematic process of analysis, and no one is more conscious than he of the necessity of sifting and improving the methods described. For this purpose the student will find copious references in foot notes to authorities or to papers; in fact, every page bristles with them.

To show the exhaustive character of the work, it may suffice to mention that for the determination of tannin

* London: Baillière, Tindall and Cox. Demy 8vo. Pp. i-xvi., 1-280. Price 7*s*. 6*d*.

in the absolute alcoholic extract there are no less than twelve methods passed in review.

It is to be desired that this redundancy of methods may not defeat its purpose and serve to perplex rather than to assist the student, and this it is very apt to do unless the student possesses more than ordinary discriminative ability. Where all is so satisfactory it would be supererogatory to particularize portions; but we may mention that the alkaloids are treated of very accurately and succinctly, and the methods for the separation of the cinchona alkaloids are, as far as they go, trustworthy, and leave no pitfalls for students.

The admirable manner in which Mr. Greenish has translated the work deserves more than a cursory notice. There is perhaps one hastily compiled sentence on page 63, where we read, "To the filtrate, together with 100 c.c. of wash alcohol, the results of two following extractions, each with 250 c.c. of spirit, and 100 c.c. washings are added." Again, China nova tannic acid is literally correct, but if chinovagerbsaüre be the word in the original, use has made us accustomed to quinovintannic acid in the same way as chinovasaüre gives quinovic acid. These, however, are only trifling blemishes that can easily be removed if the work reaches a second edition. Meanwhile we heartily congratulate Mr. Greenish upon the successful translation that he has furnished of a very valuable book.

Year-Book of Pharmacy: comprising Abstracts of Papers relating to Pharmacy, Materia Medica and Chemistry contributed to British and Foreign Journals from July 1, 1882, to June 30, 1883. With the Transactions of the British Pharmaceutical Conference at the Twentieth Annual Meeting, held at Southport, 1883.*

The "Year-Book" issued to the members of the British Pharmaceutical Conference is so well known and so fully described in its title, and has now been for so many years compiled by the same able editor, that little comment requires to be made upon the appearance of a new volume. If the one under notice varies in any respect from its predecessors, beyond being somewhat more bulky than usual, we think it is in containing a larger number of extracts, made more briefly than used to be the case, and in the chemical section covering a wider field. The comparative paucity of important communications upon the vegetable materia medica is noticeable, and quite confirms a remark made in our recent summary of the year 1883. The volume is prefaced by the usual sixteen pages of "Introduction," which, by the way, it is difficult to keep free from an appearance of cataloguing, and there are about the same number of pages devoted—rather wastefully—to the section of "Bibliography." The latter part of the volume, consisting of the report of the meeting at Southport, has already been published in this Journal. A few errors have crept in here and there, as indeed they will in spite of careful reading. Thus the quotation of an English abstract of a French paper through a German journal, on p. 92, has resulted in shortening the name of an author by a syllable; but he is more fortunate than Mr. Thiselton Dyer, quoted on p. 215, who is robbed of his surname altogether. Readers who are partial to symbolical conundrums will find a nut to crack on p. 553.

Notes and Statistics of Cinchona Bark. By John Hamilton, F.S.S. Second Edition.†

On the appearance of the first edition of Mr. Hamilton's pamphlet we took the opportunity of referring at length to some of the information contained in it. The statistics have now, in respect to the leading countries, been brought down to 1882, and in one or two cases to the middle of 1883, while the number of pages has been quadrupled by the addition of various interesting items of information concerning the cinchona plant, wild and cultivated. From the statistics it is seen that Great Britain continues to be the most important centre of the bark trade, the quantity imported into the United Kingdom having amounted to 15,599,920 pounds, or upwards of a million and a half pounds in excess of the imports of the previous year, this excess being equal to three-fifths of the total imports in 1871. Of this quantity the author estimates that as much as 6,638,352 pounds was reserved for home use. It is not quite clear how this figure has been arrived at, but by deducting the exports (8,961,568) from the imports (15,999,920) one exactly 400,000 higher is obtained. France is said to have imported during the same time 10,063,319 pounds and consumed 4,866,081. The other large consumers are Germany, which is credited with having used 5,674,680 pounds, and Italy with 6,150,000 pounds. The United States again shows a falling off of about half a million pounds in its import of bark, which in 1882 did not reach two-thirds of the quantity imported before the abolition of the protective duty on quinine.

In looking through these statistics it becomes evident that they can only be accepted as representing the facts approximately, and even for this result the author is entitled to considerable credit. They are, however, sufficient to show that—apart from such incidents as the advent of a new bark, like the cuprea, on the market—the demand is keeping place with the increased supply, and that there is not much probability that for several years to come the yield of wild and cultivated barks united will be in excess of what is required.

Correspondence.

The Botany of Cinchona Ledgeriana.*

Sir,—On May 3, Mr. J. E. Howard read a paper on this subject before the Linnean Society, and within the four months following he has found it necessary to publish two additional papers† to endeavour to explain successive changes in his opinions. These changes have resulted from "new light" obtained in instalments from different sources and of varying brilliancy:—the specimens and publications of Mr. T. N. Christie, of Ceylon, the visit of Mr. Ledger to England, and the publication of Mr. Moens' 'Kina cultuur in Azië.' Now, at length, the first paper is published,‡ considerably shorn of whatever importance it may have originally had; but this also has an "addendum," undated, but apparently written in August. It may be regretted by some Fellows of the Society that the author did not refrain from printing views which he had so modified since he expressed them. I presume, at all events, that in endeavouring to ascertain what really are Mr. Howard's present ideas on the nature of *C. Ledgeriana* (no easy task), I shall be right to take the statements and suggestions contained in the paper latest in date, that, namely, which, under the rather sarcastic heading of a "Brief Note," he contributed to your columns. To assist the exegesis I shall, however, have to avail myself of the earlier papers also.

When in September, 1881, I prepared the description of *C. Ledgeriana*, Moens, MSS., which was printed in my

* This communication was written more than a month before Mr. Howard's lamented death, and two before the news of that sad event reached Ceylon. The delay in its publication has been due to the kindness of the Editor, who forwarded me a proof, thinking that under the circumstances I might wish to revise it. It is probable that I might have availed myself of the opportunity and made a few verbal alterations, were it not that, after having allowed sufficient time to elapse for, as I supposed, the appearance of the paper in this Journal, I forwarded a copy to the *Ceylon Observer*, and in this it was published on November 26 last. Under these circumstances I leave the paper unaltered as written.—H. T.

† *Planters' Gazette*, August 16, 1883, pp. 983-4; and *Pharmaceutical Journal*, September 1, 1883, pp. 178–180.

‡ *Journ. Linn. Soc.*, xx., p. 317 (issued Sept. 24, 1883).

Journal* for November, the only published botanical information was Weddell's description in Howard's 'Quinology.'† It does not appear whether Weddell saw any specimens, or whether he drew up his diagnosis merely from Fitch's three fine drawings made from dried plants from the Java plantations; he allows that the characters he gives are "not weighty ones," and, indeed, those plates would not be sufficient alone for discriminating *Ledgeriana* from Calisaya.‡ The plant thus remained as very probably merely one of the pseudo-varieties of the bark-dealers which might not possess any botanical characters sufficiently definite to be able to be distinguished in the field or in the herbarium. In Java no doubt they knew better even then, but that was the state of information prevailing in England and India when I came to Ceylon at the beginning of 1880; and to the frequent and urgent requests of the growers of bark-trees to say whether such were "*Ledgeriana*" or not I found it impossible to give any positive answer.

Mr. Moens visited Ceylon in September, 1880, and it is to him I am indebted for having first pointed out to me that the plant had good definite characters. These were familiar to him in Java as distinguishing all the best and most marked trees which had come from Ledger's seed,§ and so soon as I was satisfied that they held good in Ceylon I lost no time in making them public. My description was based on the examination and comparison of numerous fresh specimens; and it was an additional proof of the correctness of the name, that the plants yielding them have all without exception been traced back to Ledger's seed.

In making (after consultation with Mr. Moens) Weddell's variety into a *species*, I expressed some compunction for adding yet another specific name to this already overburdened genus, but I gave what I thought good reasons for the course followed and I may now add that further experience has justified it.‖ Mr. Moens' own description has now appeared;¶ it is much fuller than mine, but differs in no other respect from it.

Yet Mr. Howard asserts in his two earlier papers that my plant is not *Ledgeriana*, but a variety of *C. micrantha*. It is true that in his most recent paper he acknowledges he "may be mistaken" in this extraordinary determination; in making it one can only suppose that he could not have read my description with any care; but, looking only at the figures accompanying it and remembering a former error of his own,** at once accused me of a similar blunder. But having supplied a full definition I must be judged by that rather than the plates accompanying it. I expressed in the paper my regret that I should be forced to figure so poor and ill-grown a specimen, but it was the best I could get at the time, and the tree, apart from its stunted growth, was considered by Mr. Moens as a very characteristic example of the species. Mr. Howard, further, has matched these figures of mine with one published in August, 1873, in the *Bot. Magazine* (tab. 6052) under the name *C. calisaya*, var. *Josephiana*, Wedd. This figure was made from a plant which flowered in Mr. Howard's conservatory in 1872, having been received from Kew. In the text accompanying the plate, Dr. (now Sir) J. D. Hooker tells us that the plants were brought from South America, by Pearce, in 1866, and that several wardian cases of them were sent to India in that year. He also says that it seems to be "intermediate between *Calisaya* and *micrantha*," but that Mr. Howard, after first thinking it var. *calisayoides* of the latter species, afterwards agreed with Dr. Weddell in calling it *Josephiana*. Mr. Howard now says, "I should myself have preferred calling it *C. micrantha*, var. *calisayoides*;" but it is remarkable that in 1876, when he himself published another figure ('Quin. Ind. Plant,' t. 9) of identically the same plant in his green-house, he should still give it the name of "*Josephiana*, var. *glabra*." Nor in the accompanying text (p. 86), does he say a single word about it being more properly a variety of *micrantha*. Both these plates show a plant with large erect white flowers and clavate buds; and what resemblance Mr. Howard can have seen between them and the figures accompanying my paper I fail to understand. No wonder Mr. Ledger "rejected" this plant. Mr. Howard does not tell us why he prefers to put it under *micrantha*: so far as the leaves go, it seems more rightly put under "*Josephiana*," where I see Mr. Moens also places it.* Ripe fruit would help to determine this point.

Of the other (or the same?) recorded intermediates between *Calisaya* and *micrantha*, extremely little is known.† Of the one called *C. Calisaya*, var. *pallida*, Wedd., no description or figure has been published; of the other, called *C. micrantha*, var. *calisayoides*, a very brief diagnosis by Weddell is all that we have. They are allowed to approach one another extremely closely in foliage, and the bark of each seems to have been called "*Calisaya blanca*," but I have no means of determining whether they be identical.

The next point Mr. Howard remarks upon is that no analysis of the bark of the tree figured by me was given, and appears to think this a serious omission. Can he mention any other genus of plants where it is necessary to give such an analysis in describing a new species, and if not, why should it be required in *Cinchona*? However important it may be in other respects, I attach no value to chemical composition as defining species or varieties. We know, indeed from experience, that out of ten trees with the characters Mr. Moens and I have pointed out, probably nine will yield a large, though variable, percentage of quinine almost unmixed with the other alkaloids; but the other one may be as poor as an ordinary *Calisaya*. It is true that the bark of the actual tree figured was never analysed; but it was one of a row of several, all of precisely the same botanical type, and the analysis of the bark of some of these has been published by Mr. Agar, the proprietor.‡ The analysis, as it happens, was made by Mr. Howard, "who pronounced it to be *Ledgeriana* bark."

Now, as to the magnificent pictures illustrating or forming the basis of Weddell's diagnosis of var. *Ledgeriana*; they are no doubt fine examples of Fitch's work, and one cannot but admire the skill which can produce such restorations from the dried mummies in a herbarium. But it is risky work, and the botanist is but too familiar with the want of that sort of accuracy which he particularly needs, so often to be seen in the work of even the best botanical artists. In these plates none of the characteristics of the flower of *Ledgeriana* are accurately shown so as to be beyond dispute; the points missed are just such as would be likely to escape an artist unless his attention were drawn to them, and they were not then known to Mr. Howard himself. Nor has the artist caught the *facies* or habit of the plant any better than the details (as may very well be seen by comparison with the phototypes illustrating Mr. Moens' 'Kina cultuur'), whilst the gaudy and inaccurate colouring makes them still less like reality.

It is necessary to say thus much about these plates, because Mr. Howard seems to regard them as so accurate as to justify him in speaking of them as though they superseded type specimens of plants themselves. This appears when we endeavour to ascertain what, after all, he considers his var. *Ledgeriana* to really be botanically. It is, he says, to be restricted to "the *Rojo* bark of Ledger," which is "one of Dr. Weddell's second division of *C. Calisaya*;"§ further, it is Howard's "form A. (plate iv.),

* *Journ. Bot.*, xix., pp. 321–325.

† 'Quin. Ind. Plant.,' p. 85.

‡ Mr. Howard himself candidly avowed that, to him Ledgeriana's character was stamped "by its great productiveness in pure quinine" (*l.c.*). Dr. Weddell did *not*, however include this in his definition.

§ It is perfectly well known that this seed was not all the same. There were some very bad trees of quite another type among those from the original sowing.

‖ The dignity of "species" varies considerably in different genera, their characters being inevitably lighter in such very natural genera as *Cinchona*. In fact *C. Ledgeriana* is pretty much on a level with most of the other accepted species in the genus.

¶ 'Kina cultuur in Azië,' pp. 75–77.

** See his paper, *Jour. Linn. Soc.*, p. 319.

* 'Kina cultuur,' p. 84.

† This little is to be found in the introduction to Howard's 'Illustrations,' p. v., and in Weddell's 'Notes,' in *Ann. Sc. Nat.*, ser. 5, xi., 361, and xii., 51 and 57. Triana (*Nouv. Et.* pp. 62, 75) puts both under *C. micrantha*.

‡ *Ceylon Observer*, June 24, 1883. They gave 7 per cent. pure quinine and only a trace of other alkaloids, being then four and a half years from planting out.

§ That is of an amplification by Howard of *C. Calisaya*, var. *microcarpa*, Wedd., described in *Ann. Sc. Nat.*, *l.c.*, p. 54, with the vernacular names of "*Calisaya Zamba*" and "*Zambita*."

exclusive of B. and C." (plate v. and vi.), and therefore only in part the var. *Ledgeriana* of Weddell and the *C. Ledgeriana* of Moens. In fact it is a *picture* (plate iv.) merely, selected it would seem, by Mr. Ledger, as the most like what he remembers or supposes these "*Rojo*" trees to be; that is all. This plate represents a robust plant with large erect flowers.

But Mr. Howard's restricted *Ledgeriana* is still further narrowed down. Plate iv. happens to have been made from a short-styled plant, and it chances that Dr. Weddell's diagnosis was also drawn up from one. Mr. Howard prefers, with the natives, to call this form "macho," and really believes that it is *male* in some more especial manner than the long-styled form, which the untutored Indians and he term "hembra" or female. It seems scarcely credible that he can seriously propose to restrict his *Ledgeriana* to the short-styled state, but he distinctly says that "it is exclusively the *macho* form." Mr. Howard has been led to the *reductio ad absurdum* of giving a definite botanical name to a mere sexual condition probably incapable of self-fertilization, simply on the faith of Mr. Ledger's opinion as to plate iv. The latter gentleman (or rather his native servant) was also much struck with the *colour* of another plate (tab. x.) representing the hybrid, *C. anglica*. This reminded him of the colour of "Rojo," and Mr. Howard at once jumps to the conclusion that the two are "very nearly related;" but as this plate x. happens to be drawn from a long-styled form, or "is very decidedly *hembra*," as Mr. Howard puts it, it "cannot come under Weddell's diagnosis."

We may, however, feel very certain that Dr. Weddell, in 1875, when he drew up the definition in question, was not intentionally creating a variety on what was then well known to be a merely physiological condition; to support the position that he did so, Mr. Howard quotes remarks written by that excellent botanist in 1849 when the nature and relationships of dimorphic or heterostyled flowers (so frequent in *Rubiaceæ*) were not properly understood; it is noteworthy that in 1869 Dr. Weddell had deliberately dropped the bark-cutter's term "macho," which he then no doubt saw to be misleading.

One sees with regret throughout all these communications of Mr. Howard, a very remarkable neglect, or an intentional defiance of the accepted rules of botanical nomenclature. For instance, he makes the astounding remark that "it belongs to Mr. Ledger and to him alone to define what is the true *Ledgeriana*." Why? On what possible grounds? Mr. Howard has said a little before, and fairly enough, that "the privilege of naming a plant belongs to the botanist who first observes and properly describes it;" this may pass, but how in the world can it apply to Mr. Ledger?

In conclusion, a few words as to the Ceylon cinchonas spoken of by Mr. Howard. He has committed himself to the following identifications:—(1) the plant figured by me = *C. micrantha*, var. *calisayoides* (probably); (2) Mr. Christie's specimens (S. Andrew's Estate) = *C. Calisaya*, var. *microcarpa* (but probably hybridized with *C. officinalis*); (3) Mr. Laurie's (Yarrow Estate) = *C. Calisaya*, var. *Ledgeriana*. Now, I am familiar with these. They are all from the same small quantity of seed, and were raised in the same nursery beds at the same time, and I can state positively that they are *all botanically identical*. Further, they are also identical with what is and always has been known as *Ledgeriana* in Java, and as *Ledgeriana* (species or variety) was founded on the plants in Java and has never yet been applied to any wild South American tree, the Ceylon plant must of course bear the same name. I regret the amount of ink—shed over so simple a matter.

Peradeniya, Ceylon. HENRY TRIMEN, M.B., F.L.S.

THE SOLUBILITY OF CALCIC HYDRATE.

Sir,—In a valuable paper by Mr. Maben on the solubility of calcic hydrate, published in the Journal of December 29, that gentleman, whilst to some extent confirming the results which I communicated to the Liverpool Chemists' Association, in November, 1882, differs from them in some respects, and produces figures so contrary to what might be expected that I have thought it right to make some further experiments.

The most important and startling statement is as follows:—

"I have found that lime-water can be made of full strength with calcic hydrate mixed with 15 per cent. of carbonate; with equal parts of hydrate and carbonate I obtained ·5 grain CaO per fluid ounce; with 25 per cent. hydrate and 75 per cent. carbonate ·4 grain, and with 10 per cent. hydrate and 90 per cent. carbonate the amount dissolved was only ·1 grain."

On reading this it at once occurred to me that Mr. Maben had either used an insufficient quantity of lime, or had not given sufficient time for the saturation to take place with the smaller proportions of hydrate.

To test this I had some fresh hydrate of lime prepared, and mixed this with the various percentages of precipitated chalk indicated by Mr. Maben. These mixtures were taken in such quantity that in every case the same proportion (viz. 100 grains) of the hydrate should be present with each pint of distilled water; practically the proportions of the Pharmacopœia.

These mixtures were shaken occasionally during an hour or two and then set aside for twenty-four hours, after which 2000 fluid grains were drawn from each with a pipette and estimated. The results are shown in the table.

No. of sample.	Percenrage of $CaCO_3$ present	Constituents used with 1 pint of distilled water. $CaOH_2O$.	Constituents used with 1 pint of distilled water. $CaCO_3$.	Fluid grains of $\frac{1}{2}$ strength. Vol. sol. oxalic acid required for 2000 fluid grains.	Redueed to terms of B. P. standard, viz., 200 fluid grains for 10 fluid ounces.	Temperature.
1	15	100	17½	195	213·28	62°
2	50	100	100	198	216·56	62°
3	75	100	300	195	213·28	62°
4	90	100	900	195	213·28	62°
5	Obtained by filtering from No. 1. and 2.			188	205·62	62°
6	Sample taken from lime in use one or two years; at least the former.			182	199·06	61°

These results would appear to show—

1st. That Mr. Maben's figures, taken without qualification, are not correct, and

2nd. That the Pharmacopœia standard is a fair one.

As to the first conclusion, I would not, for a moment, deny the possibility, or even probability, of calcium hydrate being so kept (especially if in coarse powder) as to become so covered upon the surface with carbonate, or converted perhaps into the hydro-carbonate, as to yield little to water. Mr. Maben does not, however, state that his hydrate had become deteriorated in this way, and we are, therefore, left to assume that he expected to get an equally saturated solution, either with an insufficient quantity of hydrate or that he did not allow sufficient time.

With regard to the second conclusion, I may say that the lime water drawn off with a pipette, although it had been allowed to stand for double the time directed by the Pharmacopœia, was not bright, and I impute the difference between No. 5 and those above (especially No. 2) to the presence of suspended matter. Even, however, with this deduction the figures would appear, at first sight, to confirm the B.P. standard, but I believe they do no such thing, except in so far as an impure lime water is concerned. I have before found that lime water from fresh lime was stronger than that made from well washed lime, and I have no doubt that this is due to the presence of hydrate of potash or soda formed during the burning of the lime from the sulphates or chlorides of these bases no doubt present.

Mr. Maben's method of filtration at different temperatures is not unexceptionable and a consideration of the difference in the parts of water required at temperatures differing by 5° C. will, I think, show that there is some discrepancy; commencing with the difference between 0°—5° they are as follow:—5, 6, 9, 12, 40, 31, 47, 23, 53, 34, 85, 32, 72, 27, 78, 49, 26, 191, 71, 0. These figures would produce a very erratic curve of solubility.

I see no reason to prefer the decinormal nitric acid to the half strength oxalic acid, the precipitate found by the latter rather increasing than diminishing the facility of use. Moreover to standardize the former is a troublesome operation. I trust that Mr. Maben will not suppose that I underrate the value of his paper, on the contrary, the interest which it conveyed prompted me to repeat, perhaps in a different form, the experiments which he mentions. The fact that he practically confirms Dalton's solubility, 1 in 778 (at 60° F. not 15° C.), confirms my results, and the fact that the sample (6) in the above table was taken from lime from which probably quite 100 gallons of lime water had been made shows that such an arrangement as I described in November, 1882, admirably answers its purpose.

My original statement that "at 70° the solubility is reduced not far from 10 per cent." was, no doubt, putting the difference rather high, although I consider that a standard 10 per cent. below the Pharmacopœia is not too low to adapt as a minimum.

In conclusion, sir, I would beg to point out that I did not, as would be inferred from your retrospective remarks upon the year 1883, suppose that temperature was the cause of the deficiencies in the strength of lime water for which prosecutions had been instituted.

Nor do I think that Mr. Maben would say that the temperature of a shop rarely rises above the point at which the official strength of lime water can be maintained, for his own figures show that at 86° F. (30° C.) the strength would be only ·51 grs. in the ounce.

From my own experiments I should be inclined to think that the presence of magnesium or silicate of calcium in commercial lime (which is indicated by the Pharmacopœia description) is the greatest source of the deficiencies which have been shown in Court.

Liverpool. A. C. Abraham.

Influence of the Electric Light on Plants.

Sir,—More than a year ago, on observing in several newspapers and journals notices relating to the growth of wheat by means of the electric light (also lately alluded to), I resolved to make some investigation into the matter, as I doubted the statements which had been recorded on the subject.

Our first experiment was made with some good sized potatoes. A few of these were placed in a position where they were exposed to the full glare of an electric light during the whole of the night, though in the daytime the place which they occupied was kept quite dark. The remaining portion of the potatoes was laid down in a continually dark place, but enjoying a similar amount of space for air circulation and exactly the same temperature as those on which the electric light flared.

When the potatoes had pushed growths about 5 inches in length they were removed and examined in broad daylight. The growths of both lots equal in length bore the same general appearance, and completely resembled the growths of potatoes which had lain for some time in a dark cellar or in the bottom of a stowed-away barrel.

I examined with great care those which had vegetated under the influence of the electric light to see if the growths possessed any green colouring matter (chlorophyll). But not the faintest stain or tinge of this could be seen, so that the great principle which either directly or indirectly builds up, nourishes and develops all the higher forms of plants and trees and ripens and colours fruits and seed pods was found to be absent. Chemists may analyse and identify the electric light with the rays of the sun in whatever way they please, but it is quite evident that the latter is something altogether different. I venture to assert that the electric light, even if perfected to a far higher degree than it at present is, will not be found to influence in the most remote way the development of even any of the lowest forms of vegetation. The opinion, therefore, which has been expressed of its value in accelerating and assisting the growth of plants and ripening of fruits is simply a delusion.

Anyone can satisfy himself of the matter by making a trial such as I have described. Large rapid growing seeds planted in loam and watered will answer the purpose just as well as potatoes, only that the latter can be laid about anywhere and demand no special attention.

Cramond Village, by Edinburgh. Robert Cross.

Patent Medicines containing Poison.

Sir,—When one remembers how numerous have been the letters which have appeared upon this matter in your Journal during the past two or three years from correspondents in all parts of the country, and the frequent articles which you have devoted to the same subject, together with many discussions upon certain clauses of a proposed amendment to the Pharmacy Act, in which an important alteration is proposed in the sale of all patent medicines containing scheduled poisons, and in the matter of defining a responsibility with regard to such sale, it may perhaps be excusable to remind Dr. Connell that with such evidence before him it will be impossible to charge the pharmaceutical body with any want of interest in this direction or with any laxity in their determination to effect a revolution if possible.

Dispensing chemists generally will be only too ready to co-operate with the medical profession in the endeavour to carry out any reform which would operate for the public good; and Dr. Connell may feel perfectly assured that there is no class of men more earnestly desirous of an expurgation of, this and other flagrant abuses than pharmacists, and not one which suffers so much from the uncertainty of being responsible for that to which no legal responsibility is accorded,

Although it still remains possible for "grocers, oilmen and others to sell medicines of which they know absolutely nothing," it has always been a serious question to me as to how far a qualified chemist is justified in sheltering himself behind the patent medicine exemption clause of the Pharmacy Act, for whilst through ignorance the grocer or the oilman has absolutely no responsibility, the chemist has morally, at the present moment, as much as he will ever have, except that it remains legally undefined. If therefore, the chemist should persist in retailing particular medicines (so-called patent) which have in his experience supplied the occasion for a coroner's inquiry, without a printed caution as to the uncertain nature of the compound, it appears to me that he accepts unreservedly the possibilities of a humiliating interrogatory, from the results of which no patent medicine clauses could shield him.

Kilburn, N.W. Charles B. Allen.

The late Dr. Carruthers.

Sir,—There are probably many in this neighbourhood, who, like myself, have vainly looked for some obituary notice of the death of poor Dr. Carruthers. But I suppose that beyond his immediate neighbourhood the highly interesting facts of his career in pharmacy, as well as the extraordinary circumstances in relation to his fatal accident, have not penetrated. From an obscure market town in Cumberland, where he had creditably served the usual term of apprenticeship, he came up to London, and duly passed the Minor examination about ten years ago. Then advancing still he received another well deserved honour in the shape of the membership of the Royal College of Surgeons.

It should be remembered, however, that for a time he was in business as a chemist and druggist, at Moss Side, Manchester, whence he succeeded in qualifying himself for the medical profession. And just when he was entering the threshold of an apparently prosperous career, and whilst administering professional assistance to some of the sufferers during the late great storm, a further downfall of chimneys took place, when he was struck down with injuries which resulted fatally after a brief period. His friends here are practically carrying out their appreciation of his heroic and Christian career by raising a fund for the benefit of his young wife and family, and they hope to realize, at least, £2000.

THE SALTS OF NARCOTINE.*

BY DAVID BROWN DOTT, F.R.S.E.,

Pharmaceutical Chemist.

The subject I have chosen for discussion in this short paper has not, at first sight, a very obvious interest for pharmacists, but, I think, further consideration will show that it has a bearing on pharmacy in two ways. These are, firstly, the importance of narcotine on account of its presence in nearly all the Pharmacopœia preparations of opium; and, secondly, the possibility of its salts passing into therapeutical use.

No one can have studied, ever so slightly, the literature of opium and its assay, and have failed to observe how frequently narcotine has been to the chemist a stumbling block and source of trouble. We need not now discuss in what various ways this has arisen. Although it is now many years since Regnault and Robiquet prepared and analysed the muriate of narcotine, there is still a prevalent idea that narcotine is not an alkaloid at all, or, at any rate, that it does not form well-defined salts. In support of this statement it would be easy to select suitable quotations from several writers, but I shall take as my text the following from Professor Flückiger: †—"The narcotine is present chiefly in the free state, as it is not really an alkaloid; it is, therefore, not, or not entirely, removed by water. With acetic acid, as well as with other acids, narcotine forms not well-defined salts; the acids are simply solvents from which it again separates as soon as the acid is neutralized." This is for the most part erroneous, as we shall very soon see. Let us first consider the various salts and their properties, so far as our knowledge goes.

Meconate.—This salt first engages our attention, as it is almost certainly the form in which narcotine exists naturally in opium. When narcotine and meconic acid are dissolved together in water, in molecular proportions, *i.e.*, two molecules of the base to one of the acid (which is di-basic), a syrupy solution is obtained which refuses to yield crystals. If evaporated, the salt dries as a varnish. Unlike most amorphous salts this is not readily taken up by water. When the proportions for the acid meconate are used, a clear viscous solution is obtained. This ultimately becomes filled with crystals, but I have not yet ascertained whether they are really a crystalline acid salt, or only the neutral salt with separated acid. "The books" give no information about these meconates.

Acetate.—This is one of the only two crystalline salts mentioned by the older authorities. According to Berzelius, it is prepared by "dissolving narcotine in concentrated acetic acid, and evaporating *in vacuo* in presence of lime." We prepared a quantity of acetate according to these directions (leaving out the lime). Narcotine will not dissolve in an equivalent of glacial acid; indeed, a clear solution was only obtained by warming with several times that amount. On cooling, the solution before long became filled with crystals, which were strongly pressed, first in calico and then between blotting paper. The crystals were immediately bottled, and two portions weighed off as quickly as possible. One of these was mixed with ten times its weight of calcic hydroxide, and exposed in the water-bath, while in the other the narcotine was determined by precipitation with ammonia.

23·04 grs. lost in w.-b. 0·36 gr. = 1·56 per cent.

26·45 grs. treated with cold water left undissolved 24·28 grs. By NH_3 0·66 gr. was obtained in addition, making the total narcotine = 94·29 per cent.

		Calculated.	Found.
$(C_{22}H_{23}NO_7)_3.C_2H_4O_3.H_2O$	$\overset{+}{N}$	94·07	94·29
	H_2O	1·36	1·56

Whence it is probable that the salt obtained as just described has the above composition. In any case, it is of no value on account of its insolubility in water, or (what amounts practically to the same thing) its immediate decomposition by water.

Hydrochloride.—The dry salt was correctly described by Regnault and by Robiquet, but they make no mention of water of crystallization. Dr. Wright was the first who fully investigated this salt, and our analysis leads to the same conclusion, that the normal hydrochloride has the composition $C_{22}H_{23}NO_7.HCl.H_2O$. Strong solutions of this salt show a curious tendency to gelatinize, like the salts of cryptopia. The muriate of narcotine may be regarded as its most important salt, being easily prepared and fully soluble.

Sulphate.—I have not been able to find any published reference to this salt, which is readily obtained by dissolving narcotine with the theoretical proportion of sulphuric acid and allowing to crystallize. Some of these crystals were dried by exposure to the air, and a weighed quantity of the air-dry salt placed in the water-bath.

14·55 grs. lost 0·10 gr. = 0·68 per cent.

Two portions of same salt dissolved in water, excess of ammonia added, and the precipitates collected and weighed.

17·200 grs. gave 14·30 grs. = 83·13 per cent.

6·555 grs. gave 5·45 grs. = 83·14 per cent.

14·55 grs. dried at 130° C. gave only 78·35 per cent., indicating decomposition at that temperature.

The salt dried in water-bath lost weight further in the air-bath at 120°. 9·74 grs. lost 0·675 gr. = a loss in weight of 6·93 per cent. on the air-dry salt.

From the results obtained it was suspected that the sulphate used in these experiments had been over dried by too long exposure to the air. A quantity of it was therefore moistened with water, and when apparently just dry was transferred to the water-bath.

9·740 grs. lost 1·48 grs. = 1·48 per cent.

It would, therefore, appear that narcotine sulphate has the composition $(C_{22}H_{23}NO_7)_2.H_2SO_4.4H_2O$, and that it loses one molecule of its water below 100° C., the remainder at a higher temperature.

		Calculated.	Found.
$\overset{+}{N}_2H_2SO_4.4H_2O$	H_2O	7·22	6·93
$\overset{+}{N}_2H_2SO_43H_2O.H_2O$	H_2O	1·71	1·48
"	$\overset{+}{N}$	82·93	83·13

We have not prepared any other salts besides these, and it is indeed unnecessary to do so. The meconate, muriate and sulphate dissolve completely in water, and their solutions remain clear even when largely diluted. Not so the acetate. By adding hot water to a solution of narcotine in dilute acetic acid, the greater part of the alkaloid is precipitated. One thing is noticeable regarding all salts of narcotine, that their solutions are *acid*, *i.e.*, they behave

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, January 16, 1884.

† 'Year-Book of Pharmacy,' 1879, 543.

as if they contained free acid. This I have no doubt they do, in common probably with all acid solutions of salts. When such a solution is shaken up with a solvent capable of dissolving the base, some of the base is taken up; as when a solution of narcotine muriate is agitated with ether. The process may perhaps be expressed in this way:—Narcotine, hydrochloric acid, and water have each an affinity or attraction for the others. When narcotine muriate is dissolved in water, the latter attracts the acid so as to cause a certain amount of decomposition in the salt, the affinity between the base and acid not being strong enough to resist the action of the water. Yet this affinity is sufficient to prevent any great decomposition, such as we have in the case of the acetate, where the addition of water causes an almost complete precipitation of the alkaloid. A kind of equilibrium is established, depending, no doubt, on the relative masses of the different components. When a portion of one of these is removed, as narcotine by benzine, the equilibrium is disturbed and rights itself by a little more decomposition, and so on. But it is not necessary to have the salt in solution in order to remove the base by an appropriate solvent. So weak an alkaloid is narcotine that its salts are decomposed, to some extent, by such compounds as ether and "benzine," so that by simply rubbing up the dry salts with one of these solvents, an amount of the alkaloid is dissolved out. Having regard to all these facts, and to what is known otherwise of narcotine and of opium, we are led to the conclusion that narcotine is undoubtedly an alkaloid, that it readily forms salts, and that it exists in opium as meconate (at least for the most part). It is no uncommon occurrence for alkaloidal salts to crystallize with varying proportions of combined water according to circumstances. I have observed this in the case of narcotine hydrochloride, one sample giving numbers indicating three molecules of water. According to Beckett and Wright, the hydrochloride of narcotine forms a series of basic salts by successive crystallizations from hot water. Their experiments I have not repeated, but the muriate certainly stands one recrystallization without decomposition.

Gmelin* states, on the authority of Bouchardat, that the molecular rotatory power of narcotine is $-130{\cdot}6°$ or $-151{\cdot}4°$ for the red ray, but that it is not ascertainable with exactness on account of the slight solubility of the alkaloid in alcohol and ether. "On addition of acids it acquires a rotatory power towards the right, the original rotatory power being brought back by neutralization with ammonia." The rotatory power of acid solutions of narcotine was found by Bouchardat to vary according to the quantity and nature of the acid. More recently Hesse has determined the specific rotatory power of narcotine with the following results†:—

		Alcohol.	Chloroform and alcohol.	Chloroform.
C	=	0·74	2	2 and 5
$[\alpha]_D$	=	−185·0	−191·5	−207·3

It may be thought that these numbers do not agree very well, but it is now understood that the "specific rotatory power" may vary according to the nature and proportion of the solvent used; even although that solvent has no action by itself on polarized light. All that we obtain in such cases is an apparent rotatory power which may differ widely from that of the pure substance. It is, therefore, necessary to state the solvent and the percentage of substance dissolved therein, as the angle of rotation does not vary directly as the amount of substance, when the latter is in solution.

Before knowing of Hesse's work on the subject, I determined the specific rotatory power of narcotine dissolved in "benzine," the solution containing 1·59 per cent. My friend Mr. W. Peddie, Assistant to the Professor of Natural Philosophy in the University, kindly made a duplicate determination for me, he using a Duboscq's polariscope with compensator, and I using a Jellet. Our results are practically identical and give the value $[\alpha]_D = -229°$. It was, of course, ascertained in the first place that the benzine did not affect appreciably the polarized light. I can confirm Bouchardat's observation that acids change the polarization from left to right, a solution of narcotine in dilute oxalic acid giving $[\alpha]_D = +62$.

PREPARATION OF GALAZYME OR ARTIFICIAL KOUMISS.*

BY ADAM GIBSON.

Much has been written regarding this medico-dietetic preparation, and having personally had some experience in the manufacture of it during the past few years, I have had opportunity of testing the various methods which have been proposed for its production.

It may be explained at the outset that the koumiss of the Tartars is prepared from mare's milk, fermentation being set up at the beginning of the season with kefir (dried koumiss of the preceding year), and, subsequently, its manufacture is effected with koumiss of a previous operation, fermentation being in all cases accelerated by agitation in a sheepskin bag.

It is unnecessary to notice here the physiological effects of the preparation, it being sufficient to state that medical practitioners have found it a valuable aid in the treatment of many wasting diseases.

The difficulty of obtaining mare's milk in this and other countries has led to experiments with other milks, and it has been found that cow's milk with some little adaptation sufficiently meets the requirements of the case. Koumiss prepared from this source has been termed "galazyme."

Various processes have been proposed, and the following classification contains the principal of them:—

1. Fresh cow's milk, containing added cane sugar, fermented with yeast or old koumiss.
2. Skimmed cow's milk, containing added cane sugar, fermented with yeast or old koumiss.
3. Skimmed and fresh cow's milk, containing added cane and milk sugars, fermented with yeast or old koumiss.

Before stating the results of my experience of these general methods, I may state that the objects aimed at are (1) formation of alcohol, carbonic and lactic acids, and (2) a preparation of homogeneous consistency.

In the first method, vinous fermentation proceeds so rapidly, with formation of acetic acid and subsequent curdling of the caseine, that the product is practically useless. Butyric fermentation also sets in after a few days, the accompanying odour entirely precluding the use of the preparation, this being due

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, January 16, 1884.

to the large amount of fat present in the fresh cow's milk.

In the second method the same objectionable curdling of caseine takes place and alcohol is produced in too large a quantity (I have found as much as 3 per cent., on the twelfth day). The product remains, no doubt, longer free from curd and there is less tendency to butyric fermentation, but on the whole the method does not give satisfactory results.

It would, therefore, appear that the use of fresh cow's milk fails to yield a satisfactory preparation, and that the use of cane sugar alone tends to defeat the objects in view. Coagulation or curdling of the caseine is certainly the principal difficulty to overcome, and to obviate this, it has been proposed to churn the mixture at hourly intervals for ten or fifteen minutes at a time during the course of twenty-four hours before bottling. It is claimed for this method that minute division of the caseine is assured. I have found that it certainly accomplishes this object, but the product is butter-milk and not galazyme, owing to the destruction of the ferment by long churning, so that the adoption of the long-continued agitation-process cannot be considered at all suitable.

The plan which I have found most practicable is to use skimmed milk, starting the fermentation with a small proportion of cane sugar, and subsequently adding a larger proportion of milk sugar according to the details which I give further on. Skimmed milk may appear to be objectionable on account of its poorer quality, but the following analysis by Hartier of mare's milk compared with an average analysis of cow's milk shows that the latter contains more caseine and fat, and less sugar than the former.

	Mare's milk.	Cow's milk.
Caseine and nitrogenous substances	1·4 per cent.	4·3 per cent.
Fat	2·1 per cent.	3·8 per cent.
Lactose	7·3 per cent.	4·5 per cent.

In using skimmed cow's milk we get rid of a quantity of fatty matter which tends under certain circumstances to favour butyric fermentation; by diluting with water we may reduce the proportion of caseine, and by adding sugar we increase the saccharine constituent, thus bringing the composition of the fluid to nearly that of mare's milk. The fatty constituent in the product is undoubtedly in less proportion than in koumiss;* but it is believed by authorities that this is not an objectionable feature, and, as will afterwards be shown, the product prepared as I propose compares very favourably with galazyme supplied to pharmacists in this country.

Formula and method of procedure :—

Take of—

Skimmed cow's milk	150 ounces.
Water	50 ,,
Brewer's yeast	1 ounce.
Cane sugar	3 ounces.
Milk sugar	5 ,,

Dissolve the cane sugar in 20 ounces of water, mix it with 75 ounces of the milk, and add the yeast; the mixture is now to be well stirred and set aside in a warm place (temperature 75° to 80 F.) for nearly six hours or until small bubbles appear on the surface of the liquid; the remaining 75 ounces of milk along with the 30 ounces of water (in which the milk sugar has been dissolved) should now be added to the fermenting milk and the whole thoroughly mixed up, strained and bottled, the corks being well tied down. It should then be kept at a temperature below 55° F. if not required for early use, or if so required it may be ripened in two or three days by keeping it at 70° F.

This method yields a preparation of a perfectly homogeneous consistency, having a sweet and acidulous taste up till the fifteenth day, after which it acquires to a slight degree the taste of butter-milk, which flavour gradually increases as it grows older. It also begins to thicken after the fifteenth day, but even at the thirtieth day the caseine remains finely divided after shaking.

It seemed to me to be of some importance to determine the composition of the galazyme so prepared, before contributing this communication, and several analyses were accordingly made at different stages.

A quantity was prepared on November 10, 1883, and a number of bottles each containing 250 c.c. were reserved for analysis.

In determining the percentage of the constituents the following methods were adopted.

For Alcohol.—250 c.c. of galazyme were submitted to distillation. The first 100 c.c. which distilled were found to contain all the alcohol present, and this quantity was diluted with distilled water to 250 c.c. and the percentage of alcohol calculated from its specific gravity.

Total solids and other milk constituents were determined by Wanklyn's methods, briefly given as follows:—

Total Solids.—5·430 grams contained in a platinum dish were evaporated to dryness on a water-bath (time taken three hours), then cooled and weighed.

For Ash.—The total solids were simply ignited, cooled and weighed.

For Fat, Caseine, Lactose and Lactic Acid.—13·181 grams were evaporated on a water-bath (time taken one hour), and the residue obtained moistened with a little alcohol, then boiled with successive portions of ether; the washings filtered, evaporated and weighed, indicated the fat present.

For Caseine.—The residue from the fat determination was digested and repeatedly washed with alcohol, then with alcohol to which a few drops of boiling water had been added, the whole being thrown on a filter and further washed with alcohol; the residue being dried as usual and weighed, it was ignited, cooled and weighed, and the ash subtracted from the amount of caseine found.

For Lactose and Lactic Acid.—The washings from the caseine residue were evaporated to dryness, ignited and weighed as in caseine, lactic acid being separately determined with normal sodium carbonate solution, 100 c.c. of galazyme being used for this purpose.

In determining carbonic acid, the gas from 250 c.c was passed into ammonia solution, which was then treated with calcium chloride solution and boiled, the precipitated calcium carbonate collected on a paper filter and carefully washed with boiling water. The filter and precipitate were afterwards trans

* According to Hartier, koumiss (*i.e.*, from mare's milk) has the following composition:—

Alcohol	1·65 per cent.
Fat	2·05 ,,
Milk sugar	2·20 ,,
Lactic acid	1·15 ,,
Caseine and albumen	1·12 ,,
Ash or salts	0·28 ,,
Carbonic acid	0·785 ,,

erred to a beaker and treated with a known volume of normal nitric acid, excess of the latter being finally determined with normal sodium carbonate solution. The amount of calcium carbonate found indicated carbonic acid present.

The following table indicates results of analyses according to these methods, and specific gravities at the different stages. It may be noted that the specific gravity at the time of bottling was 1·040 at 60° F.

Table showing Composition of Galazyme on November 14, 18 and 22

Constituents.	4th day, sp. gr. 1·0386.	8th day, sp. gr. 1·0382.	12th day, sp. gr. 1·038.
Water	88·66	88·52	88·36
Alcohol	0·60	0·80	1·00
Carbonic acid . .	0·44	0·52	0·59
Total solids . .	10·30	10·16	10·05
	100·00	100·00	100·00
Solids consisting of—			
Lactose . .	6·185	5·974	5·688
Lactic acid .	0·225	0·360	0·540
Caseine . .	2·693	2·670	2·655
Fat	0·455	0·447	0·440
Ash	0·552	0·534	0·521
Loss. . . .	0·190	0·175	0·206
	10·300	10·160	10·050

In comparison with these results, I may quote the following analysis by Wanklyn of full koumiss, forty-eight hours old, prepared in London:—

Sp. gr. 1·032 at 67°F.		Total Solids contained.	
Water	87·32	Caseine	2·84
Alcohol	1·00	Lactose and lactic acid	6·60
Carbonic acid . .	0·90	Fat	0·68
Solids	10·78	Ash	0·66
	100·00		10·78

It would appear from this comparison that the variation is no greater than we would expect to find in working with different samples of milk.

In entering so much into detail, my intention has been to show that a good artificial koumiss, equal to that found in the market, can be prepared in the pharmacist's own laboratory; and knowing the difficulty which the provincial pharmacist has in supplying a rather erratic demand for the article, I believe it is as well that we should be able to make a supply when a medical practitioner indicates his intention of using it in his practice.

[*The discussion on this paper is printed at p.* 593.]

SOME AFRICAN KOLAS,

In their Botanical, Chemical and Therapeutical Aspects.*

BY E. HECKEL AND F. SCHLAGDENHAUFFEN.

Among the vegetable products of the African soil, there is perhaps none more interesting and valuable than those which under the various names of "kola," "gourou," "ombéné," "nangoué," and "kokkorokou," are used as articles of consumption throughout tropical and equatorial Africa, as equivalent to tea, coffee, maté and cocoa. Used under the form of seeds, probably from time immemorial, by the native tribes, these products are of varying botanic origin, and their history has been up to the present time imperfectly known; but the authors have been able to avail themselves of the observations of some recent travellers to clear up some obscure points.

The products which are included by the authors under the name "kola" (the various synonyms quoted being special to particular countries) consist of seeds, yielded by two families of plants and differing very much in appearance. The kind most widely distributed, the "true kola," which by some of the natives is called the "female kola," comes from the Sterculiaceæ; another variety, called by the author "false kola," is known among the negroes as simply "kola," or "male kola." Before the authors' researches only the "true" or "female" kola was known, and it had been ascertained to be yielded by the *Sterculia acuminata*, P. de Beauv. (*Cola acuminata*, R. Br.). To this Messrs. Heckel and Schlagdenhauffen are able now to add information concerning the "male" kola, hitherto unknown, and to give reasons for believing that various other species of *Sterculia*, besides *S. acuminata*, yield kola seeds.

Dealing first with "female" kola, the authors describe at length *Sterculia acuminata* from specimens, the description agreeing with Oliver's description of var. *a* (Fl. Trop. Af., i., 220). According to the best information, the tree—which is from 30 to 60 feet high, and in general aspect resembles the chestnut—grows wild upon the western coast of Africa comprised between Sierra Leone and the Congo or Lower Guinea, reaching into the interior about five or six hundred miles, where it appears to follow the limits of the palm. Upon the eastern coast it appears to be unknown in places where it has not been introduced by the English. Dr. Schweinfurth, speaking of the country of the Nyams-Nyams, near lake Nyanza, says that among the imposing forms of vegetation a *Sterculia* of the kola kind predominates and is called locally "kokkorokou." In the country of the Momboutous (24° E. long., 3° N. lat.), too, upon asking for kola he was supplied with the fruit in its rose-coloured envelope; but the only information he could obtain there concerning it was that the nuts were found in the country in the wild state and were called "nangoué" by the natives, who chewed slices of it whilst smoking. Karsten, in his 'Flore de Colombie,' describes the plant as growing wild in the moist hot woods near the southern coast of Venezuela, but the authors believe it was probably introduced there about the same time as it was introduced into Martinique, and that it was sown by African negroes, who brought it into those countries in the same manner as they are known to have introduced *S. cordifolia* for the sake of its delicious fruit. It has also been introduced successfully by the English into the East Indies, the Seychelles, Ceylon, Demerara, Dominica, Mauritius, Sydney and Zanzibar, and by the French recently at Guadeloupe, Cayenne, Cochin China and the Gaboon. In all these stations the kola tree flourishes best in moist lands at the sea-level, or a little above. At Sierra Leone some fine trees are found at an elevation of 200 or 300 metres, but not higher than that.

The kola tree commences to yield a crop about its fourth or fifth year, but it is not until about its tenth year that it is in full bearing. A single tree will then yield an average of 120 lbs. of seed annually. The flowering is nearly continuous after the tree reaches maturity, so that a large tree bears flowers and fruit at the same time. There are two collections; the June flowering yielding the fruit in October and November and that of November and December in May and June. When the fruit is ripe it takes a browish yellow colour. In this condition dehiscence of the capsule commences along the ventral suture, exposing red and white seeds in the same shell. It is at this period that they are gathered. It has been stated that there exist two varieties of kola, one yielding exclusively red seeds and

* Abstract of a lengthy memoir read before the Union Scientifique des Pharmaciens de France (*Journ. Pharm. et de Chimie*, [5], vii., p. 553; viii., 81, 177.

the other white; but the authors have been repeatedly assured that this is not the case, and that one and the same capsule may contain fifteen seeds varying considerably in size, white and red together, without the white being considered less ripe than the red. The carpels are from 6 to 9 centimetres long and 3 to 5 thick and the spongy pericarp is about 2 or 3 millimetres thick. As many as five or six ripe carpels may result from a single flower, and these may each contain from five to fifteen seeds; but sometimes carpels are met with containing only a single seed. The seeds removed from their envelope weigh, according to their development, from 5 to 25 or 28 grams. The epiderm is the principal site of the colouring matter, and beneath it the cotyledonary tissue consists of a mass of cells gorged with large starch granules comparable to potato starch. It is in these that the alkaloids caffeine and theobromine are found in the free state.

The collection is conducted with great care and is made by women. The seeds are removed from the husk and freed from the episperm. In order to maintain their value among the negroes it is necessary to keep them in a fit state and in good condition. They are, therefore, carefully picked over, all damaged and worm-eaten seeds being removed, and the sound seeds are then placed in large baskets, made of bark and lined with "bal" leaves (*Sterculia acuminata*, Car., or *S. heterophylla*, Beauv.?); the seeds are heaped up and then covered over with more "bal" leaves which, by their thickness, resistance and dimensions, contribute not a little to the preservation of the seeds by keeping them from contact with dry air. Packed in this manner the seeds can be transported considerable distances, remaining free from mould for about a month, during which time it is not necessary to submit them to any treatment in order to preserve them fresh beyond keeping the "bal" leaves moist. But if it be desired to keep them beyond that time the operations of picking and re-packing have to be repeated about every thirty days; the seeds being washed in fresh water and fresh "bal" leaves placed in the baskets. The baskets usually contain about 3 cwts. of seeds. It is in this condition that "kola" is sent into Gambia and Goree, where the principal dealings in the seeds are carried on. In Gambia they are sold in the fresh state to merchants travelling with caravans into the interior, who dry them in the sun and reduce them to a fine powder, which is used, mixed with milk and honey, by the tribes of the interior to make a very agreeable, stimulating and nourishing beverage. It most frequently arrives at Sokota and Kouka in the Soudan and Timbuctoo, where large sales of the seeds are made, in the fresh condition; from the Soudan markets it is carried by caravans to Tripoli, and from Timbuctoo into Morocco. As might be expected the value of the kola increases as it makes its way into the interior of Africa, and the authors state that some of the tribes furthest removed from the sea pay for the dry powder with an equal weight of gold dust.

Kola plays an important part in the social life of many of the African tribes, and the authors mention some of the occasions upon which it is used in terms almost identical with those in a paper read at an evening meeting of the Pharmaceutical Society eighteen years ago (*Pharm. Journ.*, [2], vi., 450). An interchange of white kola between two chiefs is indicative of friendship and peace, whilst the sending of red kola is an act of defiance. An offer of marriage is accompanied by a present of white kola for the mother of the lady; the return of white kola is equivalent to acceptance of the suit, whilst red means rejection. The absence of a supply of kola from among the marriage presents would endanger the whole arrangement. All the oaths are administered in the presence of kola seeds; the negro stretches out his hand over them whilst he swears and eats them afterwards.

Fresh kola is used as a masticatory, as is also the dried powder, by the tribes in the interior. When fresh the taste of the seeds is first sweet, then astringent and finally bitter. When the seeds become dry the bitterness diminishes, giving place to a sweeter flavour; but upon steeping them in water for a couple of days the original bitterness is nearly restored. Preference is given for mastication to seeds containing only two cotyledonary segments, it being asserted that they are less rough than those with four to six segments; but the authors did not find anything in their chemical examination to explain this preference. The practice of kola mastication, which is always accompanied by the swallowing of the saliva, does not injuriously affect the teeth, as is the case with the betel nut, but tends to render the gums firm and exercises a tonic influence on the digestive organs. The seeds are reputed to clarify and render healthy the most foul waters, and to render tainted meat edible, and when chewed, either fresh or as a dry powder, and the saliva swallowed, to be a sure preventive against dysentery. They are also said, like *Erythroxylon Coca*, to possess the physiological property of enabling persons eating them to undergo prolonged exertion without fatigue, which is probably to be attributed to the caffeine they contain. Further it is said that kola exercises a favourable influence upon the liver, and that white people, living in those regions, who chew a small quantity before meals escape constitutional changes due to affections of that organ. They are also believed by the negroes to have aphrodisiac properties. With respect to the assertion that the pulp or powder of the seeds thrown into foul water has the property of cleaning it, an experiment made by the authors would appear to show that any action in this direction would be due to the formation of a kind of mucilage, which would act mechanically like the white of egg.

It has been pointed out that the name "kola" is applied in Africa indifferently to several Sterculaceous seeds other than those of the two varieties of *Cola acuminata*, although these are the most valued in the native markets. It is probable that the African plants capable of yielding seeds resembling the true kola are *Cola Duparquetiana*, Baill., *C. ficifolia*, Mast., *C. heterophylla*, Mast., *C. cordifolia*, Cax., and perhaps *Sterculia tomentosa*, Hend. But the authors think it doubtful whether these seeds contain caffeine, otherwise they would be as much sought after as the true kola.

In order to determine chemically the composition of kola seeds, the authors made a large number of experiments; the details fill many pages in the original paper. The dry seeds were first operated upon, and the process which appeared to give the best results was to exhaust the dried powder successively with chloroform and alcohol. The chloroform percolate was a yellowish liquid; this was evaporated to dryness, and the residue treated with water, which separated a fatty substance with an odour recalling that of cacao butter and entirely saponifiable by caustic potash. The yellow liquid upon concentration after filtration, deposited silky needles of caffeine, but when the solution was rapidly evaporated and the residue treated with water, ether or chloroform it no longer completely dissolved without using a considerable quantity and boiling, and upon such a solution cooling a small quantity of a compound crystallized out in microscopic prisms and octahedra which proved to be theobromine. The substances separated by chloroform from the dry nuts, were—caffeine, 2·348 per cent.; theobromine, 0·023 per cent.; tannin, 0·027 per cent.; fat, 0·583 per cent.

The kola powder was then dried and exhausted with alcohol. A mahogany coloured extract was obtained which when treated with boiling water dissolved entirely, but the solution on cooling deposited a large quantity of colouring matter. The aqueous solution was precipitated with triplumbic acetate, the precipitate decomposed with sulphuretted hydrogen, and a liquid obtained, free from bitterness, containing a considerable quantity of a tannin giving an intense green colour with persalts of iron, and a soluble colouring matter that formed lakes in contact with metallic solutions; the residue of the aqueous solution, after removal of excess of lead, was found to contain only glucose and a small quantity of fixed salts. The colouring matter deposited upon the cooling of the boiling water used in dissolving the alcoholic extract differed in its nature from the soluble colouring matter. It appeared to be an oxidation product from the tannin and presented considerable analogy to cinchona red; in order to distinguish it, therefore, the authors have named it "kola red."

The composition of the alcoholic extract from the dry nuts (5·826 per cent.) was found to be—tannin, 1·591 per cent.; kola red, 1·290 per cent.; glucose, 2·875 per cent.; fixed salts 0·070 per cent.

The entire composition of the kola nut is compared by the authors with that of tea, coffee and cacao as follows:

	Cacao (Mitscherlich).	Coffee (Payen).	Tea Green (Peligot).	Tea Black (Peligot).	Kola (Authors').
Fat	53 00	13·00	0·28	—	0·585

Water	6·00	12·00	—	—	11·909
	100·00	100·00	100·00	100·00	100·00

These results, it is pointed out, differ somewhat from those obtained by Attfield (*Pharm. Journ.*, [2], vi., 457), especially in the recognition of the presence of a second alkaloid and of tannin. The proportion of caffeine is higher than that observed in any coffee or, except in rare instances, in tea, and exceeds that of theobromine in cacao. The alkaloid exists in kola, as in tea, uncombined, but in coffee, according to Payen, it is present as chlorogenate of potassium and caffeine. It is worth mentioning that the authors report the presence of a considerable proportion of caffeine and some theobromine in the pericarp, but the material at their disposal was too scanty for an exhaustive investigation in this direction. The leaves, wood and bark were also examined for alkaloid, but gave negative results. As in the case of coffee, kola undergoes a considerable loss of caffeine (three-fourths) during roasting, while the quantity of essential oil present is augmented.

Some experiments have been made with this kind of kola in the treatment of the atonic diarrhœa to which Europeans are frequently liable in tropical countries. The results have been fairly satisfactory, and through the efforts of M. Heckel the medicine has been supplied to some French colonial stations for a systematic trial. The preparations used are an aqueous extract, an alcoholic extract and a wine. The alcoholic extract is made by exhausting fresh kola with 5 parts of 60° alcohol and the wine by macerating the same proportions of kola in a sweet white wine during a fortnight. Neither of these preparations, however, completely exhaust the kola, at last as far as the caffeine is concerned. The preparation of an aqueous extract presents considerable difficulty in consequence of the quantity of starch, which forms an unmanageable magma.

Concerning the "male kola" or "kola bitter," as before stated, nothing definite was known, and as recently as the year 1882 it was referred erroneously to a species of *Sterculia*. In the 'Flora of Tropical Africa' Oliver says: "The kola-bitter of Fernando-Po is the product of trees belonging to the Guttiferæ." The authors were led by this remark to attempt to obtain from various parts of the eastern coast specimens of the plant yielding "kola bitter," and although the flowers did not reach them they received specimens of the branches, leaves and fruits, together with a sufficient quantity of seeds to allow of a complete analysis being made. All the specimens received from various places corresponded in their characters, and showed that the kola bitter is the produce of a single Guttiferous species and not of several. From the material at their disposal the authors refer it to a new species, *Garcinia Kola*, Heckel. The plant is described as a tree of variable aspect, 10 to 20 feet in height, bearing towards the base of the branches large opposite leaves (12 in. long by 7 in. broad), with short petioles, whilst at the extremity of the branches the leaves are much smaller (5 in. by 2 in.). The leaves are oval, slightly dilated at the base, mucronate at the apex, without stipules, full green on the upper surface and greyish underneath. The fruit is a berry the size of an apple, with a rugose epiderm covered entirely with rough hairs. It presents three or four divisions, each containing a large oval cuneiform seed, rounded on the external and angular on the internal face; the seeds are covered with an abundant sourish yellowish pulp, constituting a true arillus. The fruit has at the base the persistent calyx still adherent to the peduncle, and sometimes the persistent corolla, and at the apex the persistent stigma. The plant is reported to occur all along the eastern coast of Africa and of Senegal, intermixed with the *Sterculia acuminata*, flourishing under the same conditions, but less widely distributed. In its known characters the plant would appear to be closely allied with *Garcinia Morella*, which, however, is essentially an Asiatic species. The seeds present one convex and two plane surfaces, the former being towards the circumference of the fruit. They are covered by an apricot-yellow episperm, below which is a large yellowish-white macropodous embryo, devoid of cotyledons, and with numerous depressions on its surface. The tissue is denser and closer than that of true kola and crackles under the teeth; it consists of a compact mass of very homogeneous cellular tissue, interspersed here and there with laticiferous vessels of varying size containing resin, the cells constituting which are filled with starch granules larger than those occurring in true kola.

Upon chewing these seeds a strongly bitter, astringent and yet aromatic taste is perceptible, which is quite different from that of true kola, and approaches in its aromatic flavour that of green coffee; it is this aromatic flavour that is esteemed by the negroes. It is worthy of remark that although the use of these seeds does not produce any notable stimulant effects or ward off fatigue, they are as much sought after and fetch nearly as high a price on the eastern coast as the true kola. In the interior, however, they are unknown. The authors are of opinion that these seeds owe their properties to the resin they contain, which is slightly stimulant. By the negroes they are thought to exercise an aphrodisiac action, which the authors consider doubtful, and as a masticatory, they are said to be a valuable remedy for colds.

An examination of fresh male kola nuts for caffeine gave negative results, the chloroform, ether and alcoholic percolates being all free from alkaloid. Besides colouring matter, tannin and glucose, two resins were separated. One of these was brown, hygrometric and soluble in ether and melted at the temperature of the water-bath; the other was yellowish-white, soluble in ether, alcohol, acetone and acetic acid, insoluble in carbon bisulphide or petroleum spirit, and had a high melting point.

A large proportion of the paper is devoted to a study of the constitution of caffeine and several of its derivatives, in reference to the identification of the alkaloidal substances obtained by the authors from the female kola.

MARSALA WINE.*

The English were the first to establish factories in Sicily for the making of the wine known by the name of Marsala. Wine of that sort was indeed made in the country previously; but it was not appreciated in foreign countries until it began to be prepared by the English, who took care to choose the best grapes for the purpose, which are those known in the country under the names of "cateratti" and "trebbiano," and which grow principally in the districts of Castelvetrano, Campobello, and Mazzara, situated in the south-western part of the island. These qualities of grapes, and more particularly the first mentioned, are rich in saccharine matter, tender-skinned, and juicy.

To secure the choicest fruit the English manufacturers make contracts with growers and advance them money, to be returned in fruit, or must of a superior quality. They reserve to themselves the right of inspecting the vines and seeing that they are properly attended to, and they fix the date of the vintage, which usually takes place in that part of the island towards the latter end of September, never earlier. If the crop is an abundant one the manufacturers willingly accept whatever may have been produced over and above the contracted quantity at the market price. On the other hand, if the crop is a poor one, they do not insist on getting the full amount of fruit they ought to receive, which would force the growers to procure the deficit at ruinous prices from other sources, but they agree to receive their due the following year. As the quality of the crop cannot be ascertained in advance, the growers, having full confidence in the honesty and uprightness of the manufacturers, accept the rates fixed by the latter, and it is in the interest of the manufacturers to act loyally towards the growers. Under no circumstance do the English manufacturers allow bad fruit to be pressed for their use, nor will they accept must that does not contain the required quantity of alcohol-producing matter.

The labours of the vintage having been brought to a close those of the factory begin; that is, the choice and trial of the wine. When the new wine is brought in it is placed in casks of about 12 hectolitres. For the English market Marsala wine requires to be highly alcoholized, so as to be able to stand the voyage and to keep. This is not necessary for the Italian market, hence the necessity of choosing the strong wines for the former. Alcohol is added to wine made for exportation, both after racking and at the time of exportation, increasing its volume by 7 per cent. The strength of the Italian wines is from 16° to 18°, while that for the English market comes to 20° and 22°. The alcohol is produced from the inferior qualities of wine, but latterly, owing to the heavy taxes levied upon spirits manufactured in Italy, other means have been resorted to to replace alcohol or to produce it naturally. With this object in view the must is boiled until its volume is reduced by two-thirds, and it is then added to new wine in lieu of alcohol. At first the manufacturers added this cooked wine at the first racking, but they found that the results were not good, so they altered their practice, and they now add it to the new wine as it is being casked, in the proportion of from 5 to 10 per cent. It is well to add the cooked wine before the must begins to ferment, as then the whole mixes up well and produces a stronger wine; after this it is allowed to clarify. A couple of months prior to casking a preliminary trial is made, which consists in examining each cask to see if the wine has the required qualities of the well-known Marsala: those that have not are marked and put aside for distilling; those of doubtful quality are set apart for further trial.

Great experience is required to appreciate the quality of the wine contained in each cask by sight, smell and taste.

Towards the end of March and the beginning of April a further trial is made on the wines put aside as doubtful. Then the racking begins, the wine being put into casks containing about 12 hectolitres. If any wine is not up to the mark it is alcoholized, and is put by for the rest of the season. In the English manufactories pumps and tubes are not used, as they prefer pouring the wine into cans, so that it may be seen when it begins to run thick.

During the ensuing year, before the time of the vintage, a fresh trial is made, after which those wines that require it are cleared. This is done by dissolving a certain quantity of isinglass, so as to produce enough froth to cover the surface of the wine contained in the cask. This froth is poured in through the bung-hole; and with a short stick, flattened at the end, the surface of the wine is moved to and fro so as to spread the froth over the entire surface. It is then left alone, and the isinglass gradually finds its way to the bottom, carrying with it every foreign substance, and leaving the wine clear. The English manufacturers used formerly white of egg and blood to clarify their wines, but they now find it more advantageous to employ isinglass. The wine, once clarified, is drawn and put into casks, care being taken to add alcohol to those that require it. Two months after this operation the wine is subjected to a further trial, when all that is not condemned to be distilled is poured into large vats containing as much as 800 hectolitres each. Smaller ones, from 130 to 180 hectolitres, are also used; and in order to get an unvarying type of wine, care is taken never to empty these vats except when absolutely necessary for repairs, but to add the new wine to the old.

These huge vats are in the shape of two truncated cones set one against the other at the large ends. Those of average capacity are laid down on their sides, and by never emptying them, they get so impregnated with alcohol that for repairs it is not only necessary to empty them completely, but to leave them open for some time in order to get rid of the alcoholic vapours, that would be enough to kill the coopers employed if sent in too soon.

In these large vats the wine gets matured, and previous to exportation it is alcoholized according to its being for the English or the Italian market.

The making of the casks requires a few words. They are called pipes, of 400 litres, quarter casks, or octaves, according to their capacity. When made they are filled with boiling water, so as to close up all the pores of the wood, and after a month they are emptied and filled with a poor wine for two or three months, after which a better sort of wine is poured into them for the same period. When required for exportation, they are emptied and cleaned by the use of chains. When filled, they are put into an outer cask for better protection.

* From a Report on the Trade and Commerce of Palermo and Sicily by Mr. Consul Churchill.

MICROSCOPICAL CHARACTERISTICS OF VEGETABLE FIBRES.

In a paper on this subject in the *Zeitschrift für Warenkunde*, Dr. V. Berthold classifies the more important vegetable fibres, according to the action upon them of iodine and sulphuric acid, as follows:—

A. Coloured blue, violet, or green by iodine and sulphuric acid:—Flax, Chinese grass and ramie (*Boehmeria nivea*), roa (*Pipturus argenteus*), cotton, hemp, and sunn-hemp (*Crotalaria juncea*).

I. Transverse sections coloured blue or violet, but showing no yellow middle lamella; cell-cavity usually filled with a yellow mass.

a. Flax.—Transverse sections occur either isolated or a small number grouped together; the separate transverse sections are not contiguous; they are polygonal, bounded by straight lines, and have sharp edges. Lamination evident, blue or yellow cell-cavity, yellow dot. Longitudinal distortions of the striæ are indicated by darker lines, which usually cross.

b. Chinese Grass and *Ramie.*—Transverse sections isolated or a small number in a group; their connection very loose; they are polygonal or irregular, and very large. Lamination very evident; cell-cavity large and irregular, often filled with dark yellow masses; sometimes striated radially. The breadth of the fibres is very variable, in the longitudinal aspect some appear very broad; distortions evident; the ends thickly rounded.

c. Roa-fibre.—Transverse sections not many in a group, polyhedral, usually with straight or slightly curved sides and rounded edge; cell-cavity narrowly oblong, regular; contents sometimes yellow. Some transverse sections are surrounded by a thin greenish lamella, and show well-marked radial striæ or fissures, and concentric lamination; the separate lamellæ vary in depth of colour.

d. Cotton.—Transverse sections always isolated, rounded, of various forms, usually kidney-shaped; cell-cavity narrow, linear; contents usually yellow. No lamination.

II. Transverse sections blue or violet, polyhedral, rounded or irregular, always surrounded by a yellow middle lamella.

a. Hemp.—Transverse sections always in groups, contiguous, with rounded edge, surrounded by a thin yellow middle lamella, beautifully laminated concentrically; cell-cavity linear, simple or branched, irregular, sometimes broad, without contents.

b. Sunn-hemp. — Transverse sections numerous in a group, closely contiguous, resembling those of hemp, often sickle-shaped, either polyhedral or oval, with a small round cell-cavity; often with yellow contents. Surrounded by a broad yellow middle lamella, from which the inner laminæ are often detached.

B. Coloured yellow by iodine and sulphuric acid.

I. Dicotyledons. No vessels besides the bast-fibres; cell-cavity with constrictions.

1. Transverse sections in groups, polygonal, bounded by straight lines, with sharp edges; cell-cavity round or oval, smooth, empty; surrounded by a narrow middle lamella of the same colour.

a. Jute. — Cell-cavity large, roundish, oval; middle lamella very narrow; no lamination; the ends always rounded, and almost always strongly thickened.

b. Abelmoschus.—Transverse sections larger than in *a*, bounded by straight lines, sharp-edged; cell-cavity a dot or line, oval, rarely angular, smaller than in *a*. Fibres of uniform thickness, ends broad, rounded, often thickened; cell-cavity variable, often reduced to a line.

2. Transverse sections always in groups, polygonal, bounded by straight lines, with sharp or slightly rounded edges; cell-cavity empty. Middle lamella broad and decidedly darker than the transverse section; cell-cavity with constrictions, locally entirely absent.

a. Hibiscus.—Edges sharp or rounded; in the first case the cell-cavity small, in the latter case broader and oval; middle lamella sometimes wanting; transverse sections only slightly and inconspicuously laminated. Fibres of very various thickness, not usually striated longitudinally; ends blunt and almost always thickened.

b. Urena sinuata.—Edges sharp; cell-cavity very small, a dot or narrow short line; middle lamella broad and very distinct; transverse section not laminated. Fibres of uniform thickness, rarely striated longitudinally; ends rounded, rarely somewhat thickened.

II. Monocotyledons. Vessels in addition to bast-fibres; cell-cavity without constrictions.

1. Transverse section usually rounded, rarely polyhedral; cell-cavity always round; no middle lamella.

a. New Zealand Flax (*Phormium tenax*).—Transverse sections small, usually round, closely contiguous, polygonal, with rounded edges; cell-cavity empty. Fibres thin, uniform, smooth, rigid; cell-cavity small, of uniform breadth, without striation or distortion; ends sharp.

c. Manila Hemp. (*Musa textilis*).—Transverse sections polygonal, with rounded edges or roundish; cell-cavity large, roundish, sometimes with yellow contents. Fibres of uniform thickness, smooth, not striated, with thin walls; ends sharp or slightly rounded. After combustion of the fibre siliceous skeletons remain behind in the form of strings.

2. Transverse section evidently polygonal; cell-cavity polygonal, with one or more sharp edges, moderately large; no middle lamella.

a. African Hemp (*Senseviera*).—Transverse sections closely contiguous, not laminated. Fibres thin, smooth, with sharp ends.

b. Aloe.—Transverse sections not very numerous in a group; edges slightly rounded; cell-cavity not very large, polygonal, often with rounded ends; large spiral vessels. Fibres of uniform thickness, without structure; ends sharp or rounded.

c. Agave.—Transverse sections polygonal, bounded by straight lines, closely contiguous; cell-cavity large, polygonal; its edges less sharp. Fibres rigid, considerably broader towards the middle; ends broad, thickened, sometimes split.

3. *Yucca.*—Transverse sections polygonal, closely contiguous, small, bounded by straight lines; edges very sharp; cell-cavity small, round or linear; middle lamella very evident. Fibres narrow, striated, with sharp ends.

THE DETERMINATION OF TANNIN IN VEGETABLE CELLS.

In the 'Proceedings' of the Cambridge Philosophical Society Mr. W. Gardiner assigns reasons for objecting to all the microchemical reagents hitherto used for the detection of tannin. Iron sulphate he finds convenient when the products are blue and not green. He prefers to use a solution of ammonium molybdate in concentrated ammonium chloride; this gives with tannins a copious yellow precipitate. It can also be used for determining the presence of digallic acid, with which it produces only a red colour; the compound with gallic acid is soluble in ammonium chloride, while that with tannin is not.

The determination of tannin in tissues preserved in alcohol is facilitated by the fact that dead protoplasm gives a permanent precipitate with tannins.

The author regards tannins as secondary products of metastasis, especially when this process is very active, and thinks that they have no further use in the vegetable economy. In the old leaves of a cutting of the cherry laurel which had already put out roots and shoots, the quantity of tannin had considerably increased.

THE POSITION OF PHARMACISTS IN RELATION TO THE PHARMACOPŒIA.

The following is a complete list of the petitions, together with the number of signatures to each, presented in the House of Commons between the 18th and the 25th of August inclusive, in favour of an alteration of the Medical Bill in the direction desired by the Council of the Pharmaceutical Society:—

August 18.

Pharmaceutical chemists and chemists and druggists, Ryde (*Mr. Ashley*)	14
— West Bromwich (*Mr. Brogden*)	16
— Wednesbury (*Mr. Brogden*)	7
Medical practitioners of West Bromwich (*Mr. Brogden*)	7
Pharmaceutical chemists and chemists and druggists, Edinburgh (*Mr. Buchanan*)	27
— Edinburgh (*Mr. Buchanan*)	77
— Kirkaldy, N.B. (*Sir George Campbell*)	17
— Birmingham (*Mr. Chamberlain*)	23
— — (*Mr. Chamberlain*)	42
— Chiswick and other places (*Sir Charles Dilke*)	30

F. M. Rimmington and others (*Mr. Forster*)	23
Pharmaceutical chemists and chemists and druggists, Cambridge (*Mr. William Fowler*)	18
— Clifton and other places (*Mr. Lewis Fry*)	70
— Southampton (*Mr. Giles*)	14
— City of Worcester (*Mr. Rowley Hill*)	20
— Taunton (*Sir Henry James*)	12
Hamilton Kinglake, M.D., Taunton (*Sir Henry James*)	1
Medical practitioners of Penrith and Appleby (*Mr. William Lowther*)	13
Pharmaceutical chemists and chemists and druggists in London and other places (*Sir William M'Arthur*)	22
— Grantham (*Mr. Mellor*)	16
— High Wycombe (*Lieut.-Col. Gerard Smith*)	7
— Newton, Monmouth (*Mr. Hanbury-Tracy*)	6
— Selkirk and other places (*Mr. Trevelyan*)	10
— Liverpool (*Mr. Whitley*)	56
— — (*Mr. Whitley*)	94
— — (*Mr. Whitley*)	80

August 20.

Pharmaceutical chemists and chemists and druggists, Fenton, and other places (*Mr. Broadhurst*)	21
— Dunfermline (*Mr. Campbell-Bannerman*)	6
— Colchester (*Mr. Causton*)	9
— Maldon (*Mr. Courtauld*)	5
— James Hart, and others (*Mr. Cross*)	24
— Neath (*Mr. Dillwyn*)	7
— Aberdeen (*Dr. Farquharson*)	17
— Dumfries (*Dr. Farquharson*)	20
— Forfar (*Dr. Farquharson*)	3
— Inverness (*Dr. Farquharson*)	8
Medical practitioners of Axmouth and other places (*Dr. Farquharson*)	5
— Stockport (*Dr. Farquharson*)	6
Pharmaceutical chemists and chemists and druggists, Bodmin (*Mr. Leveson Gower*)	3
— Abergele (*Lord Richard Grosvenor*)	3
— Bridgnorth (*Lord Richard Grosvenor*)	4
— Carmarthen (*Lord Richard Grosvenor*)	8
— Oswestry (*Lord Richard Grosvenor*)	7
— Hyde (*Lord Richard Grosvenor*)	7
— Carnarvon (*Lord Richard Grosvenor*)	5
— R. D. Commans and others (*Sir Arthur Hayter*)	19
— Gateshead (*Sir Farrer Herschell*)	10
— Carlisle (*Sir Farrer Herschell*)	20
— North Shields (*Sir Farrer Herschell*)	17
— Whitehaven (*Sir Farrer Herschell*)	18
— Darlington (*Sir Farrer Herschell*)	17
— Morpeth (*Sir Farrer Herschell*)	2
— Hexham (*Sir Farrer Herschell*)	3
— Bishop Auckland (*Sir Farrer Herschell*)	7
— Wigton, in the county of Cumberland (*Sir Farrer Herschell*)	4
— Peckham and neighbourhood (*Sir William M'Arthur*)	18
— Barnstaple and other places (*Sir Stafford Northcote*)	22
— Lincoln (*Mr. Hinde Palmer*)	25
— Kingston-on-Thames and neighbourhood (*Sir Henry Peek*)	15
Medical practitioners of Edinburgh (*Sir Lyon Playfair*)	18
Pharmaceutical chemists and chemists and druggists of Devonport (*Mr. Puleston*)	13
— Cardiff (*Sir Edward Reed*)	30
— Maidstone (*Mr. Alexander Henry Ross*)	12
— Dudley (*Mr. Sheridan*)	9
— Stalybridge (*Mr. Summers*)	5
— Ipswich (*Mr. Thornhill*)	14
— Bury Saint Edmunds (*Mr. Thornhill*)	13
— Harwich (*Mr. Thornhill*)	4
Pharmaceutical chemists and chemists and druggists, Macclesfield (*Mr. Henry Tollemache*)	12
— Stockport (*Mr. Henry Tollemache*)	16
— Chester (*Mr. Henry Tollemache*)	25
— Tottenham and neighbourhood (*Mr. Torrens*)	10
— London (*Mr. Torrens*)	32
— — (*Mr. Torrens*)	16
— — (*Mr. Torrens*)	6

The Pharmaceutical Journal.

SATURDAY, JANUARY 26, 1884.

MATERIALS FOR SURGICAL DRESSINGS.

THE peaceful revolution which the art of surgery in so far as the treatment of wounds is concerned has undergone since Mr.—now Sir JOSEPH—LISTER first broached his views respecting septic poisoning has brought in its train a whole army of antiseptic solutions and dressings concerning which previous generations of pharmacists knew little or nothing. Some time ago several pages in this Journal were devoted to an article on the subject of antiseptic pharmacy and since then every effort has been made to keep our readers *au courant* with the literature devoted to the subject. In doing this we have had occasion to mention a number of substances that have been recommended from time to time as suitable materials for surgic al ressings, amongst them peat, moss, wood-wool, jute, oakum, absorbent cotton, etc. It has not always been evident upon what special properties the recommendation of a particular substance has been based, and probably the *raison d'être* has been usually to be found closely associated with the pecuniary interests of the promoter. ut in respect to one substance which has been recommended—sphagnum moss—it may be assumed that it is hardly open to that reproach, if reproach be, since an ample supply of it is available to any person choosing to seek for it. Moreover, it presents one advantage in that its supposed merits have been intelligently discussed in comparison with other materials in a pamphlet by Dr. H. LEISRINK.

The antiputrescent property of peat-moss has long been known, though probably the only account to which it has yet been turned by pharmacists has been in the preservation of leeches. This preservative property has been attributed to the humic and allied acids resulting from the slow oxidation of the wet cellulose, and therefore the older the peat, and consequently the further the oxidation has proceeded, the more powerful is this action found to be. But this change is accompanied by other physical alterations that affect the capability of the peat for absorbing liquids, which indeed it loses entirely after it has been once dried. Even in this condition, however, it appears to be not without its surgical uses, for Dr. NEUBER, of Kiel, says that he has found that a wound dressed with a paste made by triturating dried black peat with water to heal without formation of pus. These considerations appear to have turned the attention of Dr. MIELCK and Dr. LEISRINK to the "bog moss" which forms so important a constituent of peat, with the result that they came to the conclusion that in the widely distributed different species of *Sphagnum* the surgeon has at his command an unlimited supply of a material which from its elasticity and especially its capability of sucking up liquids,—absorbing is hardly a sufficiently strong word,—makes an unsurpassed dressing for receiving the discharge from open wounds. It does not appear, however, that the unaltered sphagnum possesses any antiseptic properties; on the other hand, it is not thought likely to set up any septic action, though for safety it may be submitted before use to the action of a jet of steam or moistened with a weak solution of corrosive sublimate. Its chief value appears to lie in its extraordinary avidity for liquids, which allows of it receiving a discharge until it has been increased to as much as eight times its original weight, without showing a sign of supersaturation. The explanation of this property is to be found in the known peculiarity of structure of the sphagnum, upon which indeed its capability of performing its very useful part in the economy of nature is dependent. According to SACHS, as the development of the young leaf progresses the cells of the veinless lamina become differentiated into large broad lozenge-shaped cells and narrow tubular cells running between and bounding them, the latter forming chlorophyll granules and constituting the functional tissue of the leaf. The larger cells, however, lose the whole of their contents, and hence appear colourless; whilst in their walls are large dots, with thickened edges, the part of the cell-wall enclosed by the dot becoming absorbed, and forming large usually circular holes. The epidermal tissue of the stem and branches also consists of from one to four layers of broad thin-walled empty cells, which in *S. cymbifolium* possess spiral thickenings and round holes similar to those of the leaves. It is these colourless cells, both of the leaf and the stem and branches, that serve as a capillary apparatus for the plant, through which the water of the bogs in which sphagnum grows is raised and carried to the upper parts, penetrating to the very summits as in a sponge, even when the tufts stand high above the water-level. The capillary action which the sphagnum exercises is therefore widely spread throughout the plant, whilst in jute and similar substances this is limited to the interstices between the individual fibres. The whole of this mechanism of imbibition is admirably explained and figured in the pamphlet 'Der Torfmoos-Verband,' to which reference has been already made.

It was not to be expected, however, that the superiority of sphagnum, even in this respect, would remain unchallenged by the advocates of rival substances. But in a number of comparative experiments, the results of which are published, sphagnum appears at least to have held its own, and quite justified Dr. LEISRINK's claim that when carefully collected, dried and made into pads or pillows, it forms a surgical dressing which, whilst extremely elastic and hence adapting itself closely to the surface to which it is applied, possesses the property of imbibing secretions to a remarkable degree. It would appear, however, that its value may be seriously affected by submitting it to too high a temperature during the operation of drying, by which indeed the structure of the moss, upon which its most characteristic property depends, is more or less extensively modified.

With commendable promptitude the Calendar of the Pharmaceutical Society of Great Britain for 1884 has been already printed and is now ready for delivery. To those who in previous years have made acquaintance with the useful volume which, under this name, the Society places annually at the disposal of chemists and druggists at a nominal sum nothing beyond the simple announcement is necessary; but it may be doing others a service to refer them to an advertisement of the Calendar that appears upon another page, from which they will see that, besides the lists of members and associates, as well as information respecting the examinations, the Benevolent Fund, and other matters more or less connected with the Society's operations, it contains a digest of a number of Acts of Parliament, Inland Revenue orders, etc., that have a bearing upon the business of a chemist and druggist.

* * *

After a delay of five months, the part of the official report on Public Petitions referring to the closing days of the last session has been delivered. On another page will be found an extract from it consisting of a list of the petitions that were presented in favour of an amendment of the late Medical Bill, in which provision should be made for the authoritative representation of pharmacists in any future committee that may be engaged in compiling a national Pharmacopœia. The total number of petitions in the list is 259, signed by 4118 petitioners, and it will be seen that among them are several proceeding from medical practitioners.

* * *

The Special Board for Medicine of the University of Cambridge has just issued, for the guidance of students proceeding to medical and surgical degrees, a Schedule defining the range of the examination in Pharmacy and Pharmaceutical Chemistry. From this it appears that the subjects that the questions will have reference to are the weights and measures of the British Pharmacopœia and of the Metric System and their mutual relations; the nature and use of the pharmaceutical processes of infusion, decoction, distillation, percolation, and solution; the chief steps in the preparation of quinine, morphine, carbolic acid, salicylic acid, hydrocyanic acid, ether, chloroform, and the chlorides of mercury; the more important impurities or adulterations which may be associated with quinine, morphine, opium, ether, chloroform, iodide of potassium, subchloride of mercury, mercury with chalk, and sulphuric acid, together with the tests by which they may be detected; the chief instances of chemical incompatibility between drugs which are in common use; the proportions of the essential ingredients contained in the pharmacopœial preparations (for internal use) of arsenic, antimony, opium, atropine, morphine, quinine, and strychnine, and the chief ingredients of the more important compound preparations; and the common or popular names of the more important drugs and preparations. The student will moreover be expected to recognize ordinary specimens of the more important crude drugs and of the more characteristic preparations.

* * *

The *Lancet*, in an editorial article, enlarges upon the mischief caused by the unrestricted traffic in patent medicines, and remarks that it says little for our national morality that in order to keep up the dignity and discharge the obligations of the State it is found necessary or expedient to resort to such a questionable measure as the levying an impost on these articles. Our contemporary is of opinion that "Her Majesty's ministers ought to stamp out at once such a crying abuse, immoral in principle and fatal in practice." Incidentally, the article illustrates the remark we made recently as to the imperfect acquaintance with the actual facts possessed, as a rule, by those who discuss the subject. After mentioning approvingly the practice in France of stating the ingredients of a proprietary medicine on the label, the writer says, "Here, in England, if a chemist ventures in open honesty to state the composition of the medicines he sells he is in danger of being accused of contravening the patents law."

* * *

The *British Medical Journal* for the 19th inst. contains an account of an outbreak of trichinosis at Emersleben, in Prussian Saxony, which vividly illustrates the danger attending the eating of pig's flesh in the uncooked condition. After the selling of the flesh of a single pig in this village in September last, 250 persons out of a population of 700 were attacked with trichinosis and 42 died. Four persons on a visit to the village were attacked on their return home, and two died, and there were also nine fatal cases in a neighbouring village where some of the flesh was sold. The flesh appeared to exercise the most fatal effects when eaten before the salt or condiments had had time to act upon the trichinæ. In one instance a servant was attacked after eating a raw sausage made from the flesh, but other members of the household who ate some of the same lot of sausages which had been plunged in boiling soup for a few minutes escaped. In another case, a man who was known to have eaten three-quarters of a pound of the raw flesh enjoyed similar immunity, but, *pace* Sir Wilfrid, he had washed it down with a quart of brandy.

* * *

The resolution passed at a meeting held during the visit of the British Medical Association to Liverpool, in July last, appears to be now taking practical shape. A provisional Committee has issued a prospectus of a Medical Sickness Annuity and Life Assurance Society, including tables of the premiums for securing the payment during sickness incapacitating from professional duty of two, three or four guineas per week; the provision of annuities commencing at the age of 65; and the assurance of sums payable at death. The draft rules are published in the current number of the *British Medical Journal*, from which it appears that membership is to be confined strictly to registered medical practitioners.

* * *

The Asclepiad is the title of a new quarterly periodical issued by Dr. B. W. Richardson, which is intended to be a "book of original research in the science, art and literature of medicine, preventive and curative." The first number opens with a paper on "Morphia Habitués and their Treatment," in which Dr. Richardson discusses the causes that usually tend to the formation of the morphia habit and the methods for its treatment. When it is desirable to attempt to break off this habit,—which, however, he does not do without taking into account the circumstances that led to its contraction,—he appears to prefer the plan of a systematic, firm and gradual withdrawal of the morphia extending over a period varying from seven to twenty-one days "unaided by any surreptitious alliances with substitutes." Nearly a third of the number is devoted to a characteristic paper entitled "Felicity as a Sanitary Research.

* * *

At a meeting of the Royal Society of Edinburgh, held on January 21, Mr. John Aitken contributed a very interesting paper on "The Effect of Heat on the Atmospheric Dust." The paper, which was illustrated by some brilliant experiments, was mostly of purely physical interest, but the following facts may be of interest to pharmacists. Mr. Aitken demonstrated that dust of all kinds is much more readily deposited on a cold than on a hot surface, and that moisture hinders the precipitation. These facts may explain why the membrane of the lungs is preserved so free from air impurities. It was also shown that a disturbed electrical condition of the atmosphere greatly favours the deposition of dust. Mr. Aitken suggests that this may be the explanation of the popular observation that milk more readily turns sour, and that other fermentive processes are more rapidly induced in thundery weather, the electrical conditions increasing the number of bacteria and other germs deposited in a given time.

* * *

In a review of the state of planting enterprise in Ceylon at the beginning of December, the *Ceylon Observer* puts forward a return of twenty-two millions as a "moderate" estimate of the number of cinchona trees two years old and upwards in the island. Our contemporary states that the quantity of bark that will be harvested depends upon the state of the home market, but that if prices improve there is no doubt an annual export of eight to ten million pounds of cinchona bark from Ceylon could be kept up for a long period to come. At the same time we learn from trustworthy sources of information here that there are signs of a very considerable falling off in the yield of bark, and that on many estates the cinchona plantations are rapidly dying out.

* * *

At the next meeting of the Chemists' Assistants' Association, to be held on Wednesday, January 30th, a paper on "Turpentine" will be read by Mr. F. H. Alcock.

* * *

The next meeting of the Manchester Pharmaceutical Association will be held at the Owens College (Medical Theatre, Coupland Street entrance), on Tuesday evening next, January 29, at 7.30 p.m., when a paper on "Cinchona Barks" will be read by Mr. William Elborne.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

EVENING MEETING.

The third meeting of the present session was held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday, January 16, at half-past eight o'clock.

Mr. John Nesbit, President of the Branch, in the chair.

The minutes of the former meeting were read and confirmed.

The following donations were laid on the table, and thanks voted to the donors:—

To the Library—

Canadian Pharmaceutical Journal, 1883.

From the ONTARIO COLLEGE OF PHARMACY.

To the Museum—

Series of specimens in illustration of a paper on "The Shale Products Industry."*

From Mr. THOMAS STEPHENSON.

The President then called upon Mr. Dott to read a paper on—

THE SALTS OF NARCOTINE.

BY DAVID BROWN DOTT, F.R.S.E.,

The paper is printed on p. 581.

The President moved a vote of thanks to Mr. Dott, which was heartily accorded, and there being no discussion, the next paper, on—

THE PREPARATION OF GALAZYME OR ARTIFICIAL KOUMISS.

BY ADAM GIBSON,

was read by Mr. MacEwan.

The paper is printed on p. 582, and gave rise to the following discussion:—

The President, in moving a vote of thanks to Mr. Gibson, said that the process which he communicated appeared to be a very practical one, and judging from the analytical results it compared most favourably with that mentioned by Mr. Wanklyn. He thought, however, that cow's milk could never yield such a koumiss as that prepared from mare's milk; because the caseins contained in them, though chemically identical, differed physically, cow's milk giving a hard, and mare's milk a soft and easily digested curd. He believed that the superiority of true Russian koumiss was due to this property of mare's milk casein. It should not be forgotten that the koumiss used in this country was only a substitute for true koumiss (which it was impossible to import from Russia) and in these circumstances Mr. Gibson's paper could not fail to be of interest and value to those who had a demand for the article.

Mr. Gilmour seconded the motion and corroborated the President's remarks on the superiority of mare's milk koumiss. His experience of koumiss as supplied in this country led him to believe that it was an unsatisfactory article to deal with. He had recently heard of a case in which the first few bottles of a supply were admirable and were appreciated, but one bottle was so bad that it caused extreme gastric irritation, from which the patient was not likely to recover. It was possible that by adopting the process which had been communicated such unhappy results might be prevented, because the retailer could always know the age of the preparation; but he thought it necessary to point out that most scrupulous care should be taken to ensure thorough cleanliness of bottles and other vessels used, otherwise fermentation might be unduly accelerated and good and bad results be obtained from one brewing.

Mr. MacEwan returned thanks on behalf of Mr.

* *Pharm. Journ.*, January 19, 1884.

Gibson. He wished to emphasize the remarks made by the President, regarding the difference between Tartar koumiss and the artificial variety; no doubt the latter could not be so readily assimilated, but it was claimed for it that during the progress of fermentation, the casein was rendered more digestible. It had occurred to him that instead of skimmed milk the first portions of milk drawn during milking might be employed. It had recently been shown that these portions contained less than 1 per cent. of fat, while the last portions contained nearly 6 per cent. If, therefore, a supply of the former could be had, he thought that it would have an advantage over skimmed milk so far as freshness was concerned.

Mr. Gilmour said that it was well known that the last portions of milk (called "afterings" by country people) were extremely rich in fatty matter, and were much used by invalids. The first portions were correspondingly weak and would, he thought, be very suitable for koumiss.

A paper was then read on—

Aqueous Mixtures containing Powdered Chlorate of Potash.

BY JOHN RUTHERFORD HILL,

Pharmaceutical Chemist.

It is a common practice to prescribe gargles, mouthwashes and mixtures containing a much larger proportion of chlorate of potash than the aqueous menstruum is capable of dissolving and the object of the following note is to point out some objections to this practice and to suggest a more excellent way.

It not unfrequently happens that such gargles, etc., are ordered to be made with boiling water, but no discreet dispenser would be so foolish as to follow the directions of the prescriber in such a case, because, although the whole of the chlorate might thereby be dissolved, it would, of course, be deposited in a crystalline form as the solution cooled.

It sometimes happens, however, that the proportion of chlorate is very near the quantity which the menstruum is understood to be capable of holding in solution at the normal temperature; and in such cases, I believe, many dispensers do not hesitate to facilitate solution by the application of heat. Even in these instances there is always a risk that separation of crystals may ensue, either from an erroneous calculation as to the degree of solubility, or from the normal temperature falling considerably below that at which the solubility estimations were made; and consequently this process is not altogether free from objection.

The least objectionable method is generally understood to be that of reducing the chlorate of potash to very fine powder, using in all cases cold water only and attaching a "shake the bottle" label.

If the chlorate remained in the condition of fine powder this might meet the first difficulty, because, though not in solution, it would be in the next best condition for application to inflamed and ulcerated surfaces. Unfortunately, however, this is not the case, and chlorate of potash gargles, etc., so dispensed soon become unfit for use, owing to the rapidity with which finely powdered chlorate resumes the crystalline condition.

My attention had been frequently directed to this circumstance by observing that when such gargles, etc., had to be repeated there were very often present, in the bottle which had previously contained them, a few pretty large crystals of chlorate of potash. A short time since the subject was again brought very forcibly under my notice in the following manner.

About twelve months ago I dispensed a gargle containing ʒiv chlorate of potash in 8 ounces of water. About one half had been used at the time and the remainder set aside until about two months ago; at which time circumstances arose calling for the use of a similar remedy. The half empty bottle was brought to me to see if the same gargle would be suitable for this case, and I found that the whole of the undissolved chlorate of potash had, in the interval, passed from a condition of fine powder to that of pretty large tabular crystals, and the gargle was therefore, in a state quite unfit for use.

It occurred to me that it might be possible to prevent the chlorate resuming the crystalline form, at least for a reasonable length of time, by adding to the gargle some substance likely to interfere with crystallization. To determine this point the following mixtures were prepared:—

No. 1. Chlorate of potash ʒj. water to ℥j.
No. 2. Chlorate of potash ʒj. glycerine ʒj. water to ℥j.
No. 3. Chlorate of potash ʒj. simple syrup ʒij. water to ℥j.
No. 4. Chlorate of potash ʒj. gum arabic gr. x. water to ℥j.
No. 5. Chlorate of potash ʒj. gum tragacanth gr. iij. water to ℥j.
No. 6. Chlorate of potash ʒj. honey ʒj. water to ℥j.
No. 7. Chlorate of potash ʒj. treacle ʒj. water to ℥j.

The chlorate of potash was in each case reduced to very fine powder, and the mixtures were all equally exposed to the variable temperature of an ordinary sitting-room.

On examining the specimens about twenty-four hours after they had been so exposed I found that in every one of them a portion of the chlorate had passed into the condition of very thin, sharp-edged tabular crystals, exhibiting in many cases the iridescent properties of thin transparent plates. The time of examination was on the morning of the second day when the temperature of the room was several degrees less than it had been in the course of the previous night; a circumstance which, I believe, has a good deal to do with the rapid change of the chlorate from a state of fine powder to that of sharp crystals.

When the temperature of the room rises a quantity of the chlorate passes into solution and is deposited in the crystalline condition as soon as the temperature falls. This accounts for the change so far as a portion of the chlorate is concerned, but does not explain how the whole becomes ultimately so altered. This, I think, is brought about in the following manner. When the temperature rises a portion of the chlorate dissolves and when the temperature falls it is deposited as crystals. On the temperature again rising a fresh portion of the powdered chlorate is dissolved, because the powder dissolves more readily than the crystals, and this second portion is in turn deposited, either as a fresh crop of crystals, or, more probably, as an addition to those already formed. In this way, with each day's variations in temperature, the process goes on until, as already stated, the whole of the chlorate takes the form of pretty large tabular crystals.

The theory that this change is at least very much accelerated by the variable temperature of an ordinary bedroom or sitting-room was confirmed in the following manner. A mixture containing 1 drachm of finely powdered chlorate in 1 ounce of water was kept for a month in a place where the temperature did not vary more than two or three degrees. At the end of that time it was found that the chlorate had passed into a state of small, somewhat granular crystals, showing only a slight tendency to form crystalline plates. In this condition, I believe, it would be less objectionable for use as a gargle than in the other case where a number of sharp-edged plates were formed; but, nevertheless, it appears that, even under the most favourable conditions, it is impossible to retain chlorate of potash in a state of fine powder in presence of water.

From what has been stated it will be apparent that none of the substances employed had the effect of preventing crystallization, and that a single day's exposure to the variable temperature of a sitting-room was sufficient to produce such an alteration of the chlorate as to render the gargle, etc., unfit for use. Treacle, tragacanth and honey seemed to have a slight influence in retarding the process of crystallization; the crystals formed in these mixtures being of somewhat smaller size. They failed, however, to accomplish the object in view, which was not simply retardation but prevention. Thus, then, we have shown that the practice of prescribing such mixtures is open to a serious objection; but there is still another clause to the indictment.

Such gargles or mixtures are frequently directed to be taken in regular specified quantities; the intention being that each quantity should contain a definite dose of chlorate. In the case of a heavy salt like chlorate of potash, however, subsidence takes place so rapidly that, even though the bottle be vigorously shaken immediately before measuring out a dose, it is practically impossible to obtain a reasonable approach to uniformity, and, therefore, the intention of the prescriber cannot be attained.

The practice to which this note is meant to call attention is then, to say the least of it, shown to be undesirable; I believe it to be also unnecessary.

It is the province of the pharmacist to carry out, with strict fidelity, the directions of the physician, and he may not presume to dictate. While this is so, however, we believe that it is not only his province but his duty to draw attention to defects in prevailing methods and to devise improvements.

Believing this to be so, I venture to suggest that the practice referred to might be advantageously departed from, and that chlorate of potash for such purposes should always be prescribed in the form of powders. The patient could be directed to add the requisite quantity of water at the time of using; there would be no risk from crystallization; and the dose would be uniform. By this means both difficulties would be completely disposed of, and it would be, in every respect, a more excellent way.

The following discussion took place:—

Mr. Gilmour asked if the bottles had been shaken during the progress of the experiments.

Mr. Hill said that he had shaken them repeatedly so as to simulate, as far as possible, the ordinary conditions.

Mr. Gilmour then said that the formation of large crystals in these circumstances was contrary to his experience, large crystals of chemicals being obtained when the solutions were at perfect rest. The subject of crystallization was at all times an interesting one, and was particularly so in cases allied to the everyday work of the pharmacist. The explanation which had been given seemed to be correct, but he might point out that although the chlorate was practically in fine powder, still, in that condition, the crystalline form was merely minimized, and the minute crystals would form points of growth. He had much pleasure in moving a vote of thanks to Mr. Hill and complimented him on the practical manner in which he had treated a subject of general interest.

Mr. Stephenson seconded the motion and remarked that he was somewhat surprised to hear of the circumstance. It was of importance that such matters should be brought under their notice, for they had a serious aspect. He had hitherto acted upon the general opinion regarding such mixtures, namely, not to use hot water, but rather to reduce the chlorate to very fine powder. Mr. Hill's experiments sufficiently proved that crystallization could not be prevented by ordinary means, and he would suggest as a way out of the difficulty, that solutions under the saturation point should be prescribed.

Mr. Dott said that Mr. Hill's explanation of the matter was correct. The powdered chlorate was undoubtedly in the same crystalline condition as the unpowdered chlorate; still the former gave a larger surface than the latter and would pass more quickly into solution on the least rise of temperature, and when the temperature decreased it would necessarily be deposited as explained.

The President conveyed the thanks of the meeting to Mr. Hill, and remarked that he could not agree with the proposal to prescribe the chlorate in powder form. Powders were not good pharmacy, because the patient required to do what the pharmacist should do, namely, bring the remedy into a state suitable for administration. Apart from that, powders led up to a demand for the medicine in bulk, and in this demand the income of the pharmacist disappeared.

Mr. Mackenzie hoped that Mr. Hill would determine the solubility of the chlorate at different temperatures. Such solubilities would be of great use at the dispensing-counter, and would form a guide to the prescriber.

Mr. Gilmour now remarked that he was under the impression that when crystallization began the crystals continued to grow even after the solution was under the saturation point.

The President said that he also had that idea, and had seen it stated in some text-books that in the crystallization of carbonate of soda the mother liquor was not a saturated solution of carbonate.

Mr. MacEwan: Perhaps the mother liquor contained caustic soda, which would prevent the full proportion of carbonate remaining in solution.

The President, continuing, said that he thought the case referred to was that of recrystallization. Some time ago Mr. Dott, in a paper on Salicin, had stated that the mother liquor was always a saturated solution. Perhaps he might give his reasons for that statement.

Mr. Dott said that there was not the least ground for stating that crystallization would proceed indefinitely. Provided the temperature and volume were constant and the solution in presence of the deposited crystals, the solution would necessarily remain at the saturation point.

Mr. Hill then said that the interesting discussion which had arisen from his paper was a sufficient reward for any little trouble he had taken in the matter. He explained that it was the intention of the prescriber to order excess of the chlorate, and his suggestion was based on that fact. It had occurred to him that a determination of solubilities would be useful, and he would keep it in view, but there were certain circumstances which would negative the results in such cases as that under notice; thus tinctures (particularly tr. ferri perchlor.) were often prescribed along with the chlorate, so that the solvent power of the vehicle was diminished thereby. He might state that the solubility given by Squire (an authority often consulted by pharmacists) was 1 in 12, while Attfield gave it as 1 in 16. The latter was the better basis to work upon, but even that proportion is dangerous, seeing that it is so at 60° F., a temperature which is not at all constant.

Before the meeting adjourned, the President called attention to a herbarium exhibited by Mr. Thomas Stephenson, and for which he had been awarded a bronze medal by the Council of the Society. He hoped that other apprentices would turn their attention to field botany and form collections for the annual competition. The Society had other honours open to young pharmacists, particularly the Jacob Bell Scholarships, which, apart from their mere pecuniary value, gave their holders opportunity for advancement which could scarcely be obtained by other means. For these Scotchmen had equal rights with their friends on the other side of Tweed, and he hoped that some would ere long be successful in this competition.

Provincial Transactions.

ANNUAL DINNER OF THE NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

Last week about sixty members of the above Society dined together at the George Hotel, under the Presidency of Mr. Councillor Fitzhugh, F.C.S., the vice-chairs being occupied by Mr. J. Wilford and Mr. T. B. Fletcher.

The Hon. Secretary (Mr. C. A. Bolton) read several letters of apology, and announced donations from the following, towards the funds of the Society:—Mr. E. Harvey (Barron, Harvey and Co.), £5 5*s.*; Messrs. Hearon and Co. (per Mr. Rogerson), £5 5*s.*; Mr. R. Gibson, Manchester, £1 1*s.*; Mr. Ald. Witty, Hull, £1 1*s.*; Mr. J. S. Osborne, £1 1*s.*; Messrs. Burgoyne and Co., £1 1*s.*; Mr. Councillor Lees, £1 1*s.*; Mr. H. C. Mason, 5*s.*

After the usual loyal toasts had been duly honoured,

Professor Clowes proposed "Success to the Nottingham and Notts Chemists' Association." He said he was pleased to meet the members that night, and he had no doubt they had taken some interest in his endeavours at the University College to impart useful chemical instruction to those engaged in pharmacy in Nottingham. He hoped they would not think him too personal when he said that he was determined to make his department in the college very useful in that respect, and therefore, he had given a course of lectures which he thought were suited to the requirements of those attending the lectures. They represented such an important industry in the town that he considered that course of lectures necessary, and he thought he was justified in producing them. The numbers that had attended them and the course of instruction he had attempted had encouraged him to continue the lectures, which up to the present time had been eminently successful. They, as chemists, had to look upon themselves as the children of pharmacists. Early chemistry, no doubt, was concerned in the preparation of medicine, and the study of chemistry was pursued with the object of improving the preparation of existing ingredients, and the discovery of fresh ones. In the course of further remarks, Professor Clowes said he thought they did quite right in resenting the attempt which was made some time ago when the Institute of Chemists wanted to call themselves chemists *par excellence*, and oust them (his hearers) from the name of chemists. He (the speaker) considered that they had a perfect right to retain the name to which they had a special claim. Professor Attfield, who represented scientific chemistry perhaps more fully than anyone else, in a recent discourse had aimed at nothing less than making it a profession. Their President (Mr. Fitzhugh) considered that that aim was too lofty, but he (the speaker) disagreed with him on that point. Proceeding, Professor Clowes said chemists dealt in articles which ought to be pure, and it was extremely desirable that they should possess the confidence of the public. It was necessary that they should have some special education in order to perform their duties properly, and therefore he thought it was absolutely necessary that education should be given at the University College which would be of practical importance. He would be glad to receive any suggestions from the chemists regarding the instruction given in his own department. Being a public college it was necessary that it should do the work of the town. He thought the time had arrived when young men should be able gradually to receive such an education in Nottingham as would qualify them to pass at least their Minor examinations. That would be an attempt to introduce a system of gradual education in the place of the high pressure system. He would be glad to see a chemical association in Nottingham which would represent everyone engaged in chemistry. He was satisfied that the number of strictly scientific chemists was far too small, and, therefore, anyone engaged in chemical pursuits could not do better than take advantage of that admirable Association.

The Chairman, whose name was coupled with the toast, said he thought that meeting augured well for the future prosperity of the Society, the object of which, he took it, was to advance pharmaceutical chemistry. He quite agreed with the remarks of Professor Clowes, but, being a Conservative, he believed in advancing by degrees. The Chairman expressed the hope that they would get an amended Act of Parliament making Nottingham a centre, so that young men would not have to go to London to pass their Minor examinations. He thanked the company for the kind manner in which they had received the toast.

Mr. W. H. Parker also responded, and said the University College was an excellent institution, but it would not be much use without they had popular professors. He thought the young men of Nottingham owed Professor Clowes a debt of gratitude for the course of lectures he had given.

Mr. Holgate briefly proposed "The Pharmaceutical Society," to which Mr. Bolton felicitously responded, after which the annual collection was made on behalf of the Benevolent Fund, which amounted to £5 5*s.*

Mr. Beilby proposed "The President, Vice-President, and Officers of the Association," to which Mr. John Wilford and Mr. C. A. Bolton responded in appropriate terms.

The remaining toasts included "The Visitors," proposed by Mr. Warriner, and responded to by Mr. Harvey and Mr. Spencer; "The Chairman and Vice-Chairmen," proposed by Mr. Rogerson, and "The Ladies," proposed by Mr. R. H. Beverley, and responded to by Mr. Fred. Cobb.

Proceedings of Scientific Societies.

ROYAL INSTITUTION.

Professor Tyndall on Rainbows.

In a lecture delivered at the Royal Institution on Friday, the 18th inst., Professor Tyndall gave some interesting information concerning "Rainbows," and accompanied some of his statements by experiments. He commenced the subject by giving a detailed account of the history of the knowledge acquired concerning this phenomenon, stating that the most important discovery made in relation to it for a long period was the fact that the angle formed by the intersection of a line drawn from the observer to the rainbow with a line drawn from the sun to the rainbow always measured 41°. Taking this observation as a basis, Descartes explained theoretically the formation of the rainbow, and his theory was proved by Newton to be correct. The lecturer, after referring to the caustic curve, formed by aberration, then proceeded to show by means of diagrams the refraction and reflection which occur when a ray from the sun impinges upon a raindrop, and pointed out that these are the cause of the formation of the rainbow. He further showed that the phenomenon can only be seen when the observer and the sun are in the same relation as had been before noticed. In the continuation of his historical narrative, he designated Descartes and Newton as the discoverers of the formation of the "geometrical" rainbow, whilst he gave to Dr. Thomas Young the place of the first discoverer of the formation of the coloured zones or belts in the rainbow, adding that Sir George Biddle Airy had greatly contributed to prove the correctness of Dr. Young's statements.

Passing from the historical to the more general portion of the subject, Professor Tyndall explained the formation of the secondary rainbow, and the relations which its coloured zones bear to those of the primary rainbow. He then gave the particulars of a phenomenon noticed by himself, whilst residing in a hut on the Alps. Upon going to the door one foggy night, he saw his shadow thrown upon the fog by a small lamp hanging in the rear. This, in itself, was no new experience, but his attention was drawn to a well-defined white halo around the head of the shadow, a circumstance he had never observed before. He further mentioned that he had afterwards been able to reproduce this effect upon a small scale, and had arrived at the conclusion that this halo was really a rainbow, the formation of which was caused by the doorway allowing the light of the lamp to be thrown upon only a limited area of the fog. The fact that the halo was white Professor Tyndall considered to be due to the particles of moisture being in such a fine state of division that they were not able to form the prismatic colours; in support of this latter theory, he stated that he had passed a ray of electric light through an atmosphere of steam, with the result of obtaining a white halo. The formation of a white rainbow by the sun's rays, though rare, has been seen in foggy weather; indeed, one had been observed shortly before last Christmas. By means of the electric light, an artificially produced fine spray and jets of steam, this and other points were illustrated and it was shown that when the spray consisted of a liquid having a higher refractive index than water, such as spirit of turpentine or petroleum, a more circumscribed bow was formed than with water spray, whilst when both were used at the same time two bows were formed, one within the other, and each with its corresponding secondary bow. From the conditions of the experiments these results were not all witnessed by the company present, but Professor Tyndall met the difficulty as far as possible by entering the artificial mist, clad in a waterproof, and describing what he saw.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, January 17. Dr. W. H. Perkin, President, in the chair.

The following gentlemen were declared by the scrutators, Dr. Thorn and Mr. D. A Louis, duly elected Fellows of the Society:—B. H. Brough, G. Daubeney, C. C. Hutchinson, W. S. Kilpatrick, E. Matthey, H. Peile, J. W. Pallister, R. Romanis. S. G. Rawson, F. M. Rogers, W. Robinson, T. Stenhouse, W. O. Senier, J. A. Voelcker.

The following certificates were read for the first time:—L. Archbutt, W. H. Barr, D. Bain, P. S. Chantrell, H. C. Draper, A. F. Damon, V. Edwards, W. T. H. Elsley, T. Hilditch, R. E. Moyle, P. Morton, W. J. Orsman, F. R. Power, H. G. Shaw, E. F. Smith, A. E. Simpson, A. Tarn.

The President then called on Mr. C. T. Kingzett to read a paper—

On Camphoric Peroxide and Camphorate of Barium.—Brodie states (*Phil. Trans.*, 1863, 407) that when anhydrous camphoric acid is triturated with an equivalent quantity of hydrated barium peroxide in the presence of ice-cold water and the mixture filtered, there is obtained a solution which is slightly alkaline and which when rendered acid has the following properties: it bleaches indigo, oxidizes potassium ferrocyanide, decomposes hydriodic acid, and evolves oxygen when heated, but fails to give a blue coloration with chromic acid and does not discolour potassium permanganate. Brodie concluded from his analysis, etc., that a new substance was formed which was a barium salt of camphoric peroxide $C_{10}H_{14}BaO_5$, and not a camphorate of barium peroxide. The author believes that Brodie's experiments admit of another explanation, which is probably correct, viz., that when camphoric anhydride is triturated with water and barium peroxide, the anhydride is first resolved by the addition of a molecule of water into camphoric acid, which, in its turn, decomposes barium peroxide, forming camphorate of barium and peroxide of hydrogen. The author then gives a detailed account of his repetition, with some slight variations, of Brodie's experiments, and he concludes that barium peroxide only acts upon camphoric anhydride in the presence of water, and that the action is of a secondary character, the anhydride first becoming camphoric acid, which decomposes the peroxide of barium and yields camphorate of barium. He also incidentally proves the existence of a crystalline hydrate of camphorate of barium containing one molecule of water—

$$C_{10}H_{14}O_3 + H_2O = C_{10}H_{16}O_4$$
$$C_{10}H_{16}O_4 + BaO_2 = C_{10}H_{14}BaO_4 + H_2O_2.$$

Dr. Armstrong said that no doubt some organic peroxides, as acetic peroxide, did exist. In Mr. Kingzett's communication he had called attention to the results of one of his previous papers, in which he claimed to have shown that by the air-oxidation of turpentine camphoric peroxide was formed, which was the source of the peroxide of hydrogen: no doubt some peroxide was formed, but that this should be camphoric peroxide appeared to him very doubtful, as there seemed to be no relation between the terpenes and camphor.

Mr. Kingzett, in reply, said it was principally from Brodie's experiments that he had concluded that camphoric peroxide was formed in the oxidation of turpentine; although peroxides of monobasic acids were known, if camphoric peroxide did not exist he did not think any peroxides of bibasic acids had yet been discovered.

The Secretary then read the following communications:—

Supplementary Note on Liebig's Production of Fulminating Silver without the use of Nitric Acid. By E. Divers and Michitada Kawakita.—The authors have succeeded in obtaining a very small quantity of fulminate by the action of nitrous acid, but under conditions which deprive its production of all significance. The fulminate was only produced when the temperature rose to about 60° and the liquid contained nitric acid.

On the Decomposition of Silver Fulminate. By E. Divers and Michitada Kawakita.—Silver fulminate, when treated with hydrochloric acid, yields as is the case with mercury fulminate, formic acid and hydroxyammonium chloride, but the authors have, as yet, only found two-thirds of the calculated quantity of each of these bodies. Traces of ammonia and hydrocyanic acid are also produced.

On Hyponitrites. By C. Divers and Tamemasa Haga.—In this paper the authors resume an investigation commenced by Divers in 1871; they criticize especially the results and conclusions of Berthelot and Ogier, who gave to silver hyponitrite the formula $Ag_4N_4O_5$. These chemist. do not seem to have thought that an acid of such a strange constitution as $H_4N_4O_5$ might be a mixture of hyponitrite, having Divers' constitution (HNO) mixed with nitrite and nitrate. The authors of the present paper have made many experiments purifying the hyponitrite in various ways. The final experiment consisted in dissolving the hyponitrite in nitric acid, precipitating with sodium carbonate, washing with water, acetic acid and again with water; all the operations being performed in an atmosphere of carbonic acid. This resolution and reprecipitation were performed several times; the product was finally dried in an atmosphere of carbonic acid, over sulphuric acid. The salt gave 77·69 per cent. of silver. AgNO contains 78·3 per cent. The constitution of the salt is, therefore, AgNO. The authors have hitherto failed to prepare hyponitrites either by Menke's method, heating potassium nitrate with iron filings, or by Zorn's process of using ferrous hydrate as the reducing agent.

Dr. Japp pointed out that Zorn had prepared an acid barium hyponitrite, and had shown that nitrous oxide was evolved when a hyponitrite was heated.

The Society then adjourned to February 7, when a paper "On the Influence of the Temperature of Distillation on the Composition of Coal Gas" will be read by L. T. Wright.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, January 10, Mr. H. G. Greenish, Vice-President, in the chair.

Mr. W. H. Ince read a paper on "Hydroxylamine," of which the following is the substance:—

Hydroxylamine.

BY W. H. INCE.

This compound, NH_3O, was discovered by Lossen in 1865, when he obtained it by acting on nitrous acid with tin and hydrochloric acid.

It may be prepared by several methods which involve the action of nascent hydrogen upon an oxide of nitrogen, most readily by acting on zinc by dilute sulphuric acid, to which a few drops of nitric acid have been added.

Another easy method of preparation, lately discovered by Dr. Divers, is by acting on tin by a mixture of strong hydrochloric acid with one tenth of nitric acid.

$$9\,HCl + 4\,Sn = 4\,SnCl_2 + 4\,H_2 + HCl$$
$$4\,H_2 + 8\,HNO_3 + HCl = (NH_3O.\ HCl) + 3\,H_2O$$

The tin is precipitated by sulphuretted hydrogen, and the liquid evaporated over a water-bath to dryness; the resulting saline mass, which is a mixture of hydroxylamine hydrochloride and ammonium chloride is boiled with absolute alcohol, which dissolves out the hydroxylamine salt and a little of the ammonium chloride. The ammonium salt is precipitated by platinum perchloride, and the resulting hydroxylamine hydrochloride may be crystallized out, either from alcohol or water.

The formation of the ammonium salt is mainly due to the action of hydroxylamine on the metal.

I found that instead of precipitating the tin as sulphide, if sodium carbonate were added to the solution, so as to just render it alkaline (and so precipitate the tin as carbonate), then by filtering and carefully heating the filtrate over a water-bath until it ceases to smell of ammonia, the ammonium salt is decomposed, ammonia being given off, leaving hydroxylamine unacted upon.

But if this solution is evaporated or allowed to stand, the hydroxylamine is decomposed.

The hydroxylamine can be obtained from the liquid by reacidulating with hydrochloric acid, evaporating and extracting with absolute alcohol: on evaporating the alcoholic solution the hydroxylamine hydrochloride is deposited in crystals.

Another method consists in dissolving dry mercury fulminate in hydrochloric acid.

$$\underset{\text{Mercury fulminate.}}{HgC_2N_2O_2} + 4\,H_2O + 4\,HCl = \underset{\text{Hydroxylamine HCl.}}{2\,NH_3O.HCl} +$$
$$HgCl_2 + \underset{\text{Formic acid.}}{2\,H_2CO_2.}$$

If the mercury fulminate is damp, hydrocyanic acid and hydroxylamine are formed.

I have found that many substances containing the NO_2 group when acted upon by nascent hydrogen, or by being dissolved in hydrochloric acid, reduce mercury and copper salts, pointing to the presence of hydroxylamine.

Thus pyroxylin (gun cotton), $C_6H_7(NO_2)_3O_5$, xyloidin, $C_6H_8NO_2O_3$, and nitromannite, $C_6H_8(NO_2)_6O_6$, treated as above, give hydroxylamine reactions.

I found that the action of benzene upon nitric acid yielded no hydroxylamine, but nitrobenzene, $C_6H_5NO_2$, when treated with zinc and hydrochloric acid, and the aqueous solution filtered from the aniline answered the tests for hydroxylamine.

Aniline was not found to reduce mercury or copper salts as hydroxylamine does.

I have endeavoured to obtain hydroxylamine by oxydizing ammonia, first by passing a stream of oxygen into a warm solution of ammonia (specific gravity ·88), and, secondly, by leaving ammonium chloride in an oxidizing mixture, such as sulphuric acid, oxide of manganese, and potassium bichromate; but in neither case was I successful.

Picric acid, which from its constitution $C_6H_2(NO_2)_3OH$ might be expected to yield hydroxylamine, gave no traces when dissolved in hydrochloric acid, or when acted on by nascent hydrogen.

The formation of hydroxylamine has usually been ascribed to the action of nascent hydrogen liberated by the action of the acid on the metal, for it can be obtained by passing nitrogen tetroxide into a flask in which hydrogen is generated—

$$2\,NO_2 + 6\,H_2 = NH_3O + NH_3 + 3\,H_2O.$$

But Dr. Divers asserts that no nascent hydrogen is required for the formation of hydroxylamine when nitric acid acts upon a metal.

The following is the probable reaction with zinc and nitric acid—

$$7\,HNO_3 + 3\,Zn = NH_3O + 2\,H_2O + 3\,Zn\ (NO_3)_2,$$

In all cases hydroxylamine combines with the acid present forming a salt, as when hydrogen is liberated from zinc and sulphuric acid, the hydroxylamine is produced as sulphate $(NH_3O)_2H_2SO_4$. Hydroxylamine may be isolated by treating the sulphate with baryta water, which precipitates barium sulphate leaving hydroxylamine in solution—

$$(NH_3O)_2H_2SO_4 + BaH_2O_2 = 2\,NH_3O + BaSO_4 + 2H_2O.$$

It is an unstable colourless fluid, and uncrystallizable. It is quickly decomposed by strong potassium hydrate solution, giving off nitrogen and ammonia.

The constitution of hydroxylamine, according to the formula NH_3O might be expressed in two ways, nitrogen either acting as a triad or pentad element—

$$N\begin{cases}H\\H\\O.H\end{cases}\qquad O{=}N\begin{cases}H\\H\\H\end{cases}$$

As the salts of hydroxylamine are formed by taking the whole acid group into the element, the former is preferable, in fact hydroxylamine may be regarded as ammonia with the hydrogen replaced by the hydroxyl group OH. This is further confirmed by the fact that hydroxylamine is readily converted into ammonia.

All the simple salts of hydroxylamine are additive compounds, the principal ones are hydrochloride, $NH_3O.HCl$; sulphate, $NH_3O_2H_2SO_4$; nitrate, $NH_3O.HNO_3$, and cyanide, $NH_3O.HCN$. (isomeric with urea).

All the salts are soluble in water and absolute alcohol, and all decompose when strongly heated with violent evolution of ammonia and oxygen.

Hydroxylamine also forms substitution products, where one or more hydrogen atoms are replaced by monad organic radicles; these form simple salts with the acids.

$$\underset{\text{Hydroxylamine.}}{N\begin{cases}H\\H\\OH\end{cases}}\qquad \underset{\text{Ethyl hydroxylamine.}}{N\begin{cases}C_2H_5\\H\\OH\end{cases}}\qquad \underset{\text{Diethyl hydroxylamine.}}{N\begin{cases}C_2H_5\\C_2H_5\\OH\end{cases}}\qquad \underset{\text{Tribenzy hydroxylamine.}}{N\begin{cases}C_7H_5O\\C_7H_5O\\O.C_7H_5O\end{cases}}$$

Hydroxylamine acts in two ways, either as a powerful reducing agent or as an oxidizer.

As a reducing agent it splits up into N, H_2O, and H, the H reducing metallic salts.

In solutions made alkaline with potassium hydrate it reduces cupric sulphate, throwing down a yellow precipitate, which is further reduced to red oxide on boiling.

$$2\,NH_3O + 2\,CuO = Cu_2O + 3\,H_2O + N_2.$$

It reduces silver and mercury salts to their respective metals.

1. $NH_3O + AgNO_3 = Ag + HNO_3 + H_2O + N.$
2. $NH_3O + HgCl_2 = HCl + HgCl. + H_2O + N,$
then $NH_3O + HgCl = HCl + Hg + H_2O + N.$

It also reduces tin, lead, nickel and zinc salts.

When it acts as an oxidizing agent it gives up its oxygen, liberating ammonia.

Thus it converts aldehyde, CH_3COH, into acetic acid—

$$NH_3[O.CH_3COH].$$

It acts in a peculiar manner on dibromononitroethane, forming ethylnitrolic acid—

$$CH_3.C.Br_2.NO_2 + NH_3O = CH_3C.NOH.NO_2 + 2\,HBr,$$

and on thio-carbanilide, precipitating sulphur.

Hydroxylamine forms substitution products with benzyl, anisyl and cinnamyl, by replacing the hydrogen atoms of the hydroxylamine by the radicals.

First, those in which a chloride, as when benzoic chloride forms a substitution product with hydroxylamine hydrochloride, producing dibenzhydroxamic acid—

$$2\,NH_3O.HCl + 4\,C_7H_5O.Cl + 2\,Na_2CO_3 =$$
$$N.C_7H_5O.C_7H_5O.OH + 6\,NaCl + 3\,CO_2 + 3\,H_2O.$$

This acid forms a potassium salt, which, when acted on by ethyl or methyl iodide, produces ethyl or methyl-dibenzhydroxamate—

$$C.C_7H_5O.C_7H_5O.OK+C_2H_5I = N.C_7H_5O.C_7H_5O.O.C_2H_5+KI.$$

The ethyl salt is reconverted into hydroxylamine by the action of hydrochloric acid.

A second class of substitution products are not directly formed from hydroxylamine, but by the action of nascent hydrogen on a nitrate, such as ethylnitrate—

$$C_2H_5O.NO_2+3H_2=N.H_2.OC_2H_5+2H_2O.$$

A third class are obtained by the action of a chloride on a silver salt of a hydroxamic acid. This compound may be considered as hydroxylamine in which the three hydrogen atoms have been replaced by organic radicals.

Dibenzanishydroxylamine is formed by the action of anisyl chloride on silver dibenzhydroxamate.

$$N.C_7H_5O.C_7H_5O.OAg+C_8H_7O_2.Cl = N.C_7H_5O.C_7H_5O.O.C_8H_7O_2+AgCl.$$

There are three isomeric bodies having the same formula as dibenzanishydroxylamine, but slightly differing in their reactions with potassium hydrate and hydrochloric acid.

This may be explained by supposing that the different radicals $C_8H_7O_2$ and C_7H_5O take different places in the molecule.

In considering the action of metals upon nitric acid two classes of reactions occur, depending on the metal which is employed.

First, those reactions where nitrates and no hydroxylamine are formed, and secondly, those in which hydroxylamine or ammonia results. Silver and mercury are metals which give rise to the first class of reactions. Silver with nitric acid forms silver nitrite and nitrate, but no hydroxylamine.

$$2Ag+HONO_2=HO.Ag.+AgNO_2$$

$$\left\{\begin{array}{l} HO.Ag.+HONO_2=AgO.NO_2+H_2O \\ AgNO_2+HONO_2=AgO.NO_2+HNO_2 \end{array}\right.$$

The second or zinc-tin class differs from the silver class by forming no nitrite directly from nitric acid, but producing hydroxylamine and ammonia.

When this reaction is utilized for the preparation of hydroxylamine, it is usual to add a second acid, as hydrochloric or sulphuric, but the hydroxylamine is directly eliminated from the nitric acid:—thus

$$7HNO_3+3Zn=NH_3O+2H_2O+3Zn(NO_3)_2$$

and not indirectly obtained by nascent hydrogen from the action of the second acid on the metal.

The use of the second acid is to set free the nitric acid as soon as it becomes metallic nitrate, and so keep the nitric acid to the end of the operation free to be acted upon. Without the second acid only one-seventh of the nitric acid is converted into hydroxylamine.

When iron is dissolved by nitric acid a large quantity of ammonia is formed, but no hydroxylamine can be detected; this production of ammonia is probably due to a secondary reaction in which hydroxylamine is reduced by the ferrous salt as soon as it is formed.

The paper was fully illustrated by experiments, and a discussion followed in which the Chairman, Secretary, Mr. R. W. Giles, Mr. Joseph Ince, Messrs. Dymond, Elliott and Lowe joined.

A vote of thanks was passed to Mr. Ince.

The Reporter on Inorganic Chemistry, Mr. A. J. G. Lowe, then made two reports on inorganic chemistry. In the first report he drew attention to the white phosphorus of Messrs. Remsen and Keiser (*Chem. News*, xlviii., p. 201), and exhibited a specimen, together with the apparatus by means of which it had been prepared just before the meeting. The apparatus was a flask and receiver containing ice and water, similar to that described by Remsen and Keiser, in which stick phosphorus could be distilled and condensed quickly. A current of carbon dioxide was, however, employed, as on the whole preferable to the hydrogen used by the original experimenters, and the condensed phosphorus, which collected in a thick layer on the surface of the ice and water in the receiver, was a white or yellowish white spongy mass, in appearance between that of flowers of sulphur and phosphoric anhydride. Under the microscope it was seen to consist of minute adhering globules which did not affect polarized light. This distilled phosphorus is light and plastic, and placed in water slightly warm at once melts and assumes the ordinary wax-like condition. It becomes warm and assumes this same condition when dried and exposed to the air. It is not an allotropic modification, but ordinary phosphorus, sublimed and condensed in minute particles. It is thus perfectly analogous to sublimed sulphur. Mr. Lowe therefore suggested that it should be called "sublimed phosphorus" rather than "white phosphorus," which might be thought to imply an allotropic modification.

The second report was upon the "Fluorescence of Iodine Vapour," which had been recently investigated by Lommel (*Wiedemann's Ann.*, 1883, No. 6, p. 356; *Phil. Mag.*, vol. 16, No. 102, p. 463). This was shown experimentally, and it was pointed out that it was the first recorded instance of a fluorescent vapour, and further, that unlike all other cases of fluorescence the refrangibility of the violet and ultra-violet rays was unaffected.

These reports were discussed by the Chairman, Secretary, Mr. R. W. Giles, Mr. Joseph Ince, and also by Messrs. Baily, Elliott and Short.

The Secretary then announced that the Executive Committee had made a grant from the Research Fund to Mr. W. H. Ince in order to defray the expenses connected with his work upon hydroxylamine.

Parliamentary and Law Proceedings.

The Sale of Poisons.

At Newton Abbot Petty Sessions, on Tuesday, J. H. Bibbings, a local chemist, pleaded guilty to a charge of selling prussic acid to a lady without obtaining her signature. The customer, Mrs. Jane Pinsent, obtained the drug about a fortnight ago, on the plea that she was going to kill a dog, but on the following day she poisoned herself. The defendant, who expressed regret for what had occurred, was fined £2.—*Daily Telegraph.*

Fatal Use of Quack Medicine.

An inquest was opened at Moss Bank, near St. Helens, on Wednesday, the 16th, by Mr. W. Hardy, on the body of Samuel Yates, aged nine years, son of John Yates, collier. The lad, it appeared, had enjoyed good health up to the previous Saturday, when he complained of feeling sick. Mrs. Yates gave him some warm tea, but he continued to vomit until noon, when she went to the shop of William Ashall, grocer, and purchased threepennyworth of "Indian tincture," the whole of which she gave to the boy in warm water and then put him to bed. About six o'clock deceased was breathing heavily, and as she was unable to awaken him she carried him downstairs and laid him across her knee, but he died shortly afterwards. Dr. Anderson, of Billinge, and his assistant, Mr. Nicholson, of Rainford, made a *post-mortem* examination of the body on Tuesday. They stated that the body was that of a healthy lad. All the organs were normal. Having heard the mother's evidence, and judging from the symptoms generally, they were of opinion that death had been caused by some narcotic poison, but what they were not in a position to say. The stomach and a portion of the duodenum had been placed in separate jars, and sent to Dr. Campbell Brown for analysis.

Mrs. Yates said the grocer did not label the glass and did not tell her what was the dose for a child.

Mr. Ashall produced the bottle from which he had supplied Mrs. Yates, on the label of which it was stated: "The only original highly medicated tincture for coughs, colds, bowel complaints, etc. Doses: For adults; one tablespoonful; ten to fifteen years, half a tablespoonful; seven to ten years, one large teaspoonful; two to seven years, half a teaspoonful, to be taken in warm water or gruel. Now ready to be used everywhere. Admirably adapted for everybody. Calculated to save scores of pounds in doctors' bills. A real boon to the people of this country. Sold here at 3*d.* per ounce." There was no maker's name on the bottle, and Mr. Ashall said it came from Daubhill, near Bolton, but he did not know the name of the man who brought it. He had not told Mrs. Yates what she ought to give the child, thinking she knew, as it was a common medicine. It seemed that six or seven times the proper quantity had been given to the child through the ignorance of the mother.

The inquest was then adjourned until Saturday, and at the adjourned inquest, in answer to the coroner, the police officer said he had made inquiries, and found that the stuff had been supplied by a Mr. Riley, wholesale druggist, Daubhill, near Bolton.

The coroner then told the jury the inquest would have to be adjourned so that the analyst, Dr. Campbell Brown, of Liverpool, might get some indication of the nature of the ingredients of the bottle.

Alleged Poisoning of a Chemist and Druggist.

On Monday, Mr. G. H. Hull, Coroner for the Western Division of Surrey, resumed an adjourned inquiry at Wandsworth Prison, respecting the death of George Robinson, chemist, of Walworth, aged 51, committed for three months' hard labour by the magistrate at Lambeth Police Court for an assault on his wife. The deceased was admited to the gaol on December 19, in pursuance of his sentence, which followed a week's imprisonment in the House of Detention, at Clerkenwell. It was stated that while at the police court he partook of a meat pie and liquid refreshment, which were brought to him, it not being contrary to regulations for friends to supply prisoners with diet while under remand. The man died from arsenical poisoning an hour or two after his admission to Wandsworth Prison, and the evidence of Captain Colville, the Governor of the gaol, was to the effect that when received at half-past five in the evening, the prisoner was very ill indeed, and apparently in great pain. The man could not account for his symptoms, and was treated in the infirmary, where he died.

Dr. Mosse, who was acting for the medical officer of the prison, deposed that he saw the deceased about eight o'clock on the night of December 19. He was then in a state of collapse, and complained of pains in the abdominal region. He was constantly sick, and had frequent diarrhœa; his heart was beating quickly but feebly, and his pulse was barely perceptible. Witness was not present at the time of death. Deceased complained of extreme thirst, and his tongue was dry and parched. He told witness that he was quite well in the morning, and that his symptoms came on at three o'clock in the afternoon. He also said that he was very ill in the van on the way to the prison. Witness ordered him to the infirmary, and he was taken from the cell. A *post-mortem* examination was made four days after death, Dr. Winter, the medical officer to the prison, being present. The body was well nourished. The result of the *post-mortem* was negative—the organs being all healthy excepting the lungs, and there being no apparent cause of death. The stomach contained about three ounces of dark, bilious-looking fluid, which was preserved in a jar and afterwards handed to Professor Stevenson, of Guy's Hospital, for analysis.

Professor Stevenson, deposed that he received a jar containing the stomach of the deceased and the liquid contents. There were no recognizable particles of food in either the stomach or the liquid, and no unusual appearances or signs of disease, except a slight redness of the inner coat of the stomach. From the fluid in the jar he obtained a quantity of arsenic—about a quarter of a grain. It was nearly all in a soluble form, and he could not detect any solid visible particles of arsenic or its compounds. There were also traces of bismuth in the stomach—no doubt given as a medicine, as deposed to by Dr. Mosse. The vomit of the deceased, which consisted of 104 grains of dried matter, contained a white powder, which on analysis, proved to be the subnitrate of bismuth. The vomit also contained arsenic equal to more than one-third of a grain.

By the Coroner.—The arsenic found was only the residue, but no doubt a quantity of the mineral poison was absorbed into the blood or ejected from the system in the vomit and by other means. If a fatal dose had been given, he found as much as he should have expected to find in the body after death. He actually found about half a fatal dose, and it was more than equal to six or even eight medicinal doses. It was not likely that the bismuth contained arsenic as an impurity, and the substance must have been taken or given for the purpose of causing death. He had found no clue as to the form in which the arsenic had been administered. He mentioned this because the sale of such a deadly poison was generally associated with some other compound for the purpose of identification.

The inquiry was then adjourned.—*Times.*

Lime Water.

Sir,—The fellowing may be interesting as bearing on the subject of Mr. C. Abraham's letter in your last issue:—In the year 1879, I was engaged to investigate the cause of an unsightly and extensive efflorescence on the bricks of a new public building in the neighbourhood; the incrustation proved to be almost pure sulphate of soda; indeed, a sample of well crystallized "Glauber's salts" prepared from it was sent in with the report, but, for some time, I was unable to point out the source of the soda. The bricks, the clay and the gravel were examined without success, but in the lime both potash and soda were found in the caustic condition; the proportion given in my notes being 0·32 grains caustic soda and 0·3 grains caustic potash in 4 ounces of lime. This is hardly sufficient to account for any appreciable increase in the alkalinity of lime water prepared by the official process, but it is interesting as confirming Mr. Abraham's view as to the presence of caustic alkalies in lime. The proportions, no doubt, differ in different samples.

The Wyle Cop, Shrewsbury. Thos. J. Blunt.

S.Y.—The arrangement of giving an unqualified person an interest in a branch shop would be illegal under the existing law, and should the Pharmacy Bill pass in its present form it will be unlawful to carry on a branch establishment except under the charge of a qualified person.

A.P.S.—We do not agree with you that the "means for attaining so many useful hints is entirely taken away," since the memoranda are all indexed and available for reference. The dose of hydrogen peroxide (10 vols.) that has been recommended is one-half to two drachms.

Associate.—We are not aware that such a photograph has been taken.

Anon.—An indiarubber cement, suitable for fastening the tyres on bicycle wheels, may be made by digesting during three or four weeks with frequent agitation 1 part of shellac in 10 parts of liq. ammon. fort. in a wide-mouthed bottle, placed in a warm spot. The mixture first forms a transparent mass and then becomes liquid.

J. E. L.—You are recommended, to test the iodine used.

W. Wilkinson.—We understand that the subject is already being inquired into and therefore defer the publication of your letter for the present.

A. B.—We do not remember the experiments. Are you thinking of Professor Tyndall's paper on the "Conversion of Radiant Heat into Sound"? (See *P. J.*, [3], xii., 628).

Communications, Letters, etc., have been received from Messrs. Burchell, Cock, Dispenser, J. E. L., N. B., A. P. S., T. G. R.

"THE MONTH."

At the drug sales this month an unusually large quantity of assafœtida was offered and some very fine "Socotrine" aloes. The Socotrine aloes above alluded to came in small tin dishes and in small white saucers, in which the juice had apparently been poured to solidify it. On account of the bad quality of this drug in recent years the cultivation of the aloe yielding it is deserving of the attention of planters in the colonies, especially since the plant (*Aloe Perryi*) has been brought to Kew Gardens by Professor J. B. Balfour and there can be no great difficulty in obtaining it for cultivation. There was also exposed for sale a large white-looking variety of jalap from Mexico, which bore some resemblance to what has been described as stalk jalap (*Ipomœa Orizabensis*). A root was also offered (apparently from the west of Africa) under the name of pareira brava root, which resembled the genuine article in the black colour of the exterior surface, but was evidently not the root of *Chondrodendron tomentosum*, the concentric rings being narrower and of much more dense structure. This false pareira brava was offered without reserve and there were 164 "pockets" of it for sale. It was bought at a low price by one or two firms, and may, therefore, be expected to be met with in retail commerce. It was interesting also to note among the drugs offered for sale "Syrian" cummin seed, showing that cummin is still an article of commerce in that country as it was in the times of the Evangelists. There were also a number of Brazilian drugs, including one not observed before, "tinguasseba" bark (*Xanthoxylum Tinguaciba*, St. Hil.), which is used in Brazil for intermittent fevers. Some bark of the balsam of peru tree from which the balsam had been prepared was put up for sale, but for what purpose it was imported did not appear.

The unusually fine and mild weather of the last few weeks has in many places caused a most precocious development of vegetation. The coltsfoot was seen in blossom on December 30, wild primroses were sold in the streets early in the month, and the roses are already putting forth green leaves in the gardens. In a list of plants given in *Nature* (January 10, p. 236), to call attention to the mildness of the season, there are mentioned among others *Centaurea Scabiosa*, *Achillea Millefolium*, *Pimpinella Saxifraga*, *Pastinaca sativa* and *Rumex crispus*. These were gathered on December 24 and 26, in the neighbourhood of Bath and Bradford-on-Avon. A correspondent at Reigate forwarded on January 14 a box full of blossoms of *Chrysanthemum segetum*, gathered in a turnip field. Another correspondent writes this week that in the neighbourhood of Poole the catkins of the willows are open and camellias are in full bloom out of doors, and on all sides there are reports of plants in blossom which are rarely seen in that condition in January. It is quite possible, however, that this may not be the case in sandy or dry soils, since the Kew Gardens do not present signs of unusually early vegetation. The Christmas rose, *Helleborus niger*, is in full bloom and the bearsfoot (*Helleborus fœtidus*) is already in bud; but the mezereon does not appear as yet to have opened its flower buds, and neither the Jeffersonia nor Sanguinaria, both early flowers, have made any start. In the Economic House the nutmeg is coming into flower, and the *Olea fragrans* perfumes the whole compartment with its delicate odour.

At the meeting of the Linnean Society held on January 17, Mr. J. G. Baker read a paper on the tuberous species of *Solanum*. There have been about nine hundred species described as belonging to the genus, which, however, Bentham and Hooker could reduce to about seven hundred. Only a very small proportion of these have tuberous underground stems; this section including, according to M. Dunal's monograph in De Candolle's 'Prodromus,' twenty species, all natives of the South American continent, and as far north as Mexico and Texas. These twenty species Mr. Baker thinks should be reduced to six, with well-marked specific characters. While from a botanical point of view the range of *Solanum tuberosum* has thus been unduly narrowed by separating from it forms which are not specifically distinct; from a popular point of view it has, on the other hand, been erroneously extended, from the fact that the late Mr. Darwin, in his 'Voyage of the *Beagle*.' described the potato as growing as far south as 50° S. lat. But Mr. Baker has clearly determined that the species gathered there by Mr. Darwin is not *Solanum tuberosum*, but a quite distinct species, *S. Maglia*. The geographical range of the true *S. tuberosum* extends from Chili to Mexico, though it is doubtful to what extent it is native in the equatorial regions, having been cultivated from time immemorial by the Indians. Besides *S. Maglia*, the most important of the tuberous species are *S. Commersoni*, widely dispersed through Uruguay and Paraguay, and *S. Jamesii*, a native of New Mexico. The tubers of the latter species are, however, very small, not much larger than a hazel-nut. The remaining species are but little known, and probably are of no economic value. The only one ever cultivated in Europe is *S. Maglia*, which was at one time grown at Chiswick by Mr. Sabine, but has long gone out of cultivation. By a visit to the establishment of Messrs. Sutton at Reading, Mr. Baker satisfied himself that all the potatoes grown in this country are varieties of *S. tuberosum*. As regards any practical hints to potato growers, Mr. Baker pointed out that the whole energy of cultivators has been thrown into the production of the tuber at the expense of the flower and seed, a proceeding which cannot fail ultimately to decrease the vigour of the plant, and render it an easy prey to the attacks of enemies, animal or vegetable. The early spring varieties now never flower. An experiment of Andrew Knight's demonstrated that if the tubers are removed, or the supply of food to them restricted, the plant at once commences to flower. It would be quite worth while for potato growers to turn their attention to the cultivation of others of the American tuberous species, especially *S. Maglia* and *Commersoni*. The former in particular, coming from Southern Chili, would appear to be especially adapted for cultivation in Scotland and Ireland, its native country being much more rainy than that of *S. tuberosum*. Hybridizing might also be tried with advantage. The annual value of the potato crop in the British Isles Mr. Baker estimates at not less than £20,000,000.

On December 17, Professor Dickson read a paper before the Royal Society of Edinburgh, "On the Structure of the Seedling Pitcher of Nepenthes." He has found that there is a row of button or cushion-shaped glands just within the inflexed edge of the rim of the pitcher, and in the adult plant he has discovered just above the free edge of the inflexed rim a single line of orifices alternating with the ridges of the rim. Each of these proved, on dissection, to be the opening of a canal-like furrow, from the base of which a cellular nipple-shaped gland, or rather the apex of one, projects, the bulk of the gland being immersed in the substance of the rim. The glands vary in length, according to the species, from $\frac{1}{37}$ (*N. ampullaria*) to $\frac{1}{12}$ of an inch (*N. distillatoria*, *N. phyllamphora*). These glands are believed by Professor Dickson to secrete honey.

In the *Journal of Botany* for this month, Mr. H. Groves gives an illustration and description of the new British *Chara*, *C. Braunii*, Gm., which was discovered by Mr. C. Bailey, near Reddish, Lancashire. In the same journal Mr. F. Townsend has some interesting remarks on *Erythræa capitata*, Willd, var. *sphærocephala*, Towns., showing that the flowers are evidently proterogynous, and that in consequence of the exterior surface of the petals of the unopened flowers being of a brighter colour than the interior at the time when the stigma is protruded, the colour of them attracts insects, so that cross-fertilization is ensured. After fertilization the corolla grows longer so as to enclose the stigma, and the anthers are protected until they have matured.

Mr. C. Woolley Dod, in the *Gardeners' Chronicle* (Jan. 19, p. 90), has pointed out a curious habit in one of our rare British plants, *Lithospermum purpuro-cæruleum.* He has observed it on limestone rocks in the Vale of Clwyd, Denbighshire, where he noticed that the terminal tufts of leaves at the apex of the shoots put forth roots which, when the arched stem touched the ground late in the year, entered the ground and formed new plants, the connecting stem decaying and ultimately disappearing. The same habit has been observed in another rare British plant, *Scirpus Holoschœnus*, in which the roots are given off at the base of the inflorescence. It may also be commonly observed in brambles, but does not appear to have been previously recorded concerning the *Lithospermum*, which, at least in Devonshire, ripens its fruit freely. It would be interesting to know if this be the case also in Denbighshire.

Mr. W. Watson, in the same journal, gives an account of the germination of the *Nymphæa*, with an illustration exhibiting the curious pseudo-endogenous character of the embryo and germination, which taken in conjunction with the endogenous structure of the rhizome and the hydrocharoid habit of the plant has led to the genus being referred by some authors to the *Endogenæ.* Mr. Watson shows that although one group of species open at night and another during the day this is not affected by reversing the conditions, those which open during the night doing so even in brilliant gas light, but refusing to open during the day when kept in total darkness. He finds also that the pollen will sink in water, and is therefore not likely to be floated away from the flowers.

A very pretty little marsileacean plant from Carolina, *Azolla Caroliniana*, has recently become naturalized in a large pond near Pinner, Middlesex, in which it overrides the duckweed; it is also spreading on other ponds of the neighbourhood, apparently having originated from private gardens close by ('Science Gossip,' Dec., p. 279).

M. C. Naudin furnishes an interesting account (*Annales Sc. Nat.*, [6], vol. xvi., p. 337) of the species of *Eucalyptus* introduced into the Mediterranean region, and more particularly of those which have arrived at the adult stage in France and Algeria, thirty years having now elapsed since the culture of the species of this genus was commenced in France. He states that so far as regards production in timber alone the *E. globulus* has four times the value of the oak tree, since the growth of twenty-five years equals that of an oak of one hundred. By cutting down the trees in the winter, when the wood has the least sap in it, the tendency of the wood to split is avoided. He makes the suggestion that in the future a residence in the *Eucalyptus* groves of Algeria may become a part of the treatment prescribed to sufferers from phthisis. The astringent bark of the tree, which is shed naturally and thus has an advantage over such as are obtained only by the destruction of the tree, might, he believes, be used in the manufacture of leather. Owing to the rapid growth of the tree it is also likely to prove of great value as firewood, which, in France, is an important consideration. *E. melliodora* he considers not only valuable as a decorative tree, but also for the bee-keeper, on account of the abundance of fragrant flowers which it bears.

Chlorophyll has been the subject of a considerable number of investigations, but the problem of its nature and constitution remains at present far from being solved. Dr. Schunck, attacking the question from the chemical side, has in a communication to the Royal Society made known his reasons (*Chem. News*, xlv., 5) for supposing that it is a glucoside, resembling in this respect certain other colouring matters that occur ready formed and in a free state in vegetable organisms, such as those of turmeric and safflower. The greatest obstacle in deciding this point has been the difficulty experienced in obtaining pure chlorophyll, Dr. Schunck considering the so-called "crystallized chlorophyll" to be really a decomposition product. The process followed was to extract spinach leaves with boiling alcohol, filter off the deposit that formed after a time and mix with the tincture an equal volume of ether and about two volumes of water. Upon standing the liquid separated into two layers, the upper one green and containing all the chlorophyll, the lower bright yellow and containing colouring matter and a substance reducing Fehling's solution. The upper layer was separated, a little fresh ether added, and again washed with water, the process being repeated until the fresh lower layer ceased to give the glucose reaction. The upper layer then left upon evaporation a bright green residue, which although not pure chlorophyll was free from all matter soluble in water. This residue treated in the cold with concentrated sulphuric acid formed a green solution, which after standing some time gave on the addition of water a dark green precipitate, consisting essentially of the phyllocyanin and phylloxanthin of Fremy, whilst the filtered liquid gave the glucose reaction. Dr. Schunck therefore infers that the green leaves of all plants contain a glucoside, insoluble in water, but soluble in alcohol and ether, and that this is probably chlorophyll.

The separation of digitalin and the bodies which accompany it in *Digitalis purpurea* has been the subject of many communications. The method usually followed in Germany depends upon digitalin being precipitable by tannic acid, whilst the French method is based upon digitalin and digitin being thrown down by water from an alcoholic extract of the plant, the digitalein, being easily soluble in water, remaining in solution. Herr Palm recommends (*Zeits. anal. Chemie*, xxiii., 22) a process for the separation and quantitative determination of digitalin, digitalein and digitin, which consists in treating an aqueous extract of the plant that has been completely decolorized by repeated filtration through animal charcoal with a solution of lead acetate and alcoholic ammonia, then making the precipitate, which consists of the glucosides in combination with lead oxide, into a thin paste with water, and decomposing it by means of sulphuretted hydrogen. Upon filtration the digitalein passes into the aqueous filtrate; whilst the digitalin can be removed from the residue on the filter by treatment with chloroform and the digitin by means of alcohol. Picrotoxin and solanin are also thrown down under similar conditions; but whilst the digitalin precipitate is gelatinous and becomes flesh-coloured upon the addition of concentrated sulphuric acid, a picrotoxin precipitate is more slimy and coloured saffron yellow by sulphuric acid, and a solanin precipitate is sandy, and with sugar and sulphuric acid becomes first violet and then blne.

"Cascara amarga," also known in commerce as "Honduras bark," obtained from a tree indigenous to Mexico, has been submitted to examination by Mr. Thompson in the laboratory of Messrs. Parke, Davis and Co. He reports (*Ther. Gazette*, v., 8) that he has isolated from it a crystalline alkaloidal substance, which is freely soluble in chloroform, less soluble in ether and benzine and insoluble in dilute acids and fixed alkalies. Only amorphous salts of this substance were obtained, which were freely soluble in water, but insoluble in chloroform or ether. As the plant yielding the bark is supposed to belong to the genus *Picramnia*, it is proposed that the alkaloid, of which the yield is about 3 per cent., should be named "picramnine."

Dr. Hesse has been engaged upon an exhaustive investigation of the derivatives obtained from morphine by treatment of the base with acid anhydrides, using acetic and propionic anhydrides. He reports (*Annalen*, ccxxii., 203), that his experiments show that in morphine there are only two atoms of hydrogen which can be replaced by radicals of the fatty acid series,—such as acetyl or propionyl,—thus confirming previous statements that the base contains only two hydroxyl groups. But these two hydroxyl groups do not both stand in the same relation to the morphine, the hydrogen of one of them being replaceable by an acid radical and the other either by an acid or an alcohol radical It is to the latter hydroxyl that the phenol-like character of morphine is attributable.

In the new periodical, *The Asclepiad* (p. 91), there is an illustrated description of Mr. A. W. Blyth's cochineal test for lead in water. This consists in adding ten drops of a one per cent. solution of cochineal in proof spirit to an ounce of the suspected water, placed in a white porcelain dish. If the water be free from lead the cochineal colour will remain unaffected, but if it contain one part of lead in seven hundred thousand it will be changed to a purple pink, whilst with one part of lead in seventy thousand it will become purple blue. By a slip in the text one grain in ten gallons is represented as equal to one part in seven hundred.

The sophistication of quinine sulphate with a cinchonine salt, which occurred some time ago in Paris, has occasioned the issue by the French War Department of an official test for the purity of the samples of quinine sulphate that may be submitted to that department, and the test is an exemplification of the truism that a little knowledge is a dangerous thing. Among the nine tests that are given it is required that the sample shall be white, homogeneous and crystalline; and that when calcined it shall not leave a residue exceeding 25 centigrams per 100 grams (that is, 0·25 per cent.). It should not contain any quinidine, salicin or other foreign matters; its aqueous solution should be perfectly clear and alkaline to test-paper; moreover, it should consist of quinine, 76·25; sulphuric acid, 9·42; water driven off at 100°, 12·00; water combined at 100°, 2·33. Finally, the quantity of cinchonine admitted by tolerance should not exceed "two-hundredths." Apart from the other singularities in these requirements, no mention is made of cinchonidine, the alkaloid commonly occurring in samples of commercial quinine sulphate, and it is difficult to understand the reason of fixing the limit of water at 12 per cent.

According to Dr Hager (*Ph. Central.*, xxiv., 570), benzoate of soda prepared from "resin benzoic acid" (*i.e.* benzoic acid prepared from resin by the wet process) is said to be more active than the benzoate prepared from artificial acid. As a means to distinguish between the two, he recommends to dissolve 0·1 gram of the benzoate of sodium in 10 c.c. of water and add to the solution 20 drops of solution of potassium permanganate (presumably the P.G. volumetric solution, 1 gram in a litre). The resin benzoate causes no change of colour within an hour, whilst with the "artificial" benzoate the permanganate undergoes reduction within half an hour. The assumption that the term "resin acid" indicated the sublimed acid, which Dr. Hager says is incorrect, has given rise to some criticism of this test, marked by the acrimony that appears to be inseparable just now in Germany from any discussion referring to the action of potassium permanganate upon benzoic acid.

In a pamphlet issued by Messrs. Schering, of Berlin, which contains an interesting account of the experiments made by Dr. Cervello and others with paraldehyd, some surprise is expressed that notwithstanding the results obtained with this compound as a hypnotic it has not yet come more widely into use. This, it is thought probable, is due to some extent to the unfavourable impression caused sometimes by the use of an impure article, and mention is made of a preparation, labelled "pure paraldehyd," which not only contained acetaldehyd, boiling at 20° C., but was contaminated also with the poisonous amylaldehyd. The characters of pure paraldehyd, as given in this pamphlet, are that it should have a specific gravity of 0·998 at 15° C., boil at 124° C., solidify at 10° C., mix in all proportions with alcohol and ether and with 10 parts of water at 15° C. On account of its complete solubility in water, paraldehyd is said to be most conveniently administered in aqueous solution, with an addition of a suitable syrup.

A considerable amount of attention has been paid recently to the preparation of a "tasteless tannate of quinine," but a series of experiments made by Mr. C. E. Field (*Pharm. Record*, iv., 5), using solvents representing the gastric juice, as well as gastric juice obtained from a dog, have led him to the conclusion that as a remedy representing quinine the tannate is comparatively valueless in consequence of its insolubility. Further, when given to adults in doses of ten grains it failed to produce the usual effects of quinine.

In a paper contributed to the New York *Medical News*, Dr. Da Costa has published the result of observations made by him, following the administration of some salts of nickel in the treatment of certain nervous diseases, and has recommended the use of a syrup of nickel bromide. According to Mr. Genois (*Pharm. Record*, iv., 5) this syrup can be conveniently prepared by the direct combination of the elements and the addition of sugar to the solution obtained. He gives a formula for preparing it of a strength corresponding to five grains of the salt in each teaspoonful, which consists in mixing together 468 grains of bromine, 172 grains of granulated zinc and 16 fluid ounces of water, promoting the reaction by the aid of a very gentle heat, when it is completed adding 25 troy ounces of sugar, and after straining mixing with sufficient syrup to measure a quart.

In the *British Medical Journal* (Jan. 19, p. 103) Dr. G. C. Kingsbury recommends the use of chloral for persistent hiccough, a dose of 30 grains having proved sufficient to stop the hiccough after the patient had suffered incessantly from it for twelve days.

A few years ago Dr. Luton, of Rheims, stated that strychnia is the antidote for alcoholic intoxication, and that the presence of strychnia in alcoholic drink ought to be authorized by the Government. M. Dujardin Beaumetz contributed some interesting remarks on this subject at a meeting of the French Temperance Society, in which it was stated that strychnia had been found to combat the symptoms of drunkenness and also of acute delirium, but that it does not at all prevent or modify the condition of the organs injured by excessive drinking of alcohol (*Brit. Med. Journ.*, Jan. 19, p. 132).

It was lately proposed by M. A. Gerard, at the Academy of Sciences, to destroy by means of sulphuric acid the bodies of animals dying of virulent diseases; but M. Regnard (*Revue Medicale*, Dec. 1) now points out how easily bodies might be made away with by means of a liquid so readily procurable, and suggests that some restriction should be placed upon its sale. His experiments on dead newly born infants showed that the body entirely disappeared when digested with twice its weight of commercial sulphuric acid for twenty-six or thirty hours, leaving no trace except the presence of some fat, phosphoric acid and nitrogen (*Med. Times*, Jan. 5, p. 32). It by no means follows, however, that the bony structure of an adult would leave no traces or would dissolve so easily, as seems to be taken for granted.

Although numerous remedies have been proposed from time to time for the cure of hydrophobia, hardly any of them appear to have been the object of careful physiological experiment. Some months ago Professor Bouley communicated to the Academy of Medicine of Paris a case in which hydrophobia had been apparently cured by the administration of pilocarpine. The use of garlic in the same disease has also recently been revived. M. Gibier, desirous of ascertaining whether these drugs were of any real value, has submitted them to the test of careful experiments (*Comptes Rendus*, xcviii., p. 56), and has found that rats inoculated with the poison, in spite of being fed with a mixture of meat and garlic every day to the extent of 4 grams of garlic per day, succumbed to the disease in ten or thirteen days, even when their systems had been saturated with garlic by feeding on it a month previous to inoculation. Garlic, therefore, is neither a prophylactic nor an antidote to the poison. The same results followed the trial of hydrochlorate of pilocarpine as a remedy. The cats and rats experimented on died of hydrophobia, and the inoculation of the nervous matter produced the same disease in other subjects of experiment.

Dr. W. C. Gregg directs attention (*Brit. Med. Journ.*, Jan. 12, p. 56) to the great value of vinegar in *post-partum* hæmorrhage, a fact which cannot be too widely known, as vinegar is almost sure to be at hand and in such cases immediate action is required. He discovered its value by accident. He had ordered a wineglassful of brandy, and vinegar was administered by mistake; it had, however, the desired effect, the hæmorrhage ceasing immediately. Subsequent trials proved it to be superior to ergot in rapidity and certainty of action; so much so that it is not advisable to give it until after removal of the placenta.

The value of oil of hypericum for bedsores, as recommended by Dr. H. S. Snow, receives further confirmation from Mr. F. Clark, honorary consulting surgeon to the Leamington Provident Dispensary, who says he has used it with manifest advantage in severe cases. He adds that the oil requires exposure to the sun for three months to acquire the reddish brown tint. The name of the species of *Hypericum* from which the oil is derived is given in the *British Medical Journal* (January 5, p. 9) as "*Hypericum medium perforatum* which flowers in July." The name, however, will not be found in any work on British botany. *Hypericum perforatum* is a well-known plant, but why the word "*medium*" is used it is difficult to understand, as there is no variety of that name mentioned either in English botany or in De Candolle's 'Prodromus.' The remarks in Sowerby's 'English Botany,' ii., p. 146, indicates that *H. perforatum* is probably the plant intended, since it is stated under that species, "In country districts it is sometimes still used as a medicine, and oil in which the shoots or flowering tops have been steeped is sold by herbalists as oleum hyperiæ." Gerarde says of it, "a balsam prepared from it is a most precious remedie for deep wounds and those that are thoro the body, for the sinues that are prickt or any wound made with a venomed weapon. Dioscorides says: The seed drunke for the space of forty daies together cureth the sciatica and all aches that happen in the hips." The writer has known an ulcerated leg to be healed simply by the application of the bruised leaves of a shrubby garden species of *Hypericum*. Doubtless the properties of the plants of the genus are worth investigating, and may possibly, like the now disused willow bark and meadowsweet, be found to contain a substance as useful in other ways as the salicin contained in those two plants.

In continuation of the subject of the administration of anæsthetics, M. Paul Bert has recently communicated to the Paris Biological Society some details concerning his method of administering chloroform mixed with air (*Brit. Med. Journ.* Jan. 19, p. 132). He states that with such a mixture anæsthesia is reduced more slowly, but also more peacefully, the period of agitation being generally absent. The patient continues to sleep after the cessation of the inhalation, allowing of the dressing being effected painlessly, and upon waking is always calm and cheerful. As a rule a mixture in the proportion of eight grams of chloroform with one hundred litres of air is easily endured, and less chloroform is necessary than is generally required, from 15 to 20 grams sufficing for operations lasting as many minutes. It was also stated by M. Dubois, the principal of M. Bert's laboratory, that anæsthesia is more rapidly induced during alcoholic intoxication.

Dr. A. H. Hassall has continued his experiments on the best mode of administering inhalations, and in the *British Medical Journal* (January 12, p. 47) he shows that the atmosphere of a room can be impregnated with disinfecting agents to an extent and with a rapidity dependent on the surface exposed to diffusion and the vitality of the substance employed. Thus 616 grams of thymol melted in hot water in a dish having a superficies of 64 inches entirely disappeared in twelve hours, being exposed during that time to a temperature of 161·6° F. For the same reasons creasote sprinkled on a towel was found not to volatilize so quickly as when a towel was dipped in a solution of it; less surface being exposed to diffusion in the first case than in the latter.

A subject has been brought forward by Dr. Carter Moffat, which, interesting in itself, stands some risk of being brought into derision by absurd statements made in connection with it. The fact that the inhalation of some gases is followed by perceptible effects upon the *timbre* of the voice is well known, and the observation might be well worth following up from a musical point of view. But according to certain statements Dr. Moffat's alleged discovery was arrived at in a different way. Assuming that there was a connection between the fame of Italian vocalists and the atmospheric conditions of their native country, it is said that he made repeated analyses of the air and dew in different districts of Italy and found peroxide of hydrogen and free ammonia always present. He therefore attempted to imitate these conditions, and this it is claimed he is able to do by means of inhalations through an instrument which he calls an "ammoniaphone," described as containing an absorbent material saturated with peroxide of hydrogen combined with ammonia and other ingredients. This "portable artificial Italianized air" is credited with remarkable physiological properties, since, as the result of fourteen days' experiments, it is said to have caused an expansion of Dr. Moffat's chest half an inch, and to have converted his voice, which was previously weak, harsh and destitute of intonation, into a pure tenor of extraordinary range. Demonstrations of the effect of inhalations through the ammoniaphone have been given in connection with lectures delivered at Glasgow, and according to the *Evening News* "the results were highly satisfactory."

A patent has been taken out in Germany by Messrs. Vorster and Grüneberg, for a process for preparing what they term "dry sulphuric acid," which resembles one already followed in the preparation of dynamite. It consists in saturating dry and finely powdered "kieselguhr" with three or four times its weight of 66° sulphuric acid. The product, which, therefore, represents at least 75 per cent. of its weight of absolute acid, is said to retain the pulverulent form, and the advantage claimed is that in this condition it can be transported by land or sea in lead-coated sheet iron vessels without danger of breakage. When required for such purposes as petroleum refining, the manufacture of dynamite, or the production of carbonic acid gas for aerated waters, it is stated that the "dry" acid can be used without previous treatment, the finely divided condition in which it is present in the powder being indeed advantageous in some instances; but where necessary, the strong acid may again be obtained in the liquid condition by a systematic washing of the powder, the "kieselguhr" remaining unacted upon and fit for use in a fresh operation. The process can also be applied to the other mineral acids.

Some interesting details of comparative experiments as to the value of calcium chloride and strong sulphuric acid as exsiccating agents have been published by Dr. E. Fleischer (*Zeits. anal. Chemie*, xxiii., 33). In order to avoid repeated weighings to ascertain the point at which the weight became constant, Dr. Fleischer introduced a delicate hygrometer by Lambrecht, by which he was enabled to observe the point at which no further change took place. The results obtained seem to show that both in respect to rapidity and completeness of the dehydration effected calcium chloride is far inferior to sulphuric acid. The apparatus used was a bell-glass of 2266 c.c. capacity, ground to fit air-tight upon a glass plate, within the bell-glass being placed the hygrometer and a glass vessel an inch in height and half the diameter of the bell, to contain the hygroscopic material. When the glass dish was covered with 60 grams of fused calcium chloride, in pieces about the size of a hazel nut, and covered over with the bell-glass, the hygrometer, which at first showed 62 of relative moisture, or equal to 10 grams of water vapour per cubic metre of air, fell in two hours to 31°, four hours to 25°, in six hours to 21°, and then remained stationary; only an imperfect dehydration had been effected, therefore, in that time. When, however, the calcium chloride was replaced by 20 grams of concentrated sulphuric acid, the hygrometer, which at first stood at 67° fell in thirty-five minutes to 30°, in fifty-five minutes to 18°, and in one hundred and five minutes to 0°.

In a communication to the Royal Society (*Proceedings*, xxxv., 345), Dr. Tilden and Mr. Shenstone have given an account of some experiments made with the view of determining the solubility of salts in water at temperatures above the boiling point of water. The main conclusion arrived at is that solubility is directly related to fusibility. When salts usually crystallizing in the anhydrous state are written down in the order of their melting points, it is observed that increase of solubility consequent upon a rise of temperature above 100° C. is greatest in the most fusible, the others following regularly in order of their fusibility, and that the higher the melting point of a compound the more nearly does a curve representing its solubility at temperatures above 100° C. approach a straight line.

In a communication to *Nature* (Dec. 20 and 27) Mr. Barlow puts forward an ingenious theory as to the probable nature of the internal symmetry of crystals. Mr. Barlow is of opinion that in the atom-groupings of a molecule the several atoms occupy distinct portions of space and do not lose their individuality. He therefore first proceeds to inquire what number of very symmetrical arrangements of points or particles in space are possible. Of these he describes five, and he argues that every one of the various symmetrical forms presented by crystals can be shown to be consistent with the subsistence of an arrangement of the atoms of the crystallizing compound in one or other of these five kinds of symmetry at the time when crystallization begins. It is not meant by this that there are only five forms of crystallization; for although two of these kinds of symmetrical arrangement admit of no variation, in which compounds containing an equal number of atoms of two kinds have the atoms built up regularly, so that in one case each point is equidistant from the nearest eight points, and in the other equidistant from the nearest six points (cubic system), in the remaining three kinds, where the numbers of the dissimilar atoms in the molecule are unequal, a considerable amount of variation is possible in the arrangement of the third layer. Hence, whilst as a rule compounds consisting of an equal number of atoms of two kinds crystallize in cubes, in the case of water, where the dissimilar atoms are in the relation of 1 : 2, the arrangement of the atoms, according to the above theory, is capable of taking the form either of a six-sided prism or a rhombohedron.

Encouraged by his advance upon the results previously obtained by Messrs. Pictet and Cailletet, in the liquefaction of oxygen under the influence of the cold produced by the vaporization of liquid ethylene in a vacuum combined with pressure, M. Wroblewski has been pursuing his experiments upon the liquefaction and solidification of gases with some further success. He reports (*Comptes Rend.*, xcvii., 1553) that when a considerable quantity of liquid oxygen is caused to "boil" by the sudden removal of the pressure it does not solidify like carbonic acid, but leaves a crystalline residue at the bottom of the vessel, which disappears as the temperature commences to rise. The temperature at the moment of the formation of these crystals is estimated to be as low as – 186° C., and when liquefied nitrogen was submitted to this cold, by enclosing it in the vessel in which the oxygen was liquefied, and the pressure upon the nitrogen then slightly removed, it fell like snow, in crystals of a considerable size. In a subsequent communication (*Comptes Rendus*, xcviii., 149) M. Wroblewski states that hydrogen refrigerated by "boiling" oxygen is liquefied upon being released from pressure.

Last week, Professor Hughes read before the Institute of Mechanical Engineers an account of his further researches on the physical condition of iron and steel. In a previous paper (*Pharm. Journ.*, [3], xiii., 685), Professor Hughes stated his reasons, based upon the results of experiments with his induction balance, for believing that the molecules of soft iron, and even of hard drawn iron, are much less rigid as regards motion among themselves than the molecules of tempered steel. Since then he has continued his experiments and arrived at conclusions that he formulates as follows: (1) the magnetic capacity is directly proportional to the softness or molecular freedom; and (2) the resistance to a feeble external magnetizing force is directly as the hardness or molecular rigidity. Up to the present time mechanical tests as well as chemical analyses have failed to find any distinct line of demarcation between the numerous varieties of steel and iron, and this physical method appears to show that there is no such dividing line. But Professor Hughes is of opinion that by determining the magnetic capacity of a bar or wire of iron or steel a considerable amount of light may be thrown upon its homogeneity and other characteristics.

A "RENNET" FERMENT CONTAINED IN THE SEEDS OF WITHANIA COAGULANS.*

BY SHERIDAN LEA, M.A., TRINITY COLLEGE, CAMBRIDGE.

The Report of the Royal Gardens at Kew for 1881 contains abstracts of correspondence, in which it was pointed out that, in order to introduce a cheese-making industry in India, some vegetable substitute must be found for the ordinary animal rennet, since cheese made with the latter is unsaleable among the natives. In response to the above "Surgeon-Major Aitchison brought to the notice of the authorities at Kew that the fruit of *Puneeria*† *coagulans*, a shrub common in Afghanistan and Northern India, possesses the properties of coagulating milk;" and experiments showed that an aqueous extract of the seed-capsules of the above plant does somewhat rapidly coagulate milk.

I was recently requested to make some experiments on the seeds of *Withania* to determine whether they contain a definite ferment with the properties of ordinary rennet, and the applicability of such a ferment to cheese-making purposes.

The material supplied to me consisted of an agglomerated dry mass of seed-capsules and fragments of the stalks of the plant. When crushed in a mortar the whole crumbled down into a coarse powder, in which the seeds were for the most part liberated from the capsules. I picked out the larger pieces of stalk, sifted out the finer particles, chiefly earth and fragments of the capsules, and then by a further sifting I separated the seeds from the other larger particles. The seeds appeared to be each enveloped in a coating of resinous material, presumably the dried juice of the capsules in which they had ripened.

Taking equal weights of the seeds, I extracted them for twenty-four hours with equal volumes of (i) water, (ii) 5 per cent. sodic chloride, (iii) 2 per cent. hydrochloric acid, (iv) 3 per cent. sodic carbonate. Equal volumes of each of the above were added in an acid, alkaline, and neutral condition to equal volumes of milk, and heated in a water-bath at 38° C. The milk was rapidly coagulated by the salt and sodic carbonate extracts, much less rapidly by the other two; of the four, the salt extract was far the most rapid in its action. All subsequent experiments have shown that a 5 per cent. solution of sodic chloride is the most efficient in the extraction of the active principle from the seeds.

There is no doubt that the substance which possesses the coagulating power is a ferment closely resembling animal rennet.

I. A portion of the 5 per cent. sodic chloride extract loses its activity if boiled for a minute or two.

II. The active principle is soluble in glycerine, and can be extracted from the seeds by this means; the extract possesses strong coagulating powers even in small amounts.

III. Alcohol precipitates the ferment body from its solutions; and the precipitate, after washing with alcohol, may be dissolved up again without having lost its coagulating powers.

IV. The active principle of the seeds will cause the coagulation of milk when present in very small quantities, the addition of more of the ferment simply increasing the rapidity of the change.

V. The coagulation is not due to the formation of acid by the ferment. If some of the active extract be made neutral or alkaline and added to neutral milk, a normal clot is formed, and the reaction of the clot remains neutral or faintly alkaline.

VI. The clot formed by the action of the ferment is a true clot, resembling in appearance and properties that formed by animal rennet, and is not a mere precipitate.

Having thus determined the presence of a rennet

* Communicated by Professor M. Foster, Sec. R.S.—From the 'Proceedings of the Royal Society.'

† The genus *Puneeria* is now reduced by botanists to *Withania*.

ferment in the seeds, I endeavoured to prepare an active extract, which should be applicable for cheese-making purposes. All the extracts of the seeds are of a deep brown colour, and it appeared, therefore, in the first place, desirable to obtain less highly coloured, if not colourless, solutions, which should still be active. In this I have so far failed. The precipitate caused by alcohol carries down the chief part of the colouring-matter also, so that on being subsequently redissolved the solution is nearly as highly coloured as before the precipitation. The colour can be removed by using animal charcoal, but the ferment is at the same time destroyed. If all excess of charcoal is avoided and the solution is filtered at once, the filtrate is largely decolorized, but contains only traces of the ferment. Animal rennet is similarly removed by filtration through charcoal. The colour can be removed by the addition of very finely-powdered kaolin in a dry state, but, as before, the ferment activity is thereby destroyed. The same holds good of animal rennet. The colouring-matter is scarcely soluble in either ether or alcohol, so that no advantage is gained by a preliminary treatment with these before extraction with the salt solution. I have also endeavoured to get rid of the colour by treating the seeds as rapidly as possible with successive quantities of water before making the final extract. By using a centrifugal machine I was able to wash the seeds six or seven times with large volumes of water without their being exposed for any considerable time to the action of the water. Each portion of water was highly coloured and the seeds were thus freed from adherent colouring-matter. But, apart from the fact that some, though not much, ferment is thus lost, no special advantage is obtained, since the seeds are themselves coloured, and even after prolonged treatment with water the final extract is always of a dark brown colour.

In order to obviate the disadvantages of this colouring-matter, if disadvantage it is, I have found it best to prepare very concentrated active extracts of the purified seeds, so that it should only be necessary to add a very small quantity of the extract in order to coagulate the milk and obtain a colourless curd. This I have done by grinding the dry seeds very finely in a mill and extracting them for twenty-four hours with such a volume of 5 per cent. sodic chloride solution that the mass is still fluid after the absorption of water by the fragments of the seeds as they swell up. From this mass the fluid part may be readily separated by using a centrifugal machine (such as is used in sugar refining), and it can then be easily filtered through filter-paper; without the centrifugal machine the separation of the fluid from the residue of the seeds is tedious and imperfect, 40 grams of the seeds treated as above with 150 cubic centims. of 5 per cent. sodic chloride solution gave an extract of which 0·25 cubic centim. clotted 20 cubic centims. of milk in twenty-five minutes, and 0·1 cubic centim, clotted a similar portion of milk in one hour. When added in these proportions the curd formed is quite white. The presence of the colouring-matter is, however, perhaps on the whole unimportant, since even if a larger quantity of the ferment extract is added in order to obtain a very rapid coagulation the colouring matter is obtained chiefly in the whey, the curd being white.*

The question of preparing an extract which should be capable of being kept for a considerable time is perhaps of importance. Ordinary commercial rennet usually contains a large amount of sodic chloride and some alcohol. One specimen I analysed contained 19 per cent. of common salt, and 4 per cent. of alcohol. I have, therefore added to the 5 per cent. chloride extract mentioned above, enough salt to raise the percentage of this to 15 per cent., and also alcohol up to 4 per cent. The activity of the extract is not appreciably altered by this, and such a preparation corresponds very closely in activity with a commercial solution of animal rennet with which I compared it. The possibility of making extracts which may be expected to keep is thus indicated, but of course time alone will show whether the activity of the ferment is impaired to any important extent by such keeping.

I may add in conclusion that I have coagulated a considerable volume of milk with an extract such as I have described, and prepared a cheese from the curds. I have also given a portion of the extract to a professional cheese-maker who has used it as a substitute for animal rennet in the preparation of a cheese. The product thus obtained, and the statements of the person who has made the experiment for me, lead me to suppose that extracts of the seeds of *Withania* can be used as an adequate and successful substitute for animal rennet.

* It is extremely probable that some stage in the growth or ripening of the seeds of *Withania* might be found at which the development of colouring-matter is slight, while at the same time the ferment is present in considerable quantity.

THE HYPOPHOSPHITES WITHOUT SYRUP.*

Dr. G. S. Gerhard recommends the following formula: —℞ Calcii hypophosph., Potassii hypophosph., Sodii hypophosph., āā gr. j; Quiniæ hypophosph., Mangan. hypophosph., āā gr. $\frac{1}{4}$; Ferri hypophosph., gr. $\frac{1}{2}$; Strychniæ hypophosph., gr. $\frac{1}{120}$; Glycerini, ♏iij; Liq. acid. hyposulph., ♏ij; Aq., ad fl. ℥j. The addition of a definite amount of hyposulphurous acid prevents the precipitation of at least two of the salts (those of iron and manganese). The solution is clear, slightly fluorescent and pleasantly acid. This formula is certainly an improvement on the ordinary syrups, the excess of sugar in which often decreases the appetite and deranges digestion. Two minims of acid. phosphoric. dilut., B.P., if substituted for the hyposulphurous acid in the above formula, appear to be equally efficacious in preventing precipitation. If the iron and manganese be omitted, a few drops of dilute hydrobromic acid serve to maintain the other ingredients in clear and permanent solution.

THE PRESS ON THE SALE OF POISONS.

From the Saturday Review, *January 26.*

It is high time that some steps should be taken to amend the present state of the law on poisons. Many of us have been long under the happy delusion that the Act of 1868 was quite sufficient for the purpose of protecting the public. But, owing to defects in its wording, it is easily and systematically evaded, and a recent decision of the House of Lords has practically abrogated one of its principal provisions. Not only are poisons openly sold by unqualified people, but so are drugs of other kinds so inferior in quality as either to be useless or else actually deleterious. Nearly all drugs are more or less poisonous at best, but bad drugs are doubly so; and it is difficult even by legislation to protect people who are not learned in their properties. They are absolutely at the mercy of the vendors, who may call any substance by the name of a medicine, and the buyer has no means of ascertaining the truth or falsehood of the description. This view is borne out by many recent examples, and is put forward prominently by some of the most eminent members of the Pharmaceutical Society. In a recent address Dr. Attfield, the President [of the British Pharmaceutical Conference], called public attention to it, and asserted that the present condition of things is worse than before the Act of 1868. The Act prohibited any one from taking the title of "chemist and druggist," and practising under it, without having qualified at an examination, and being placed on the State Register. But by some oversight no provision was made for the case of drug-sellers who did not take the title of "chemist," and the result is that a grocer may keep medicines, and sell them as if they were food or chandlery. Nay more; though the adulteration of food is forbidden, and the buyer is able to judge for himself, with drugs he cannot judge, and the State does practically

* From the *Phil. Med. Times,* November 3, 1883. Reprinted from the *Medical Times,* January 26, 1884.

nothing for his protection. True, the State forbids the sale of ostensible poisons, or rather draws a line between some poisons and others; but even this provision is easily evaded. Under cover of a patent-medicine stamp such poisons as opium, laudanum, and morphia are constantly sold by grocers or general dealers. Soothing syrups alone, which may be bought everywhere, are accountable for a vast number of deaths, and bring up infant mortality, especially in London, to its present appalling figure. It is asserted that in some districts in which opium is largely sold it is put up in regular packets, labelled "Sedative Powder," or some such name, sealed with a $1\frac{1}{2}d.$ stamp, and sold by any one who holds a patent medicine licence. The respectable chemists refuse, as they are bound to do, to sell deadly poisons in dangerous quantities to any stray customer; but it is notorious that in other places—wherever, in short, an unauthorized chemist carries on his trade—the merest formality, such as signing a name, suffices, and the poison is sold, no questions being asked. This is, of course, the strong point in the complaints recently made by the pharmaceutists. It remains to be seen how far they are justified in their protests; but, admitting that the will of the nation was revealed in the Act of 1868, it is difficult to avoid the conclusion that something more must now be done to give it effect.

Oddly enough, the whole question is complicated by another, with which at first sight no one would think it had any connection whatever. We hear enough about the enormities of co-operative stores from tradesmen whose former profits are now cut down; and for the most part we turn a deaf ear to their complaints. The stores are a convenience; and if the small tradesman is unsuited to the spirit of the times, he must go, as other people have had to go in the course of ages. But when the chemists complain of the stores, their case is wholly different. Their complaint may be in part selfish, like that of the grocers, but it is also in part, and that the larger part, for the public good. Co-operative stores have peculiar advantages in the sale of drugs. If they are managed by seven owners or more, they are absolutely in this particular beyond the reach of the Act. According to the recent decisions, a co-operative store may even sell poisons "if no registered assistant is employed," thus simply reversing the obvious meaning and intention, though not, of course, the letter, of the Act. But even as regards single shopkeepers it is inoperative. Professor Attfield gives particulars of many cases, described by his correspondents, in which most drugs are openly sold, and a few in which "not only ordinary poisons, but the scheduled poisons," are also to be had, but under certain bonds of secresy. The druggist who has studied and has passed his examinations has no chance with the unqualified grocer or the storekeepers. They can both undersell him and make capital by pointing out what an extortioner he is. We have knowledge of a certain virulent and deadly poison which can be bought wholesale at about $4d.$ the pound, but which a chemist retails at about $4s.$ the ounce, and rightly so. But the unqualified druggist sells it at a moderate price, if he sells it at all, and perhaps binds his customer to secresy as well, thus involving him in a conspiracy to break the law. A single grain of that particular poison has frequently produced death, yet in many different households enough may be met with to poison a regiment. There is a law regarding another poison which seems to be very seldom observed. Sulphuric acid is one of the most easily obtained, and one of the most destructive agencies known of its kind. Hardly a day passes but we read some case of "vitriol throwing." Vitriol being practically colourless may easily escape notice until too late. The public are partially protected against arsenic by its being, when sold in small quantities, coloured with indigo. The rule is frequently evaded, but it should be enforced and applied to sulphuric acid also. Dr. Attfield, in his speech at Southport, was necessarily more immediately concerned with the honour and the standing of his professional brethren than with the convenience or safety of the public; yet it is remarkable how completely the two were shown to be interdependent; and no one can doubt that a lowering in the standing and character of the dispensers of drugs must result, not only in loss to the qualified chemist, but in still more disastrous consequences to the consumer.

The quantity of medicine now prescribed and used is very much less than formerly. In 1830, for example, at St. George's Hospital the cost for every in-patient's medicine was 16*s.* 5*d.* In 1880 it was less than half. Partly this is owing, no doubt, to a cheapening in druggists' wares; but it is also due to the alteration in medical practice. Leeches, for instance, which used to be so frequent, are now seldom seen. Blisters are characterized by some eminent physicians as mere useless torture. Instead of a costly black draught, we have a few pence worth of some pleasant effervescing mixture. The whole aspect of medicine-taking has been altered. Ten years ago, even, a new-born baby received a dose calculated to injure it for life; and twenty years ago all children had medicine once a week, whether they wanted it or not. Mrs. Squeers with her brimstone-and-treacle was no exaggeration. Such scenes as Dickens describes in 'Nicholas Nickleby' were common not only in such places of Dotheboys Hall, but in every large boarding-school, when many of us were almost grown up. At the present day, therefore, the apothecary cannot expect the same sale for his simples as formerly; but the public is not on that account the less justified in demanding greater security and greater excellence. The patent medicine system is liable to all kinds of abuses, and should be abandoned. It brings in a trumpery sum, and is a legalization of quackery. The very name of "patent medicine" is a lie. We have by the abortive Act of 1868 acknowledged that something should be done. The principle is admitted. Of course before 1868 it was open to any one to object that it is "grandmotherly legislation" to interfere with the sale of drugs. But no such argument will hold now, except perhaps with such old ladies and their friends as supported Mr. Stansfeld on a recent occasion. The right of the free-born Briton to make a beast of himself with drink is seriously called in question; but before proceeding to limit the sale of such a comparatively innocuous compound as beer or gin we should endeavour to protect ourselves both from adulterated drugs and also from poisons. Every daily paper contains stories of poisoning. Three have appeared this very week, each of which could have been prevented by proper regulations. A prisoner is poisoned in the very hands of the police. A child is poisoned by a quack. A husband obliterates features he once professed to admire by the use of a little sulphuric acid. The list might be indefinitely prolonged. Where did all these people obtain their poisons? It would be well worth the while of the Pharmaceutical Society to make a list of such cases for say three months, and to ascertain in each case if possible where the poison was bought. If it should be found that all or a majority came from stores, grocers, and other unauthorized dealers in drugs, the case put by Dr. Attfield would be immensely strengthened. It is perfectly true that legislation can hardly be evoked at the present day—in the so-called "Nineteenth Century," as it has recently been described—for the prolongation or strengthening of a monopoly; but, if the chemists can show that it is owing to the unauthorized sales of drugs and poisons that these shocking tragedies, so far from being less common than before 1868, are actually more common and on the increase, they may come to Parliament with a very good case; and when some of the much less important measures to which the present Government has pledged itself to please its Radical supporters have been disposed of, a Bill in extension, explanation, or confirmation of that of 1868 may be passed, and English people may be protected like Frenchmen, Germans, Italians—indeed almost all nations—against the occurrence of such horrors as we have mentioned.

THE SALE OF NARCOTICS.

THE report, on another page, of the proceedings in connection with an inquest held at Moss Bank, near St. Helens, supplies a vivid illustration of the evil results attending a custom widely prevalent in the manufacturing districts, and also shows how ready local authorities are to imitate the waggoner of the classics and invoke extraneous help instead of using the power they already possess to do the work that lies before them. The death, which was the occasion of the inquiry, was, probably, typical of many that take place continually, the principal difference being that now and then one—like that at Moss Bank—attracts passing attention through becoming the subject of an investigation before a coroner; but even then, after a certain amount of more or less wise official and volunteered commentary, it passes into oblivion. In the case under notice, a child, nine years old, being sick and purged, was dosed by his mother with an ounce of a compound called "Indian tincture," which she had purchased from a grocer. As to the nature of the compound, or the quantity that could be safely administered to a child, both buyer and seller appear to have been profoundly ignorant; the latter ingenuously saying that he had sold the compound for five or six years in the state in which he had received it, and that when asked by the buyer whether half an ounce would be too much for a child, he had replied that he did not know. The posological demonstration followed, however, in due course; but as it was made upon a poor creature not protected by an analogue of the Vivisection Act, it has involved no punishment upon the originators, beyond the very problematic quantity resulting from twinges of conscience. The mother having administered the medicine went out, hoping, no doubt, that before her return it would bring relief from the vomiting and purging. And so it did, though not in the way desired; for when she came home the child was comatose, and a quarter of an hour afterwards it lay dead in her lap, the victim, in the opinion of the medical practitioner who was called in, of narcotic poisoning.

In consequence of the nature of the evidence given at the inquest, the Coroner ordered an analysis to be made of the contents of the stomach as well as of a sample of the "Indian tincture," and the report of Dr. CAMPBELL BROWN is instructive. He found the tincture to contain about 30 per cent. of its volume of methylated spirit, a small quantity of ether, sugar, extractive and two kinds of resin. One of these resins had been derived from capsicum, the other is conjectured to have been the resin of *Cannabis Indica*, apparently upon the grounds that this resin is capable of producing symptoms similar to those observed in the child. But we think that the influence of the doubtful resin may be safely ignored, for although Messrs. SMITH found that the two-thirds of a grain of Indian hemp resin acted as a powerful narcotic,* yet since the total quantity found of the two resins together only amounted to 0·012 per cent. of the tincture, and of this the greater part was capsicum resin, the amount of the other resin contained in the ounce of tincture would only have been a small fraction of half a grain. The symptoms would seem to find a sufficient explanation in the fact that the child, exhausted by vomiting and purging, had swallowed a third of an ounce of methylated spirit, besides a quantity of ether. Upon inquiry it was found that the mixture had been supplied wholesale to the grocer by a "licensed patent medicine dealer," and that the stock bottle bore a label in which the preparation was vaunted as "the only original highly medicated tincture for coughs, colds, bowel complaints, etc."

We are thus brought face to face with a traffic that has, according to the evidence, been carried on during five or six years at least under conditions that involved continuous breaches of two highly penal laws, though neither of these happened to be the Pharmacy Act, as the Coroner appeared to suppose. In the first place the use of methylated spirit in the preparation of any article capable of being used internally as a medicine is an offence under the Spirits Act, punishable with a fine of one hundred pounds; in the second place the sale of a preparation recommended on a label or in any way by public advertisement as a remedy for the cure or relief of any disorder, unless the seller shall hold a licence and the thing sold shall bear a stamp of value in proportion to the price for which it is sold, is an offence rendering the seller liable to a penalty of ten pounds for each sale. It must not be understood, however, that we in any way intend to convey approval of the sale of compounds containing poisonous substances under the cover of the Medicine Stamp and Licence Acts, or that conformity with these Acts is any sufficient guarantee for the public safety in such cases. But, however this may be, if the proper authorities under existing circumstances did their duty the penalties recoverable under these Acts would be equal to any profit that could be derived from this trade, and the sale of probably more than one deleterious preparation would be thus stopped. The statistics quoted by the Coroner as to

* *Pharmaceutical Journal*, [1], vi., 172.

the extent to which the trade in this class of preparations is carried on in the St. Helens district are hardly surprising to those who have any knowledge of the subject, and we notice with satisfaction the moderation of his statement, as compared with what is occasionally asserted, that he only believes that some of them contain opium. There is no doubt many of these preparations put forward more or less ostensibly as narcotics are carefully kept outside the application of the Pharmacy Act, notwithstanding the fact that the names they bear and the statements put forward in respect to them may suggest, to those competent to judge, that they may contain a scheduled poison. Probably with respect to a large number of them the provisions of the Sale of Food and Drugs Act or of the Excise Acts would be more applicable for their control as those of the Pharmacy Act. When, however, the police authorities are in possession, as they are frequently said to be, of certain information that preparations of opium or any other scheduled poison are being sold indiscriminately by shopkeepers, it undoubtedly becomes their duty to put in force the provision of the seventeenth section of the Pharmacy Act, which relates to labelling, which would also facilitate proceedings under the section that restricts the right of selling such poisons to qualified persons.

On the occasion of an inquest held recently at Eastbourne, as has already been mentioned, the Coroner refused to admit that a pharmaceutical chemist actually engaged in business was exempt from serving as a juror on an inquest, and intimated that he intended in future to enforce his opinion, if necessary, by means of a fine. We understand however, that, acting under the instructions of the President of the Pharmaceutical Society, the Solicitor has brought under the notice of the Coroner the specially inclusive words of the Act in relation to the exemption of pharmaceutical chemists, and that there is reason to hope the threatened contingency will not arise. Meanwhile, should any pharmaceutical chemist be summoned to serve on a coroner's jury it is desirable that he should at once put himself in communication with the Secretary. Whilst referring to this subject we may remark that it is important to remember that the exemption is not a personal privilege and should not be claimed as such, but is a condition imposed by the Legislature for the protection and safety of the public at large.

* * *

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, the 6th inst., at 8.30 p.m. On that occasion Messrs. Dunstan and Short will continue their Report on the Pharmaceutical Preparations of Nux-Vomica, dealing with the Preparation of a Standard Extract and of a Standard Tincture of Nux-Vomica. There will also be a paper on "The Estimation of the Alkaloids in the Root of *Atropa Belladonna*," by Messrs. Dunstan and F. Ransom, and one on "A Sample of Sophisticated Oil of Turpentine," by Mr. Boverton Redwood.

The *British Medical Journal* says it is understood that it is the intention of the Government to re-introduce the Medical Bill of last session with certain modifications, and that it is not probable that it will be again allowed to drop.

* * *

The past week has seen the issue of the first part of the new English Dictionary that was projected in 1857, by the Philological Society. Since that time hundreds of volunteers in Great Britain and the United States, as well as in other countries, have been working assiduously in the compilation and arrangement of materials, and the work is now being printed under the editorship of Dr. J. A. H. Murray, the President of the Philological Society, at the Clarendon Press, Oxford. The size of the work, which it is estimated will extend to six volumes of fourteen hundred quarto pages, will put it beyond the reach of more than a comparatively few private individuals, but there can be no doubt that it should be included in every library of any pretension. It promises to be a most valuable work of reference, and some idea may be formed of the wide range of literature that has been ransacked for words and quotations illustrative of their history and meaning from the fact that the complete series of the *Philosophical Transactions* from the year 1665 has been laid under contribution.

* * *

The interesting memoir on Kolas, by Messrs. Heckel and Schlagdenhauffen, an abstract of which appeared in last week's Journal, furnishes a fresh illustration of the desirability that investigators should make themselves acquainted with the existing literature of any subject they are working upon. It has been brought under our notice that the plant yielding "bitter kola," which those authors supposed themselves to be the first to identify, was identified as a species of *Garcinia* by Dr. Maxwell T. Masters eight years ago, and was partly described and the fruit figured by him in the *Journal of Botany* for March, 1875.

* * *

A fortnight since the *Medical Press and Circular* quoted from a German source a "well-found story" about the etymology of the word "charlatan," according to which it originated in connection with a Paris doctor, named Latan, who took to driving through the streets—crying his wares and looking out for patients—on a one-horse waggon (*char*). This is said to have given rise to the phrase, "Voilà le char de Latan," afterwards abbreviated into "charlatan." A correspondent in the following number, however, upsets this ingenious rendering by pointing out that the word is related to the Italian *ciarlare*, to prate, and *ciarlatano*, a quack.

* * *

We learn from the Barcelona *Enciclopedia Médico-Farmacéutica* that a committee of delegates of the pharmacists in the Spanish capital has recently presented a memorandum to the Governor of Madrid, pointing out certain abuses that exist to the injury of the public health, such as the distribution of globules by homœopaths to their clients, the sale of dosimetric granules, medical consultations in pharmacies and drug stores, the existence of pharmacies owned by unqualified persons, and other objectionable practices not unknown to pharmacists in our own country.

The endorsement of nostrums by leaders in medical and other branches of science in this country has on different occasions found varying explanations; but we doubt whether any of them has been so suggestive of the impudent side of smart advertising as one that has been communicated to the New York *Medical Gazette* by Professor Hamilton. The Professor, having seen a circular issued by a wine dealer, in which his name appeared as recommending certain wines, writes to say that some time since the wine dealer brought to him an album and laying it open before him asked him to add his name to those of other members of the medical profession which it contained and that he complied. But he protests that if the album contained, as he is now informed it did, recommendations of any wines, he was not aware of the fact. The *Medical News* asks, what more urgent plea could be presented for the abolition of the unprofessional habit of lending names to promote the interests of dealers in wines and nostrums?

* * *

The energetic Director of Public Gardens and Plantations in Jamaica, Mr. D. Morris, appears to have taken advantage of a recent vacation trip to collect a number of seeds and plants of economic importance, with a view to attempting their cultivation in the island. Among those obtained from Kew were a fine well-grown set of *Cinchona Ledgeriana* plants, as well as specimens of *C. caloptera* and *C. Calisaya*, var. *Josephiana*; a good strong scammony plant (*Convolvulus Scammonia*), which it is intended to attempt to cultivate in the hills; a plant of *Aloe Socotrina* and one of *A. Perryi*; this last mentioned, however, has not survived the voyage. Other plants obtained were the *Garcinia Mangostana*, *Quillaia Saponaria*, *Piper methysticum* (kava-kava), *Olea Europæa*, *Quercus Suber* and *Dracæna Draco*. Since his return also, a pot has been received from Kew containing about fifty plants of *Dracæna Cinnabari*, the species which, acccording to Professor Bayley Balfour (see before, p. 372), yields the true dragon's blood, as collected in the island of Socotra, referred to by Pliny and other old authors.

* * *

According to a comparison contained in a German official report the extent of the utilization of the post office as a means of communication by people of different European nationalities is represented by the following figures, which show the number of letters, post cards, etc., sent anually per head of population according to the returns for the year 1882 or the latest previous year for which a return had been made:—Great Britain, 52·5; Switzerland, 49·8; Belgium, 42; France, 35·3; Netherlands, 32·6; Germany, 31·8; Denmark, 30·6; Luxemburg, 23·1; Austria, 17·4; Sweden, 14·8; Norway, 14; Italy, 11·1; Hungary, 9·4; Spain, 7·1; Portugal, 6·9; Greece, 3·6; Russia, including Poland, 2·9; Roumania, 2; Servia, 0·7; Bulgaria, 0·5. In respect to the gross amount of business transacted by the Post Office Department, the United Kingdom ranks first, Germany second and France third.

* * *

In the earlier business days of the late Professor Holloway he appears not to have been averse to advising individuals upon the treatment of their particular complaints, and for this purpose he kept a printed form with blanks that were filled in according to circumstances. A quotation from the first paragraph of one of these forms, as filled in for a consultant in 1846 (the written words being printed in italics), may interest some of our readers and illustrate one method of creating a demand for specialties. The sentence runs, "I would recommend *eight* of my pills to be taken night and morning for the first *fifteen* days, *ten* night and morning for the following *thirty* days, and *twelve* night and morning might be taken after that time for about *thirty* days longer, or until such time as a perfect cure might be effected." The prescription, therefore, provided for the consumption of 1560, or 130 dozen pills. There was also a general direction to "rub plenty of my ointment into your chest night and morning, as effectually as forcing salt into meat."

* * *

The Paris correspondent of the *Lancet* states that after a service of more than a half a century as Director of the Gobelins manufactory, M. Chevreul has been placed on the retired list. In consideration of his great services the illustrious chemist has been allowed to retain the full salary; but such is the wonderful juvenility of which he appears conscious that although only wanting two years to become a centenarian he is said to resent his retirement as premature.

* * *

The proposal for the more frequent appearance of the *Archiv der Pharmacie*, the organ of the German Pharmaceutical Association, is being carried into effect, and the new volume commences with the issue of fortnightly parts, which are to consist of from thirty-two to forty-eight pages each.

* * *

In the case of Chave and Jackson *v.* Kitson heard last week in the Chancery Division of the High Court of Justice, before Mr. Justice Kay, a perpetual injunction was granted against the defendant in respect to the use of the registered trade mark "Celandine" claimed by the plaintiffs.

* * *

The Third Junior Pharmacy Ball is to be held at Willis's Rooms on Wednesday next. The Honorary Secretary is the gentleman who has so ably managed affairs in the two previous years, Mr. W. H. Kerr, 30, Conduit Street, W.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, February 7, at 8 p.m., when a "Note on Crystallized Phosphoric Acid" will be read by Mr. P. L. Huskisson, and the Reporter upon Physics, Mr. H. Allen, B.Sc., will make a report upon "Holtz's Electrical Machine and its Modifications," which will be illustrated by experiments.

* * *

The papers to be read at the meeting of the Chemical Society on Thursday next will be, "On the Influence of the Temperature of Distillation on the Composition of Coal Gas," by Mr. L. T. Wright; and "Researches on Secondary and Tertiary Azo-Compounds: No. II.," by Mr. R. Meldola.

* * *

A meeting of the London Section of the Society of Chemical Industry will be held in the rooms of the Chemical Society, Burlington House, on Monday next, at 8 p.m., when papers will be read—(1) "On the Disposal of Sewage Sludge;" (2) "On the Porter-Clark Process for the Purification of Water;" (3) "On Some Technological Applications of Kieselguhr."

Transactions of the Pharmaceutical Society.

EXAMINATION IN EDINBURGH.

January 22, 23 *and* 24, 1884.

Present on each day—Messrs. Baildon, Clark, Gibson, Gilmour, Maben, Nesbit and Stephenson.

Professor Maclagan was present on the 22nd and 23rd on behalf of the Privy Council.

MINOR EXAMINATION.

22*nd.*—*Fourteen* candidates were examined. *Six* failed. The undermentioned *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barratt, William ....King's Lynn.
Black, James Watson ....Aberdeen.
Borthwick, Robert Waddell ...Bathgate.
Cairns, John ....Kelso.
Campbell, Charles...................Manchester.
Coats, John Thomson ....Edinburgh.
Cumberbirch, William............Wilmslow.
Drummond, Robert Gordon ...Broughty Ferry.

23*rd.*—*Fourteen* candidates were examined. *Four* failed. The undermentioned *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Blackburn, Albert Ed. Henry...Eccles.
Findlay, James.....................Glasgow.
Flett, Arthur ....Edinburgh.
Graham, Robert ....Langholm.
Hays, Richd. Tanner Orchard...Cirencester.
Hood, Thomas ....Leith.
Jack, James ....Arbroath.
Macintosh, John ....Edinburgh.
Mackay, Alexander ....Inverness.
Rennie, William ....Dumbarton.

24*th.*—*Thirteen* candidates were examined. *Four* failed. The undermentioned *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Miller, Alexander Sutherland...Edinburgh.
Mitchell, William Kirkpatrick...Wigton.
Morris, John Hall ....Bolton.
Parry, Richard ....Liverpool.
Patterson, David ....Bolton.
Percival, Thomas ....Falkirk.
Scott, Samuel ....Glasgow.
Shairp, William ....Glasgow.
Steward, Josiah William.........Bridgnorth.

PRELIMINARY EXAMINATION.

A meeting of the Board of Examiners for England and Wales was held on Wednesday, January 30, 1884.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificate of the College of Preceptors.

Hughes, David Thomas ....Carnarvon.

Certificates of the University of Cambridge.

Cox, Charles Earnshaw ....Doncaster.
Ralling, Ernest Lewis............Colchester.
Sangers, Edgar Arthur ....London.

Certificates of the University of Oxford.

Atherton Henry Charles.........Tunbridge Wells.
Jackson, Frederick ....Manchester.

The following report of the College of Preceptors on the examination held on January 8 was received:—

Two hundred and seventy-eight candidated had presented themselves for examination, of whom *one hundred and fifty-one* had failed. The following *one hundred and twenty-seven* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically.)

Acutt, Frank Edward ....Wincanton.
Adams, Anthony Allan ....Salcombe.
Agar, Robert Langbourne ......Bridport.
Alford, Herbert Joseph ....Low Moor.
Allan, David..........................Gorebridge.
Andrew, John Herbert ....Oldham.
Aspden, Henry ....Over Darwen.
Baxter, Gilbert.......................Blackburn.
Bell, John Renwick.................Newcastle-on-Tyne.
Bethune, Andrew Wright ......Lochgelly.
Boe, John Alexander ....Edinburgh.
Bowie, Alexander...................Kincardine.
Brazil, James Joseph ....Monkwearmouth.
Brittain, Florence...................Birmingham.
Brown, Arthur Miller ....West Malvern.
Brown, George Hy. Allan ......Liverpool.
Brown, Thomas ....Hayes.
Burden, Chas. Henry Brown ...Bude.
Callam, William Eggleton ......Ilford.
Cameron, John ....Aberfeldy.
Capon, Henry Charles............London.
Cartwright, Benjamin ....Glasgow.
Chappell, Charles Creswell......Bromsgrove.
Chatterton, Joseph Owen ......Stockport.
Cherrett, Ernest Robert ....West Hartlepool.
Clarke, William Ernest ....Aberystwith.
Clayton, William Arthur..........Sheffield.
Cleghorn, James ....London.
Cockburn, Charles Taylor ......Glasgow.
Cole, John Frederick ....Worcester.
Copp, William Risdon.............Southampton.
Couzens, Albert E. ....Westbury, Wilts.
Cranstone, Ernest Haughton ...Hemel Hempstead.
Dewar, Daniel ....Stirling.
Dunlop, Thomas William ....Berwick-on-Tweed.
Durant, William James ....Crewe.
Eastwood, Frederick Allen......Rochdale.
Eastwood, Horace ....Milnsbridge.
Eatough, Nicholas William......Blackburn.
Edwards, Richard ....Shrewsbury.
Emerson, Richd. Wm. James...Hull.
Evans, Joshua William ....Llandyssul.
Evans, Thomas Henry............Llanelly.
Ferguson, Joseph Johnston......Southampton.
Fish, Benjamin, jun. ....Barrow-in-Furness.
Floyd, Joseph Arthur.............Alcester.
Ford, Arthur Miller................Glasgow.
Ford, James ....Montrose.
Foster, Edgar Denney.............Rugby.
Fraser, Archibald Morrison ...Glasgow.
Furness, Alexander Scott ....Edinburgh.
Gibson, George Wood ....Whitby.
Gibson, William Thomas..........Collingham.
Goddard, Saml. Hy. Carter ...Southport.
Grassick, Alexander ....Aberdeen.
Griffiths, William Robert ......Clynderwen.
Hall, Sidney Charles ....Newark.
Hardy. Robert ....Edinburgh.
Heap, Alfred.......................... Kendal.
Heaton, George Edward.........London.
Heaton, Thomas ....Batley.
Hender, Walter Coad ....Plymouth.
Hepton, John Cussons............Prescot.
Higson, John Russel...............Ruthin.
Hoare, William Richard.........Cheltenham.
Hornby, Arthur Smith ....Easingwold.
Howell, Albert.......................Warminster.
Jeeves, Henry ....Brighton.
Jones, William.......................Holyhead.
Joyce, Leonard.......................Boston.
Kelland, Richard ....Banwell.
Kendall, George William ......Rawdon.

Kennish, Joseph ....Whitehaven.
Kidd, George Thomas ....Stowmarket.
Kimber, Mary Jane...............London.
King, Arthur Hill ....Maldon.
Lacey, Thomas ....Ketton.
Laycock, William Frederick ...Lowton.
Leaper, John Shirley ....Spalding.
Le Gros, Alfred Joshua ....Jersey.
Lenton, Joseph........................Hastings.
Lloyd, James Herbert............Leicester.
Lyne, Walter Henry ....Grantham.
McClement, Thomas ....Penmaenmawr.
McLeod, William G. ....Nairn.
Madge, Herbert Abraham ....Ottery St. Mary.
Martin, John..........................St. Stythians.
Merrick, Wm. Stephen Nickels.Exeter.
Mills, George ....Southsea.
Mills, Herbert Henry ....Peterborough.
Morgan, James Gilbert ....Leamington.
Muir, George McCartney ......Cumnock.
Newman, Richard Seymour ...Hanley.
Ogilwy, Thomas William.........Windsor.
Orme, William Charles ....Atherstone.
Palmer, David Henry ....Peterborough.
Park, Frederick ....Tynemouth.
Perry, William Arthur ....Hitchin.
Pollard, Walter Henry ....Reading.
Prentice, Bertram ....Edinburgh.
Robertson, George ....Bridge of Allan.
Robinson, Joseph.................. Sunderland.
Senior, George ....Llanfairfechan.
Simpson, Frederick Charles ...Pershore.
Slinn, Harry Edwin ....Burton-on-Trent.
Smith, Edward Charles H.......Hull.
Smith, Kate Love .... Glasgow.
Smith, Robert William ....Edinburgh.
Stead, John Christopher ....Weston-super-Mare.
Stent, Frederick Richard ......Bath.
Stockdale, Richard ....Skipton-in-Craven.
Sturton, Frederick ....Peterborough.
Thornhill, Ernest ....Brighton.
Timmins, Albert ....Kidderminster.
Weatherby, Samuel MawdesleyBurslem.
White, James Leslie ....Edinburgh.
White, William John ....Edinburgh.
Widdowson, George William ...Leicester.
Wilkinson, Jacob Hardy.........Wibsey.
Williams, Cuthbert ....Leicester.
Williams, William ....St. Clears.
Wilson, George Alexander ....Aberdeen.
Winfield, George Fredk. ....Birmingham.
Woodington, Herbert ....Bristol.
Woolley, Edward James.........Manchester.
Wyatt, Alvan Lovell ....Stourbridge.
Wyllie, Harry Boak...............Kinghorn.

"College of Preceptors,
"Incorporated by Royal Charter.
"42, Queen Square, London, W.C.
"28 *January*, 1884.

"Dear Sir,—I send you herewith the copy of a short report made by the examiner on the recent Preliminary examination, supplementing the statement of marks forwarded to you to-day. "I am, dear Sir,
"Yours faithfully,
"C. R. Hodgson,
"E. Bremridge, Esq. "*Secretary.*"

"At the examination held in January, 1884, 278 candidates presented themselves at 36 centres with the following result:—

Passed 127 or about $45\frac{5}{7}$ per cent.
Failed 151 or about $54\frac{2}{7}$ per cent.

"Of the 151 who failed 78 failed in one subject only; 55 in two subjects; and 16 in all three subjects. Two candidates passed in the three subjects, but failed to obtain the required total.

"LATIN.

"Only 8 candidates brought up the 'Virgil,' and of these 6 passed the examination; of the other two 1 failed in Latin. In this subject an improvement has been steadily going on for some time past, especially in the answers to grammatical questions. The translation from the Latin is given very accurately in the large majority of cases, but very few indeed translate correctly into Latin the simple English sentences given.

"ARITHMETIC.

"This is still the 'plucking' subject. Of the 78 who failed in one subject only no fewer than 65 failed in this. Notwithstanding the special instruction in the Regulations, some of the candidates show no acquaintance with the metric system, and ignore the questions requiring for their solution a knowledge of it. To emphasize the importance of this branch of the subject, it would be well for some time to come that at least one question of this description should be given in every paper.

"ENGLISH.

"This, on the whole, at this examination was the best subject, and very few failed to write the composition creditably. Five candidates failed in English on account of errors in spelling, but the majority had no error of this description. The weakest point was the punctuation, some of the candidates ignoring stops and some others inserting them without any method whatever. I am of opinion that to draw attention to this it would be well that in the next two or three examinations a special test question on punctuation should be introduced.

"In conclusion, I desire to state that the alteration made by the Council in extending the hours of the examination is very satisfactory to the examiner, and, no doubt, it is also to the candidates. Ample time was allowed for carefully answering all the questions, and in very few cases indeed was there any internal evidence of a candidate being hurried."

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	7	2	5	Lancaster	5	2	3
Birmingham	18	9	9	Leeds	14	5	9
Brighton	4	3	1	Lincoln	4	4	0
Bristol	9	6	3	Liverpool	11	4	7
Cambridge	3	1	2	London	32	13	19
Cardiff	6	2	4	Manchester	26	12	14
Carlisle	5	1	4	Newcastle-on-T.	7	4	3
Carmarthen	9	3	6	Northampton	3	1	2
Carnarvon	9	3	6	Norwich	2	1	1
Cheltenham	3	2	1	Nottingham	6	2	4
Darlington	4	1	3	Oxford	2	1	1
Dundee	7	2	5	Peterborough	6	5	1
Edinburgh	19	11	8	Sheffield	5	1	4
Exeter	6	3	3	Shrewsbury	1	0	1
Glasgow	21	9	12	Southampton	5	3	2
Hull	4	2	2	Truro	4	3	1
Inverness	2	1	1	Worcester	4	2	2
Jersey	2	1	1	York	3	2	1

The questions set for examination were as follows:—

LATIN.

(*Time allowed—from* 11 *a.m. to* 12.30 *p.m.*).

I. Translate into English either A. (Cæsar) or B. (Virgil).

The Candidate must not attempt both.

A. Cæsar.

(i.) Tamen, ut spatium *intercedere posset*, dum milites, quos imperaverat, *convenirent*, legatis *respondit*, diem se ad deliberandum sumpturum. (ii.) Ita dies circiter quindecim iter fecerunt, uti inter novissimum hostium agmen et nostrum primum non amplius quinis aut senis milibus passuum interesset. (iii.) His rebus cognitis, Caesar Gallorum animos verbis confirmavit, pollicitusque est, sibi eam rem curae futuram: magnam se habere spem, et beneficio suo et auctoritate adductum Ariovistum finem injuriis facturum. (iv.) Hac oratione habita, mirum in modum conversae sunt omnium mentes, summaque alacritas et cupiditas belli gerendi innata est, princepsque decima legio, per tribunos militum, ei gratias *egit*, quod de se optimum judicium fecisset, seque esse ad bellum gerendum paratissimam confirmavit. Deinde reliquae legiones, per tribunos militum et primorum ordinum centuriones, egerunt, uti Caesari satisfacerent: se neque unquam *dubitâsse*, neque timuisse, neque de summa belli suum judicium, sed imperatoris, esse existimavisse.

B. VIRGIL.

(i) Haec ubi dicta, cavum conversa cuspide montem
Impulit in latus; ac venti, velut agmine facto,
Quà data porta, ruunt, et terras turbine perflant.
Incubuere mari, totumque a sedibus imis
Unà Eurusque Notusque ruunt, creberque procellis
Africus, et vastos volvunt ad litora fluctus.

(ii.) Adloquitur Venus, O qui res hominumque Deûmque
Aeternis regis imperiis et fulmine terres!
Quid meus Aeneas in te committere tantum,
Quid Troës potuere, quibus tot funera passis
Cunctus ob Italiam terrarum clauditur orbis?
Certe hinc Romanos olim volventibus annis,
Hinc fore ductores revocato a sanguine Teucri,
Qui mare, qui terras omni ditione tenerent,
Pollicitus: quae te, genitor, sententia vertit?

II. Translate into Latin:—

(i) It is a mark of a foolish boy to wish to learn nothing. (ii.) What part of our earth is not full of labour? (iii.) Take care that you always follow the path of virtue. (iv.) The signal for battle having been given, the general exhorts the soldiers. (v.) The inhabitants of the provinces have been spared by the merciful conqueror.

III. Answer *four only* of the following questions:—

1. Give the principal parts of the verbs in italics in paragraph A.
2. Give the positive and comparative degrees of all the adjectives in the superlative degree in paragraph A.
3. Decline in full (singular and plural) *his rebus*, *eam rem*, in paragraph A.
4. Explain fully the construction of—*legatis respondit, diem se ad deliberandum sumpturum* (paragraph A, sentence i.), and *magnam se habere spem* (paragraph A, sentence iii.).
5. Give the principal parts of all the verbs in part (i.) of paragraph B.
6. Decline *vires*, *Deûm*, *orbis*, *mare*, in paragraph B.
7. Parse *passis* and *potuere*, in part (ii.) of paragraph B.
8. Make a list of all the deponent verbs in part (ii.) of paragraph B, and give their principal parts.

ARITHMETIC.

(*Time allowed—from* 12.30 *p.m. to* 2 *p.m.*).

1. A barrel containing 40 litres of liquid weighs 40 kilog. 5 hectog.; empty, it weighs 3 kilog. 9 hectog. Give in grams the weight of a litre of the liquid.

2. Simplify $$2\tfrac{1}{2}+\cfrac{1}{3\tfrac{1}{3}+\cfrac{1}{4\tfrac{1}{4}}}-1\tfrac{11}{91}.$$

3. Add together $\frac{3}{8}$ of a guinea, $\frac{3}{13}$ of a crown and $\frac{3}{10}$ of 7*s.* 6*d.*; and reduce the result to the decimal of 16*s.*

4. Divide 76·57 by ·0019; and multiply 50400 by $\frac{3}{7}$ of ·0008568.

5. If a sack of corn containing 1 hectol. 20 lit. cost 18 francs, what ought to be paid (in francs) for a sack of corn containing 1 hectol. 60 lit.?

6. If the rent of 13 acres 1 rd. 14 pls. for 150 days be £125, what quantity of the same quality of land ought to be hired for 88 days for £110?

7. A. can do a piece of work in 3 days, B. can do thrice as much in 8 days, and C. five time times as much in 12 days: in what time would they do it together?

ENGLISH.

(*Time allowed—from* 3 *p.m. to* 4.30 *p.m.*).

1. Name the Parts of Speech, and give, where you can, the derivation of each.
2. Define an Adjective. How are comparatives and superlatives formed in English? When is it impossible for an adjective to have any comparative?
3. State some reasons for considering the English Alphabet to be defective.
4. Correct the following sentences, giving your reasons:—

(*a*) You are a greater loser than me.
(*b*) Who did he give it to?
(*c*) Too great a space separates the third and fourth man.

5. Analyse the following sentence:—

"Kind nature's sweet restorer, balmy sleep,
Swift on his downy pinions flies from woe."

6. Parse the following sentence:—"I can tell you strange news that you yet dreamed not of."
7. Write a short composition on any favourite place or favourite book.

Provincial Transactions.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The thirteenth annual *soirée* in connection with the Midland Counties Chemists' Association was held on Friday evening, January 25, in the Birmingham Town Hall, and from every point of view was the most successful gathering which the Society has held. Early in the evening there was a promenade concert, during which Mr. Stimpson gave an organ recital, and Messrs. Synyer and Gilmer's band performed a selection of music. Later dancing was commenced, and was continued until an early hour on Saturday morning, Mr. E. J. Reynolds carrying out the duties of the M.C. to the satisfaction of the company present. The hall was tastefully decorated by Messrs. Manton and Sons; the plants, of which there was a profusion, coming from Mr. Vertegan's nursery. Everything passed off in a manner highly creditable to Mr. Charles Thompson, who, as Honorary Secretary, had the arrangements of the *soirée* entrusted to his supervision.

LIVERPOOL CHEMISTS' ASSOCIATION.

The seventh general meeting of the thirty-fifth session was held at the Royal Institution, on Thursday evening, January 17, 1884. Mr. Edward Davies, F.C.S., F.I.C., in the chair.

The minutes of the previous meeting were read and confirmed and the following donations to the Library and Museum were announced:—*The Canadian Pharmaceutical Journal*, from the Editor; *The Pharmaceutical Journal* (two numbers), from the Society; and a complete set of the products of the distillation of shale, including specimens of crude shale, from the Young's Oil Co., Addiewell, presented to the Museum by Mr. H. A. Tobias.

The President then called on Mr. Haddock to read the paper of the evening on "The Uses of Permanganate of Potassium in Analysis."

The paper will be printed in an early number of this Journal.

Dr. Symes, in moving a vote of thanks to Mr. Haddock, said he was agreeably surprised to learn that eleven such important substances as those mentioned in the table given could be so successfully estimated by potassium permanganate. He trusted the paper would be published, as he thought it would be a valuable one for reference.

Mr. T. Fell Abraham had pleasure in seconding the vote of thanks, which was supported by Messrs. Parkinson and Ward.

Mr. Davies, in putting the resolution, said that for the estimation of tannin and manganese salts the volumetric method by potassium permanganate was of the utmost value, as the old method was exceedingly doubtful and uncertain, and in the case of manganese, when the quantity of the latter was small, it utterly failed to determine the same.

The motion having been put, was carried by acclamation, and Mr. Haddock having briefly replied, the proceedings terminated.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The Manufacture of Gas from Limed Coal.

On Thursday, January 24, a paper was read by Professor Wanklyn before the Applied Chemistry and Physics Section of the Society of Arts, upon "The Manufacture of Gas from Limed Coal," special reference being made to Cooper's method of mixing lime with coal before distillation. The lecturer commenced by remarking that although the distillation of coal in the process of gas-making forms the chief source of the ammonia of commerce, it is nevertheless a well ascertained fact that only a small fraction of the total nitrogen of coal is made to take the form of ammonia in the distillatory operation as at present carried out. He then proceeded to point out the material differences between the products of the distillation of limed and of unlimed coal, which he said consisted in the limed coal yielding more of its nitrogen in the form of ammonia and a larger fraction of its carbon and a smaller fraction of its sulphur in the form of volatile compounds, besides leaving the coke in a more advantageous state for general use. The quantity of lime allowed in the process referred to, he said, was about half a hundredweight of quicklime to every ton of coal, the lime being slaked with about its own weight of water before mixture. It had been expected that the limed coke would not burn so well as common coke, owing to the presence of a greater amount of fixed matter in the form of lime; but this proved to be an advantage, for the calcium compound, acting as an oxygen carrier, caused the coke to burn more brightly and readily. It was also claimed that whereas common coke, when burnt, gives off fumes of sulphurous acid abundantly, coke prepared from coal properly limed evolves absolutely none. Professor Wanklyn stated that from the 2,000,000 tons of coal carbonized annually by the London gas works ammonia is distilled at an average of from 5 to 6 lbs. of ammonia per ton of coal, but that if the coal were limed before distillation the average would be raised to 12 or 15 lbs. per ton. If all the nitrogen in coal were converted into ammonia the yield would be from 25 to 50 lbs. per ton, but this production would reduce that of coke, as the latter contains a solid carburet of nitrogen. Without laying emphasis on the slight increase in the amount of volatile carbon compounds, the lecturer drew attention to the advantage to be derived from the diminution of the fraction of volatile sulphur when the coal is distilled with lime. He argued that it is known that sulphur present in organic compounds will readily attach itself to calcium if the compound be heated with lime, and therefore, theoretically sulphur cannot be evolved from coal in the presence of an excess of lime. In coal-gas the main portion of the sulphur exists as sulphuretted hydrogen, from 0·8 to 1·5 per cent. by volume being found in crude gas distilled by the common method, and about 0·3 per cent. of "sulphur compounds other than sulphuretted hydrogen." From the results obtained in a series of experiments made with crude gas from limed coal, the lecturer said it had been shown that the volume of sulphuretted hydrogen is diminished by about one-third. Professor Wanklyn further stated that in consequence of the fixation of the sulphur by the lime mixed with the coal, the use of lime purifiers could be dispensed with, whilst those filled with oxide of iron lasted much longer; indeed, it has been practically shown that as low an average as 3 grains of sulphur per 100 cubic feet of gas could easily be maintained by the mixture of lime with coal before distillation, and the use of oxide of iron purifiers alone. As regarded cost, he calculated that from the gain in ammonia and tar and the saving in purifying material, the decrease in expenditure would at least amount to one shilling per ton of coal carbonized. The lecturer concluded his paper by remarking that looked at from the sanitary point of view the use of limed coal would decrease the pollution of the air with sulphurous acid, and render gas as harmless as the electric light.

In the discussion which followed this paper, most of the speakers agreed that there was a considerable increase in the amount of ammonia obtained, which was estimated by some as a gain of about 30 per cent. One speaker stated that he had not noticed any decrease in the amount of sulphur in the crude gas manufactured from limed coal, and that though he had been biassed in favour of the process, he could not call it a success. Another speaker remarked that the white appearance of the limed coke lowered its market value, and the majority condemned its use for the purpose of heating furnaces, because of the damage caused to the flues, which had compelled the process to be stopped. The Chairman, Mr. D. Howard, in closing the discussion, drew attention to the great value now attached to the bye-products of the distillation of coal, as compared with their value a few years ago.

Professor Wanklyn in answer to the statements of some of the speakers, remarked that he thought the failure of the process when tried by them had been owing to imperfect mixture of the lime and coal before distillation. In answer to some questions put forward during the discussion, he stated that the presence of free carbonic dioxide in the gas did not materially diminish its illuminating power, but it had been always removed previously as a preliminary step to the elimination of the sulphur compounds; the oxide of iron purifiers now rendered this step unnecessary. He also reiterated his opinion that no decomposition of the sulphide of calcium took place in the presence of an excess of lime.

Recent Improvements in Photo-Mechanical Printing Methods.

The first of a course of Cantor Lectures, by Thomas Bolas, upon "Recent Improvements in Photo-Mechanical Printing Methods," was delivered before the Society of Arts, on Monday last. The lecturer mentioned that this course would be a continuation of a series of lectures delivered before the Society upon the same subject about four or five years ago. The present lecture was confined to an explanation of the Woodburytype process, the new developments of this method being especially dwelt upon. The process is based upon the fact that gelatine, slightly pigmented with bichromate of potash, is rendered insoluble in warm water by the action of light. Mr.

Bolas, accompanying his remarks by experiments, stated that the old method of obtaining the printing mould was to expose the gelatine with a negative for a certain time to a strong light, and then to wash away the soluble parts from the back or unexposed side with hot water. The mould was then mounted on tin foil coated with copper, and a sheet of glass attached by a resinous composition so as to form a stiff plate which would be able to stand pressure without harm to the mould. A more recent method is to commence by treating the gelatine mould with a solution of indiarubber in benzol; a sheet of tin foil is then placed over it, and in order to insure the tin foil covering the mould closely, they are passed between indiarubber rollers, the pressure being gradually increased. It has been found advantageous to use steel-faced tin foil for this purpose, the facing of steel enabling the mould to keep its surface for a longer time. Among some curiosities that the lecturer showed was the first printing mould made by Mr. Woodbury, and also some of his earliest printings. During the lecture, Mr. Bolas mentioned that it is little known that when ordinary paper is submitted to a high pressure it becomes semi-transparent, like opal glass or ordinary porcelain. Advantage has been taken of this by French manufacturers to copy watermarks, and some ingenious imitations were passed round for inspection. In concluding, he remarked that so rapid had been the improvements in photo-mechanical printing, that he considered it reasonable to expect that in a few years' time we might see photographs printed in the newspapers.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, January 24, Mr. H. G. Greenish, Vice-President, in the chair.

The first paper read was the following—

Note on Iodide of Cadmium.

BY F. W. SHORT.

Of late years, a good deal of speculation has taken place with regard to the elements, as to whether the bodies now generally considered elementary, because we have not yet been able to further decompose them, are actually *bonâ fide* elements, or whether many of them are not in reality compound bodies, like ammonium, but of very great stability. The relation between the atomic weights of many elements which display great similarity in other respects, such as chlorine, bromine and iodine, for example, has been thought to point to the conclusion that these bodies may really be compounds of actual elements in different proportions, similar to the hydrocarbons and analogous groups in the organic kingdom. For just as in the hydrocarbons, etc., we get a constant increase in molecular weight and an increased melting or boiling point for every CH_2 group introduced into the molecule, so in this series of elements, for example, as we ascend from the lowest or gaseous chlorine, to the liquid bromine and solid iodine, we get an increase in atomic or molecular weight corresponding to the increased boiling point.

If this speculation were correct, we should expect to find among the elements of higher atomic weight more examples of isomeric compounds than among the lower, just as is the case with analogous groups of organic bodies; and this is certainly the case with iodine, the yellow and red iodides of mercury and the three iodides of antimony being examples.

In order to ascertain if any other iodides presented similar modifications, Messrs. F. W. Clarke and E. A. Kebler have lately made various experiments, chiefly with iodide of cadmium, and their results were published in the *Chemical News* for December 28, 1883. They state that they prepared iodide of cadmium in various ways and obtained it in two distinct forms, one having a specific gravity of about 4·6, and the other, which was the commoner and more stable modification, about 5·6. Specimens prepared by digesting cadmium and iodine in sealed tubes exhausted of air and crystallization from water, by digesting the elements in water, and by double decomposition with cadmium sulphate and potassium iodide, all gave a specific gravity between 5·5 and 5·7, while a specimen prepared by dissolving cadmium carbonate in hydriodic acid and taking up some free iodine which had been produced with a little metallic cadmium, showed a specific gravity of 4·6; this was proved by quantitative analysis to be practically pure CdI_2. Three more specimens obtained by dissolving the carbonate in hydriodic acid all had the higher specific gravity. Another specimen of low specific gravity, viz. 4·638, was obtained by dissolving metallic cadmium in hydriodic acid; this was found to lose weight considerably on heating, becoming partially insoluble; by merely heating to 50° C. its specific gravity was altered to 5·14, and on twice more heating to 50° C. it rose to 5·545, showing according to the authors that the salt of lower gravity was very unstable and converted by heat into the other variety. They cannot state the conditions under which this unstable modification is formed, but suggest that nascent hydrogen may have something to do with its production, as in each case where they obtained it the salt had been exposed to nascent hydrogen.

I have made a few experiments in order to try and obtain a specimen of each kind to place before you. In the first place I took the specific gravity of three commercial specimens, using benzene, the medium employed by Messrs. Clarke and Kebler, with the following results:—

A	specific gravity 5·455
B	specific gravity 5·485
C	specific gravity 5·584

These salts were all taken in small crystals, and, evidently, all consisted of the normal variety. A specimen of cadmium iodide was then prepared by digesting together cadmium and iodine in water at about 60° C. until colourless, evaporating over a water-bath and crystallizing. The crystals were dried over sulphuric acid without heat, and were quite pure; their specific gravity was 5·667.

A specimen prepared by dissolving cadmium carbonate in hydriodic acid, adding a little metallic cadmium to combine with free iodine (the method by which Messrs. Clarke and Kebler obtained one of their abnormal specimens), evaporating to crystallization over a water-bath and drying over sulphuric acid, had a gravity of 5·089.

Another specimen was prepared by mixing equivalent proportions of sulphate of cadmium and iodide of potassium, evaporating to dryness over a water-bath, extracting the cadmium iodide with alcohol and allowing it to crystallize. The specific gravity of this was taken in small crystals, as in the preceding cases, but in this case more difficulty was experienced in getting rid of all air-bubbles. After considerable agitation, when no more bubbles seemed to come off, the specific gravity was, apparently, 4·511; however, on standing twenty-four hours, more bubbles could be got off, raising the apparent specific gravity to 5·347.

One of the other specimens (sp. gr. 5·667) was dissolved in alcohol and subjected to the action of nascent hydrogen obtained from metallic sodium. The soda was neutralized by sulphuric acid, and the alcoholic solution of cadmium iodide filtered off and crystallized. The specific gravity was taken in crystals, and the same difficulty was experienced with regard to air-bubbles as in the preceding case, where the salt had also been crystallized from alcohol. A first determination gave only 4·152, but after standing five or six hours, more air could be got off, and it then seemed 4·287. It appeared more probable, therefore, that the apparent lowness of specific gravity was due rather to air being inclosed in the interstices of the crystals than to the salt being abnormal, so a portion was rubbed into a fine powder and its specific gravity determined in that condition, when it was found to be 5·778.

As the salt when crystallized from aqueous solutions did not present the same difference between the crystals and the powder, it was thought that this might be due merely to their crystallization from alcohol; one of the preceding specimens (specific gravity 5·485) was therefore dissolved in alcohol and crystallized out.

The crystals were placed with benzene in a specific gravity bottle and placed under the bell-glass of an air-pump until no more air-bubbles could be got off; the gravity was then taken and found to be 4·375. More of the crystals on being powdered gave a specific gravity corresponding nearly with that originally found.

These results show that iodide of cadmium obtained by crystallization from alcohol has generally a lower specific gravity than that crystallized from water, but that this is probably due to the presence of air in the crystals, and not to their being in the abnormal condition described by Messrs. Clarke and Kebler, who do not state whether they used crystals or powder for the determination of the specific gravity. I have been unable to obtain any specimen which when powdered had a gravity less than about 5·5.

A discussion followed in which the Chairman, Secretary, Messrs. Dymond, Elliott and Thompson took part.

A vote of thanks was passed to Mr. Short.

The Reporter on Analytical Chemistry, Mr. C. Thompson, then read a report on "The Qualitative and Quantitative Separation of Chlorides, Bromides and Iodides," in which he brought under notice a modification of Vortmann's method, proposed by F. Jones, for their qualitative separation, and also the method proposed by Julius for their quantitative determination, based on replacing the halogen elements in the silver salts by each other. Mr. Thompson said he was still experimenting with these processes and would bring forward his results at a future meeting.

A discussion followed the report in which the Chairman, Secretary, Messrs. Cullinan, Dymond, Elliott, Ranken and Short took part.

The meeting then adjourned.

Parliamentary and Law Proceedings.

Poisoning by Prussic Acid.

An inquest was held in Worcester by Mr. R. T. Rea, City Coroner, on Thursday, January 24, concerning the death of Eliza Ross, aged 40, and her child, aged 6. It appeared that the deceased had been living apart from her husband and had been much depressed in consequence of not being allowed to have access to her children. On the day of her death she appears to have fetched the deceased child from school and the two were afterwards found dead together.

William Morris, chemist, Lowesmoor, said: On Monday evening last about seven o'clock I sold six pennyworth of prussic acid to the deceased. I knew her. The quantity was 3 drachms, which would be about three teaspoonfuls. Fifteen drops is a fatal dose, and the quantity I sold to deceased would make ten such doses. I observed the usual requirements of the law in selling the poison, and received from deceased the name of "Mrs. Jones, Carden Street." She paid the sixpence for it, and took the bottle produced away with her.

The Coroner: You said you knew deceased. Did you know her as Mrs. Jones?

Witness: I did not know her by name. I knew her as a customer for twelve months past. I had had no occasion previously to ask her name.

The Coroner: Was there anything particular about the manner of deceased to excite suspicion?

Witness: Nothing at all.

The Coroner: Did she appear calm, collected, and reasonable?

Witness: Yes.

The Coroner: Was anything said when you sold her the poison?

Witness: I asked her if she knew prussic acid was a powerful poison. She said "No." I asked her what she wanted it for. She said a friend had told her it was an excellent thing to clean with. I suggested that she should use some salts of lemon instead. She said, "I have tried that, and it has not answered." I produced my book, and said she would have to sign her name and address. Deceased said, "I have no objection to sign; I have done the same in purchasing mice poison at other shops." Whilst she was signing the book, which she did very slowly, I ran over the probabilities of the case, and as deceased had before bought laudanum of me, and had made no improper use of it to my knowledge, I considered it a *bonâ fide* purchase, and I let her have the prussic acid. Deceased received it in the bottle in which she had previously purchased laudanum.

Witness produced his register of the sale of poisons, and showed that the sale in question was attested by the name and address of the purchaser, the quantity and nature of the poison sold, and the purpose for which it was bought. There was, however, no signature in the space provided for the person introducing the purchaser, and Mr. Power, who was present throughout the inquiry, pointed out that the sale was therefore not in accordance with the statute.

Mr. Morris said he did not consider any introduction necessary in this caee, as deceased was an old customer.

Dr. Crowe said on Tuesday evening he was fetched to Mrs. Deakin's, in Lowesmoor, and saw the body of the deceased there, in a water closet. He had since made a *post-mortem* examination of the body. He discovered the presence of prussic acid by a chemical test.

Mr. Power (to witness): Have you ever heard of prussic acid being used for cleaning dresses?

Witness: Never.

Mr. Power: Is it usual for chemists to sell prussic acid for that purpose?

Witness: I think not.

Mr. Power: Do you think if I were to go to Mr. Virgo's or Mr. Steward's they would sell me prussic acid?

Witness: I should think they would not give it you in a poisonous quantity unless prescribed by a medical man. A fatal dose of Scheele's acid is twenty drops; and that is two and a half times stronger than the prussic acid usually sold.

After hearing other evidence, the Jury found a verdict "That the deceased committed suicide whilst in a state of temporary insanity, and also that she destroyed her child in a fit of temporary insanity." They added a rider to the effect that greater restrictions should be placed upon the sale of poisons.—*Worcester Daily Times.*

The "Indian Tincture" Poisoning Case.

The adjourned inquest on the body of Samuel Yates, nine years of age, son of John Yates, collier, Moss Bank, near St. Helens, was held on Saturday last by Mr. Hardy, Deputy Coroner. Mr. Finney, solicitor, Bolton, appeared to represent the maker of the Indian tincture, Mr. William Riley, licensed patent medicine dealer, Daubhill, near Bolton; and Inspector Whitaker watched the proceedings for the chief constable of the county. The facts, as already published, are that on the morning of the 12th inst. deceased complained of being sick and purged, and about noon his mother went to the shop of William Ashall, grocer, Moss Bank, and purchased an ounce of "Indian tincture," for which she paid 3*d.* On her return home she put a teaspoonful of warm water to the tincture and gave it to the sick boy. She then put him to bed, and left his step-brother, a lad named Cartwright, in the house, while she went to St. Helens. When his mother came home he was in a comatose condition, and died a quarter of an hour afterwards.

At the inquiry on Saturday the mother of deceased repeated her evidence, and said she had never before given

Indian tincture to any of her family. Some fifteen months ago her step-daughter, a young woman of twenty-five years, while in her house had bowel complaint, and she took ninepennyworth (three onnces) in five days. In cross-examination by Mr. Finney witness said it did her daughter-in-law good. She drank threepennyworth at a time.

The Coroner: But you know, Mr. Finney, her daughter-in-law is twenty-five years of age.

Witness: Ah! that makes the difference.

William Ashall said he sold the tincture to Mrs. Yates. He purchased it about five months since from William Riley, Daubhill, near Bolton. He had sold the tincture for five or six years. Working people—generally women—purchased it. From the time he received the tincture to the time he sold some of it to Mrs. Yates he did not put anything in it—he sold it in exactly the same state as it was in when he received it. He could not say that he ever knew an adult take an ounce for a dose. He had taken it himself, and drunk it out of the bottle many a time, not thinking it was anything dangerous.

The Coroner: Now you won't drink any more?

Witness: No fear.

The Coroner: What was the sensation after you had taken it—soothing, lulling?

Witness: When I have felt cold I have tasted it, and felt no different.

The Coroner: What age are you?

Witness: Thirty-three.

The Coroner: There is a difference between eight and thirty-three.

In reply to Mr. Finney, witness said he had sold it for children out of the particular bottle. About four weeks since he had sold half an ounce to Mrs. Yates for a child who was a little younger than deceased. Mrs. Yates told him herself it was for her child. She asked him if half an ounce would be too much for a child, and he (witness) replied that he did not know, but thought not. He then read her the doses from the label. He could not just say whether he had sold it to other people for children. They did not always say who it was for. Witness did not give Mrs. Yates instructions on the last occasion.

By the Coroner.—He was quite certain that Mrs. Yates came and purchased half an ounce of tincture from him four or five weeks ago.

Mr. Finney remarked that Mrs. Yates stated in evidence she had not had any before.

This was the whole of the evidence.

The Coroner said he had received Dr. Campbell Brown's report of his analysis, which he read, as follows:—"Analysis of a bottle labelled 'Indian tincture,' received from Mr. Superintendent Johnston, proves it to contain about 30 per cent. of its volume of methylated spirit, a small quantity of ether, and a very large proportion of sugar, probably more than 30 per cent. of its weight. It also contains two resins, one derived apparently from capsicum or cayenne pepper, and the other present in only very small quantities, and accompanied by other vegetable extractive matter. The weight of the two resins taken together is only 0·012 per cent. The smaller quantity of resin is not capable of being identified by any chemical means, and I believe that the only way in which its properties might perhaps be determined would be by making experiments on living animals. This I am prohibited by law from doing, and I can only conjecture that the resin may possibly be derived from Cannabis Indica or Indian hemp, a substance which yields such a resin, and which produces symptoms similar to those which have been described to me as resulting from the use of this tincture. At the same time I should point out that the administration of methylated spirit and ether was a dangerous proceeding, and might have produced many of the symptoms observed in the present instance. The tincture contains no opium. I have analysed the stomach and contents, and further examined the bottle of intestines. I have extracted from the stomach a small quantity of alcohol, and a trace of some resinous substance which it is quite impossible to identify. No opium is present, and there is no trace of any ordinary poison."

The Coroner then proceeded to address the jury. Having carefully reviewed the evidence, Mr. Hardy said the jury would have no difficulty in coming to the conclusion that the boy's death resulted directly from his mother having administered this Indian tincture. Was anyone responsible to the law for his death? He thought there was not the slightest evidence upon which they could answer that Mrs. Yates's object was any other than to see him better—a desire to stop his vomiting and purging. There was no suspicion, and the police did not even suggest any idea of foul play. That being so, he must tell the jury, and they must take the law from him, that what the mother did was in ignorance. Ashall was the next man who had to do with the Indian tincture. He would not say this man was guilty of gross neglect, but he did not evince that care and caution which a man with his intelligence should have done. He (the Coroner) had seriously considered whether he should not direct the jury to place him upon his trial for a serious charge, but having found from the police that he had evinced a great desire to assist them in this inquiry, and having heard his straightforward evidence, he did not think he had been guilty of wilful neglect, gross carelessness and recklessness, which the law required them to find before they called upon him to answer a charge of manslaughter. Then they came to the third person, Mr. Riley, by whom this mixture was made and sold to small shopkeepers. This Indian tincture evidently included injurious and deleterious ingredients, and was sold for all complaints, its virtues and efficacy being set forth in highly flown language on the labels. Although he might tell them that Mr. Riley was not criminally liable, he might be responsible to the law in another way which did not concern the jury. Especially he would direct the attention of the Inland Revenue authorities to the report which he had read from Dr. Campbell Brown and to the law relating to pharmacy. It was a most unfortunate state of things that men like Mr. Riley, in Liverpool, Manchester, Preston, and elsewhere should be permitted for one moment to concoct these mixtures and go about to little shopkeepers, or that the little shopkeepers should be permitted to retail such deleterious and injurious medicines. He had been told since that inquiry commenced by several medical gentlemen who had seen him and written to him, that if the public only knew the number of infants' lives that were annually sacrificed through their mothers dosing them with syrups and other compounds, they would be positively astounded. He (Mr. Hardy) had frequently held inquests upon children, and he was beginning to think himself, that in many cases where verdicts were returned, "Found dead in bed," "Died from convulsions," and so on, if they could get at the truth, it would be found that death was really the result of dosing them with syrups and other like compounds. Medical gentlemen had told him that the system of preparing and retailing these tinctures and drugs was doing a great harm to the working classes, and that even women were going to shops and drinking it as they would other things. Superintendent Johnston, of St. Helens, had taken the trouble to ascertain how many shopkeepers in St. Helens alone sold these mixtures containing opium and methylated spirit.

Mr. Finney: You do not mean shopkeepers who sell Indian tincture?

The Coroner said he meant Indian tincture and kindred mixtures. There were ninety-three shopkeepers in St. Helens who sold these mixtures. He believed they were all of a like kind to Indian tincture. He did not know whether they all contained such ingredients as Indian hemp, which was a powerful sedative, but some of them he believed did contain opium. In the Rainford section, of which Police-sergeant Smith had charge, there were eleven shops; and Superintendent Weir, of Wigan, said that within a mile radius of the spot where he was located there were some thirty or forty persons who were selling not only Indian tincture, but kindred mixtures. In his (the Coroner's) opinion shopkeepers ought to be prohibited from dealing in these compounds. In this case he could not acquit Ashall from all blame; as it was his duty to have read over the label. The jury might say, if they liked, that the law ought to absolutely prohibit shopkeepers from selling these injurious and deleterious compounds.

After an absence of twenty minutes, the Jury returned with the following verdict:—"That the boy Samuel Yates died from the effects of the overdose of a mixture called Indian tincture, which was administered to him as medicine by his mother by misadventure." They also desired to say that although William Ashall was not criminally responsible for the death of deceased, they thought he deserved some censure for not informing the mother of deceased when she bought the mixture that the dose was as it appeared upon the label of the bottle produced, which he kept in the shop, and that Mrs. Yates was also to blame for not inquiring what should be given to a child. They further desired to make a presentment that they thought all shopkeepers ought to be absolutely prohibited by law from selling Indian tincture and mixture of a similar kind; and if in this case the law relating to the Inland Revenue had been broken by the manufacturer of this Indian tincture they hoped steps would be at once taken by the proper authority to enforce the penalty fixed by law. Mrs. Yates and Mr. Ashall were then called into the room and censured by the Coroner.—*Liverpool Daily Post.*

Poisoning by Ammonia.—A Wrong Bottle.

On Friday, January 25, a man named George Wragg died at Sheffield from poison administered to him by his mother, under the belief that it was a dose of medicine. The deceased was in well-to-do circumstances. He was married, but he separated from his wife some time ago, and had since been living with his mother. He had been under medical treatment for indigestion, and had been taking medicine. After he retired to rest on Thursday night his mother, an old lady of eighty, gave him what she thought was a dose of the medicine. The bottle, however, contained strong ammonia, which Wragg purchased some time before to clean some clothes. He soon afterwards experienced all the symptoms of having taken an irritant poison, and, in spite of prompt medical attendance, died in three hours.—*Standard.*

Poisoning by Arsenic.

On Monday, Mr. Hull resumed an adjourned inquest at Wandsworth Prison, on the body of George Robinson, aged 51, lately dwelling in Walworth, who died as reported last week.

Barnett, coroner's officer, stated that he had searched Mr. Robinson's room. Witness found a number of bottles, one of which contained arsenic. The deceased was traveller to a chemist.

The widow of the deceased, after having been cautioned by the Coroner, said that for years past her husband had been given to drink. He had struck her with a sharp instrument. While he was waiting at the police court she gave him a meat sandwich and some ale. After he had been sentenced he said to witness, "I shall never go through this three months," and asked for some more refreshment. She procured him some coffee, which he partook of.

J. Clarke, a friend of the deceased, stated that he accompanied last witness to see her husband. He procured some coffee from a neighbouring coffee house, and handed it to the gaoler, who gave it to the deceased.

The Coroner remarked that he was not satisfied with the evidence. He should report the case to the Home Secretary, and ask him to take up the matter.

After hearing the evidence of the daughter of the deceased, the case was again adjourned.—*Standard.*

The Solubility of Calcic Hydrate.

Sir,—I am pleased that Mr. Abraham has called attention to my statement regarding the solubility of calcic hydrate in the presence of carbonate, as I am unwilling that an error on my part should go forth uncorrected.

In estimating the proportion of hydrate in solution when carbonate was present, I did not allow the mixture to stand longer than two hours, and to this cause my low results are no doubt due. Believing, however, that I had not been so very far from the mark as Mr. Abraham's communication would show, I repeated his experiments, taking the precaution to wash the mixtures of hydrate and carbonate previous to use. After twenty-four hours the solutions were filtered, and titrated with seminormal oxalic acid, the following results being obtained:—

Percentage of $CaCO_3$ present.	Grain measures, seminormal oxalic acid required to neutralize 1000 grains.	Equal to grains CaO per fluid ounce.
15	90	·55
50	89	·54
75	87	·53
90	60	·36

From this it is evident that the admixture of carbonate with hydrate does make a difference in the strength of the solution, though the variation is not so great as my former statement indicated. The titrations were repeated in presence of my analytical assistant, Mr. Dechan, with the normal oxalic acid in use in the laboratory, the results obtained being practically identical with the above.

Without going into all the points raised in Mr. Abraham's letter, I may direct attention to his table, which bears internal evidence of untrustworthiness. I refer to the facts that all the four solutions contained lime in suspension; that No. 2 held more in suspension than No. 1 (and we might quite reasonably infer that Nos. 3 and 4 held more than No. 2), and that Nos. 3 and 4 are relied upon to prove Mr. Abraham's position, though it is evident that, the solutions not having been filtered, the results cannot be accepted as correct.

With reference to the solubility of the pure hydrate, it is apparently almost hopeless to expect any two observers to agree. It was not till after I had quite finished all my observations and was looking up the results obtained by others, that I began to realize how difficult it would be to arrive at figures that would be accepted as correct. There are contingencies connected with the test solutions in which the slightest variation of strength would show a considerable difference in the results, and sources of variation even in connection with the indicators employed, as shown by Mr. Thomson, in a recent number of the *Chemical News*, which render it highly probable that different results would be obtained by different observers. Any value that my paper may possess lies not so much in the fact that lime is stated to have a given solubility—the correctness of which might readily be disputed—but in the influence shown to be exerted by different temperatures, an influence which is well enough known, but which had not hitherto, so far as I am aware, been systematically investigated.

Hawick. Thos. Maben.

The Examination of Chemicals.

Sir,—Will you allow me to remark upon a few points in Mr. Symons's contribution to your issue of the 19th instant? The value of such examinations is beyond question, but I fear that it is only too often left undone.

Liquor Potassæ.—Twenty ounces of pot. bicarb. would require 14·8 ozs. of slaked lime to combine with the whole of the carbonic acid thus—

$$\underset{100}{KHCO_3} + \underset{74}{CaHO_2} = KHO + H_2O + CaCO_3$$

It would appear as if Mr. Symons calculated pot. bicarb. as containing two molecules of water, but the test of purity given in Squire's 'Companion,' namely, 50 grains heated to redness leaves $34\frac{1}{2}$ grains, *i.e.*—

$$2\,KHCO_3 = K_2CO_3 + H_2O + CO_2$$
$$\frac{200}{4} = 50 \quad \frac{138}{4} = 34{\cdot}4$$

negatives this idea.

Peroxide of Hydrogen.—This unstable compound deteriorates rapidly, and therefore approximation to the stated strength is the best that we can expect to get. Mr. Symons's samples would seem to be rather bad, the volume strengths being properly only half of what he states, for half of the oxygen liberated is due to the bichromate. (See a paper in the *Analyst* for this month.)

Citrate of Magnesia.—It would be interesting to know what the public expect to receive when they ask for this; generally, I think, a powder which effervesces when dissolved in water, therefore the above is an obvious misnomer, for even a mixture of carbonate of magnesia and citric acid is not citrate of magnesia until chemical combination has actually taken place. I may presume (from experience) that the composition of the remainder of Mr. Symons's sample, which he omits to give, was sodæ bicarb. and ac. tart., or perhaps the latter partly replaced by ac. citric.

Liq. Sodæ Effervescens.—It is a well-known fact that only a few of the so-called soda waters contain any added soda at all, and it is well for the general consumer that they do not. I make this remark principally in order to advocate the alteration of the title of the beverage to aerated (or carbonated) water; also the manufacture of medicinal waters of various strengths, say 5 grains, 10 grains and 15 grains per bottle. The statement that ordinary town water contains chalk equal to 1·5 grain of sodic carbonate in each half pint is quoting from very widely differing quantities. I have before me the results of a great number of analyses of water supplies, and see that the temporary hardnes (due to $CaCO_3+MgCO_3$) calculated as Na_2CO_3, varies from ·1 to 1·5 grain per half pint.

W. O. Nicholson.

The Supply of Prussic Acid.

Sir,—I should think most chemists who have read the Newton Abbot poisoning case, reported in the Journal of January 19, will be rather staggered to learn that anybody unconnected with the medical profession (either known or unknown to the seller) should have got possession of 6 drachms of prussic acid.

"Favourite dogs" on this side of the border are usually disposed of by the administration of prussic acid at the hands of the chemists' apprentices, who are careful enough with the dangerous drug. Signing the poisons sale book will not prevent suicide.

N. B.

In re Patent Medicines.

Sir,—In the Journal of January 12, Dr. Connell expresses his surprise that so many who are makers of patent medicines are unconnected either with pharmacy or medicine, and calls upon pharmacists to combine with medical men in order that the supply of medicines should be distributed through the proper channels; whilst, on the other hand, Mr. Allen says dispensing chemists would be only too willing to assist in the matter. Dr. Connell seems to be unaware of the fact that the chemist and druggist assists and greatly encourages the sale of patent medicines. Not only do the greater body of them conspicuously display the show cards, distribute the hand bills, and disseminate the other literature of the patent medicine vendors, but if we are to believe some of the advertisements, many of the trade, so anxious are they to oblige the maker and also benefit (?) the public that they write testimonials and otherwise manifest great anxiety to forward the sale, frequently also personally recommending the articles, to the amusement doubtless, and certainly to the profit, of their sometimes next-door neighbour, the oilman, etc., who, when a demand has been created by his shortsighted fellow-tradesman, lowers the price and sells the medicine. But Dr. Connell would be more astonished did he know that some of his medical brethren not only refrain from discountenancing the use of patent medicines put up by anybody, but also recommend and thus encourage the sale of them. Thus, it appears to me, those doctors and pharmacists both proclaim to their respective patients or customers, either that they are not capable of ministering to the needs of the public, or that they are indifferent alike to their own interests and also to those of other members of their own profession. The public must perceive this, and respect them accordingly.

Is Mr. Allen unconscious of these facts? We must have respect for ourselves before we ask others to respect us.

Pondo.

Sir,—With your kind permission I should like to say a few words on the important question of patent medicines. I am inclined to think it would be much better for the trade at large, it would improve our position in the estimation of an intelligent public and the medical profession, if chemists as a body, instead of puffing and supporting by every means in their power every nostrum that springs into publicity, would do all they possibly could to discourage the sale of them, and on the other hand, recommend to their customers, requiring medicine for slight indisposition, some preparation of their own with which they are thoroughly acquainted, and in which they have every confidence. I think it beneath the dignity of a chemist, with his knowledge of drugs and after the training he has had to go through, to recommend patents of which he, as a rule, knows absolutely nothing, and which generally are compounded of drugs and chemicals of a dangerous character.

Dispenser.

M. Conroy.—Thanks for your communication.

Alpha.—(1) The dispenser would not be justified in substituting one article for another, though he might on occasion withhold a dangerous dose; but 15 grams of potassium iodide is not a dangerous dose. (2) See a note on the change of colour this ointment is subject to in "Dispensing Mem.," No. 130, *Pharm. Journ.*, [3], ix., 65.

W. P.—Thanks for your note. You will see that the "Month" has not been omitted, but postponed, as is our practice occasionally when the last Saturday in the month falls early. We are glad to know that you so much appreciate this article.

Student.—A satisfactory mixture appears to be unobtainable. The prescriber should be referred to.

Inquirer.—Rub the quinine, finely powdered, with a little mucilage, and dissolve the salicin in a little of the aq. chloroformi with the aid of heat. A mixture containing tinct. sumbul and tinct. nucis vom. cannot be otherwise than opaque.

W. Barron.—The U.S.P. tinct. gelsemii is made by percolation with alcohol, specific gravity ·820, 15 parts of finely powdered rhizome being used for 100 parts of finished product.

H. Rainsford.—We are unacquainted with the book mentioned.

T. G. R.—The language of the 30th section of the Dentists Act is that "every person registered under this Act, shall be exempt, if he so desires, from serving on all juries and inquests whatsoever."

Annikcam.—The statement as to the solubility appears as quoted in the earlier editions of the work. We have forwarded your letter to the writer of the paper.

Hibernia.—The Pharmacy Act, 1868, does not extend to Ireland; but pharmacy in that country is regulated by an Act passed in 1875.

Novice.—We shall be happy to name the specimens if they are in good condition and do not exceed six in number.

Communications, Letters, etc., have been received from Messrs. Samuel, Ince, Gatehouse, Kerr, Masters, MacEwan.

REPORT UPON THE PHARMACEUTICAL PREPARATIONS OF NUX VOMICA.*

(*Continued.*)

IV. THE PREPARATION OF A STANDARD EXTRACT OF NUX VOMICA.

BY WYNDHAM R. DUNSTAN,

Assistant Lecturer in Chemistry and Physics to the Pharmaceutical Society and Demonstrator of Practical Chemistry in the School of Pharmacy;

AND F. W. SHORT,

Assistant Demonstrator of Practical Chemistry in the School of Pharmacy.

In previous communications to this Society and to the British Pharmaceutical Conference we have described the results of a chemical investigation of *Strychnos Nux-vomica* and its pharmaceutical preparations. Processes for the estimation of the total alkaloid in the nux vomica seeds, in the tincture and in the extract have been devised, and a method for the quantitative separation of strychnine and brucine has been proposed. At the last meeting of this Society the results of some experiments were communicated relative to the extractive power of alcohol of various degrees of dilution for the alkaloidal salts which are contained in nux vomica. Now our analyses of authentic and commercial specimens of nux vomica have shown that different specimens vary very considerably in alkaloidal content, and a very serious want of alkaloidal uniformity has been shown to obtain in the instance of commercial tinctures and extracts of nux vomica. In the present papers it is intended to apply the results of the above investigation in the preparation of a standard extract and tincture of nux vomica, that is, an extract and tincture of nux vomica which shall contain a definite and constant quantity of total alkaloid. Perhaps the most obvious method of attaining such a result would be in the first place to obtain a specimen of nux vomica which contained a known percentage of total alkaloid, and completely to exhaust a certain weight with a definite volume of alcohol. There are, however, certain practical difficulties connected with the complete exhaustion of nux vomica by a definite volume of spirit, and still greater difficulties in obtaining nux vomica constant in percentage of alkaloid, that led us to work upon somewhat different lines.

It is proposed at the outset to take a good commercial specimen of nux vomica in powder. We have previously shown that the powdered nux vomica at present in commerce is free from adulteration, and hence this substance can be used with advantage for the present purpose. In case of a necessity arising for obtaining nux vomica seeds in fine powder it should be noted that we have in a previous paper given a method for easily effecting this (*Pharm. Journ.*, [3], xiii., 1053). Commercial specimens of nux vomica contain, on an average, 3 per cent. of total alkaloid. The seeds having been obtained in a fine state of division they are extracted by percolation with a definite volume of alcohol of specified strength. The percolate is then measured and the quantity of total alkaloid is estimated in a given volume of it. The volume of this percolate which contains a quantity of alkaloid corresponding to the percentage of alkaloid which should be present in the extract is then taken and evaporated to a definite weight. We have fixed 15 per cent. as the quantity of total alkaloid which shall be contained in the standard extract of nux vomica; this decision is based upon a careful consideration of the results of our analyses of the extracts of nux vomica which are now used in medicine, which results were communicated at the last meeting of this Society.

It will be necessary now to consider some important practical questions connected with the actual preparation of the extract. It cannot, in the first instance, be too strongly insisted that the seeds should be in a very fine and uniform state of division, for unless this is the case, thorough and uniform extraction is impossible. In the extraction of the seeds we recommend the employment of a dilute alcohol, made by adding 25 volumes of water to 100 volumes of rectified spirit, for we have previously shown that alcohol of this strength has the highest solvent power for the alkaloidal salts which are contained in nux vomica. Extract of nux vomica is usually made by boiling the nux vomica with alcohol until exhausted; but it seemed to us that if the nux vomica could be exhausted with a comparatively small quantity of spirit without the aid of heat there would be a distinct advantage, especially in the manufacture upon the small scale. Experiments were therefore made in this direction. Thirty grams of nux vomica in impalpable powder were packed in a stoppered percolator, mixed with 60 cubic centimetres of alcohol (100 : 25) and allowed to macerate for twelve hours. Percolation was then commenced and when it had ceased an additional 60 cubic centimetres of the alcohol were poured upon the marc. When this had ceased to pass through the percolate measured 80 cubic centimetres. Sixteen cubic centimetres were analysed by the process which has been previously described (*Pharm. Journ.*, [3], xiv., 441), and it was found that the 80 cubic centimetres of alcohol had extracted 0·735 gram of alkaloid. A portion of the specimen of nux vomica employed had been previously assayed and found to contain 2·66 per cent. of total alkaloid; 30 grams consequently contained 0·8 gram of total alkaloid, so that 92 per cent. of the total alkaloid had been extracted by the 80 cubic centimetres of alcohol. To the marc were now added another 60 cubic centimetres of the alcohol; the percolate was analysed and found to contain 0·041 of alkaloid, making a total of 0·775 gram of total alkaloid extracted from 30 grams of nux vomica, which contained 0·8 gram of total alkaloid.

These experiments were now repeated upon a larger scale, and the quantity of extract as well as of total alkaloid was estimated in each successive fraction of the percolate. One pound of finely powdered nux vomica was intimately mixed with one pint of alcohol (100 : 25) and allowed to macerate for twelve hours. Percolation was then commenced and continued with more alcohol, portions of the successive fractions of the percolate being assayed for total alkaloid. A total quantity of four pints of alcohol was employed. The results were as follows:—

One pound of nux vomica, containing 189 grains of total alkaloid, was extracted with 4 pints of dilute alcohol (100 : 25).

* Read at an Evening Meeting of the Pharmaceutical Society, February 6, 1884.

Fractions of percolate.	Volume of fraction.	Amount of extract containing 22·67 per cent. of moisture.	Amount of total alkaloid (strychnine and brucine).
First fraction . .	26 ounces	856 grains	125 grains
Second fraction .	16 ounces	220 grains	32 grains
Third fraction .	10 ounces	74 grains	11 grains
Fourth fraction .	10 ounces	29 grains	3 grains
Total percolate .	62 ounces	1179 grains	171 grains

These results show that, proceeding in the above way, nux vomica is practically exhausted by four times its weight of alcohol of the specified strength. It will be noticed that maceration and percolation were adopted, principally because it was found that the first fraction of the tincture made by direct percolation deposited, after a short time, a flocculent precipitate that was not permanently redissolved by heat. No such result occurred when maceration was adopted, although the strong tincture if kept for some time, especially in cold weather, deposits a substance which is apparently a fatty acid and consequently contains no strychnine or brucine, and by gently heating is permanently redissolved. It now remained to prepare the extract from this strong tincture in which the amount of alkaloid was known. After a number of preliminary experiments it was found that 9 ounces (fluid) of this strong tincture, containing 10 grains of total alkaloid, were converted into an extract of suitable consistence by evaporating upon the water-bath until the product weighed 66·6 grains; that is, contained 15 per cent. of total alkaloid. In order to confirm the calculated alkaloidal content of this extract 1 gram was assayed and yielded 0·151 gram of total alkaloid, thus agreeing admirably with the calculated percentage (15 per cent.). We then prepared this standard extract from different specimens of nux vomica, representing high and low percentages of total alkaloid, and found that in all cases it was feasible to prepare a product having all the physical properties of a good extract and containing 15 per cent. of total alkaloid by the direct evaporation of the strong tincture.* The following is a description in official phraseology of the process which we propose for the preparation of a standard extract of nux vomica.

Take of—

Nux vomica in fine powder . .	1 pound.
Rectified spirit	64 fluid ounces.
Distilled water	16 fluid ounces.

Mix the spirit with the water and make the nux vomica into a paste with one pint of the mixture. Allow this to macerate for twelve hours, then transfer to a percolator and add another pint of the mixture. When this has percolated, pour on the remainder of the diluted spirit in successive portions; press the marc, filter the expressed liquid and add it to the percolate. Take of this liquid one fluid ounce and estimate the amount of total alkaloid in the following way:—Evaporate almost to dryness over a water-bath, dissolve the residue in two fluid drachms of chloroform and half a fluid ounce of dilute sulphuric acid with an equal bulk of water, agitate and warm gently. When the liquids have separated draw off the chloroform and add to the acid liquid excess of solution of ammonia and half a fluid ounce of chloroform, well agitate, gently warm, and after the liquids have completely separated transfer the chloroform to a weighed dish, evaporate over a water-bath and dry for one hour at 212° F. Allow the residue of total alkaloid to cool and then weigh. Take of the percolate as much as contains $131\frac{1}{4}$ grains of total alkaloid and evaporate over a water-bath until the extract weighs two ounces. This extract will contain 15 per cent. of total alkaloid.

Ten grains of this extract when treated in the following manner should yield one and a half grains of total alkaloid. Dissolve the extract in half a fluid ounce of water with the aid of a gentle heat and add a drachm of carbonate of sodium previously dissolved in half a fluid ounce of water; add half a fluid ounce of chloroform, agitate, warm gently and separate the chloroform. Add to this half a fluid ounce of dilute sulphuric acid with an equal bulk of water, again agitate, warm and separate the acid liquid from the chloroform. To this acid liquid add now an excess of ammonia and agitate with half a fluid ounce of chloroform; when the liquids have separated transfer the chloroform to a weighed dish and evaporate the chloroform over a water-bath. Dry the residue for one hour and weigh.

[*The discussion on this and the following paper is printed at p.* 634.]

* Of course such standard extracts prepared from seeds containing different percentages of alkaloid will not have the same consistence; but this variation in consistence is not sufficiently considerable to be of any practical moment.

REPORT UPON THE PHARMACEUTICAL PREPARATIONS OF NUX VOMICA.*

(*Concluded.*)

V. THE PREPARATION OF A STANDARD TINCTURE OF NUX VOMICA

BY WYNDHAM R. DUNSTAN,

Assistant Lecturer in Chemistry and Physics to the Pharmaceutical Society and Demonstrator of Practical Chemistry in the School of Pharmacy;

AND F. W. SHORT,

Assistant Demonstrator of Practical Chemistry in the School of Pharmacy.

In the previous paper we have proposed a process for the preparation of a standard extract of nux vomica, containing 15 per cent. of total alkaloid. In considering a feasible method for preparing a standard tincture of nux vomica, we were led by our former results to two suggestions. First, the dilution with alcohol of the assayed percolate (the method of producing which has been described in the former paper) to a definite degree, corresponding to a given percentage of total alkaloid, and second, the solution of a definite quantity of the standard extract in a given volume of alcohol. We propose that the standard tincture of nux vomica shall contain 0·24 per cent. of total alkaloid, that is 1 grain of total alkaloid in 1 fluid ounce of tincture. This proposal results from a comparison of the analyses which we have already published of the various tinctures of nux vomica now being used in medicine, and represents the alkaloidal content of a good commercial specimen. The mode of preparing the standard tincture by the first method is simple in procedure and eminently satisfactory in result. An experiment was made by taking that volume of the strong percolate, assayed as before described, which contained 20 grains of total alkaloid, this was diluted to one pint with alcohol (100 : 25). A pale yellow

* Read at an Evening Meeting of the Pharmaceutical Society, February 6, 1884.

perfectly clear tincture was obtained, every ounce of which contained 1 grain of total alkaloid. This tincture did not deposit or otherwise change after being kept for one month. A practical objection perhaps attaches to this method, as one for general use, which must be allowed to have some weight. It involves the preparation of two tinctures of nux vomica, the one strong, the other weak, and the substitution of the one for the other in dispensing would be attended with grave results; this perhaps is an objection to recommending the process for general use, although it is a point on which we speak with some reserve. A number of experiments were then made in connection with the second method. It has been already shown that with ordinary extract of nux vomica there is no very easy method of obtaining a solution in alcohol which is at once perfect and permanent (*Pharm. Journ.*, [3], xiv., 442). But it now seemed probable, having prepared an extract by exhausting the nux vomica with alcohol of definite strength and evaporating on a water-bath, that such an extract would redissolve in alcohol of the same strength that had been used in its production. One gram of the standard extract of nux vomica, containing 15 per cent. of total alkaloid, was mixed with 60 cubic centimetres of alcohol (100 : 25). By stirring the whole of the extract was dissolved and the perfectly clear tincture deposited a very small quantity of a white sediment after one month.* Some of the sediment was examined and contained no alkaloid. Thus a standard tincture of nux vomica could also be readily prepared by the solution of the standard extract in alcohol of certain strength. The tincture prepared as above detailed should contain 0·24 per cent. of total alkaloid and to confirm this the tincture was assayed and yielded 0·2402 per cent. of total alkaloid, thus coinciding with the calculated result. The standard tinctures prepared by the two processes which have been described contain, of course, the same percentage of total alkaloid. They differ in colour, that prepared by the first process being pale yellow, by the second, light brown; the latter also deposits very slightly, while the former is perfectly stable. For reasons already stated, we incline to recommending the latter process for general use; the former would probably be preferred by the manufacturer upon the large scale. The following is a description of both the processes which we have devised for the preparation of a standard tincture of nux vomica containing 0·24 per cent. of total alkaloid:—

I. Take of—

Nux vomica in fine powder . . .	1 pound.
Rectified spirit	64 fl. ozs.
Distilled water	16 „

Mix the spirit with the water and make the nux vomica into a paste with one pint of the mixture. Allow this to macerate for twelve hours, then transfer to a percolator and add another pint of the mixture. When this has percolated, pour on the remainder of the diluted spirit in successive portions; press the marc, filter the expressed liquid and add it to the percolate. Take of this liquid 1 fluid ounce and estimate the amount of total alkaloid in the following way:—Evaporate almost to dryness over a water-bath, dissolve the residue in 2 fluid drachms of chloroform and half a fluid ounce of dilute sulphuric acid with an equal bulk of water; agitate and warm gently. When the liquids have separated draw off the chloroform and add to the acid liquid excess of solution of ammonia and half a fluid ounce of chloroform; well agitate, gently warm and after the liquids have completely separated transfer the chloroform to a weighed dish. Evaporate over a water bath, and dry for one hour at 212° F. Allow the residue of total alkaloid to cool and then weigh.

Take that quantity of the percolate which contains 20 grains of alkaloid and dilute to one pint with a mixture of 4 parts by volume of rectified spirit with 1 part by volume of distilled water. This tincture will contain 0·24 per cent. by volume of total alkaloid and 2 fluid ounces of it when estimated, in the same manner as the percolate, should yield 2 grains of total alkaloid.

II. Take of—

Standard extract of nux vomica .	133 grains.
Rectified spirit	16 fl. ozs.
Distilled water	4 „

Mix the spirit with the water and dissolve the extract in the mixture. One fluid ounce of this tincture will contain one grain of total alkaloid.

In concluding this the last part of the Report we wish to gratefully acknowledge the valuable assistance which we have from time to time received from Professor Redwood, who has closely followed the progress of the investigation and made many fruitful suggestions which have contributed to its successful result. We also wish again to thank Professor Attfield for having allowed the work to be carried on in the Laboratories of the Pharmaceutical Society. The investigation has been largely aided by a grant from the Research Fund of the British Pharmaceutical Conference.

* The extract, it should be noted, will not wholly dissolve in rectified spirit.

THE ASSAY OF ATROPA BELLADONNA.*

I. THE ESTIMATION OF THE ALKALOIDS IN THE ROOT OF ATROPA BELLADONNA.

BY WYNDHAM R. DUNSTAN,

Assistant Lecturer in Chemistry and Physics to the Pharmaceutical Society and Demonstrator of Practical Chemistry in the School of Pharmacy;

AND F. RANSOM.

Many methods have been proposed for the estimation of the alkaloids which exists in *Atropa Belladonna*. The majority of these methods involve the use of solvents which extract large quantities of non-alkaloidal organic substances, and thus necessitate the subsequent use of other solvents and precipitants to purify and isolate the alkaloid. A great advance was made by Pesci (*Gazzetta di Chimica Italiana*, x., 425), when he showed that the alkaloid could be extracted in a comparatively pure state by benzene from an aqueous extract of belladonna after the addition of an alkali. The benzene was then agitated with dilute sulphuric acid, which was subsequently rendered alkaline with ammonia and the alkaloid removed by chloroform. Pesci's method of extraction, although a great improvement upon older methods, was still far from perfect and obviously could not be easily applied for the estimation of the alkaloid. In a previous paper† one of us has proposed a new method in plant analysis where a body soluble in chloroform has to be isolated. This

* Read at an Evening Meeting of the Pharmaceutical Society, February 6, 1884.

† Dunstan and Short, "The Assay of Nux Vomica" (*Pharm. Journ.*, [3], xiii., 665).

method was based upon the general principle that in plant analysis that solvent should be selected for the estimation of the active constituent which extracts this constituent with the smallest quantity of the other constituents, thus rendering unnecessary long processes of subsequent purification.

There are many solvents which can be used for this purpose, solvents which easily dissolve alkaloids, glucosides, etc., but less readily dissolve colouring matter, acids, sugars, etc. Chloroform is one which often admits of use, but it was pointed out in the paper referred to that chloroform alone was ill-suited for completely extracting the plant tissues, owing to its weak penetrating power. It was also proved in the special instance of nux vomica that this difficulty could be overcome by the admixture of alcohol with the chloroform; that is to say, while chloroform alone was incapable of extracting the whole of the alkaloid from nux vomica, when mixed with 25 per cent. of alcohol it was able to do so thoroughly and completely, leaving behind the whole of the mucilaginous constituents of the seeds and the other non-alkaloidal constituents, many of which would be extracted if alcohol alone were used. In the present paper we have extended this method of extraction with the chloroform-alcohol mixture to the isolation of the atropine and hyoscyamine existing in the root of *Atropa Belladonna*.

In preliminary experiments 10 grams of very finely powdered belladonna root were extracted with chloroform alone in a Dunstan and Short's extraction apparatus. The operation continued for three hours, during which time the root had been percolated twenty successive times with 50 cubic centimetres of boiling chloroform. The percolate, which had a light brown colour, contained much alkaloid when the residue was tested with phosphotungstic acid. The marc was mixed with lime and boiled with alcohol. The alcoholic residue also gave evidence of containing abundance of alkaloid when tested with phosphotungstic acid and also by its action upon the pupil of the eye. Thus the chloroform had not completely exhausted the root of alkaloid; the experiment was again repeated, the chloroform being allowed to act for a longer time, but yet the marc contained considerably more than traces of alkaloid. The same quantity of finely powdered belladonna root was now acted upon by a mixture of equal parts of chloroform and absolute alcohol under precisely the same conditions. The percolate contained much alkaloid, but no trace could be detected in the remaining marc. This experiment was likewise repeated several times with the same result. It was thus evident that just as chloroform alone had been shown to be an inefficient extractive agent for nux vomica it was now shown that the same obtains with belladonna, and similarly as a mixture of chloroform and alcohol was an excellent solvent for the nux vomica alkaloids, so the same mixture was an equally good solvent for the alkaloidal salts in belladonna. The next experiments were made with different proportions of chloroform and alcohol. A mixture of chloroform with 25 per cent. of alcohol occupied too long a time in accomplishing complete exhaustion to allow it to be made the basis of an easy process for general use. The best results were obtained with a mixture of equal parts of chloroform and absolute alcohol, which consequently was used in further experiments. It was found necessary to use absolute alcohol on account of the action of the water contained in rectified spirit upon the belladonna, which by causing swelling of the root and consequent clogging of the apparatus, seriously impeded the progress of percolation.

In these experiments the root was exhausted at the boiling point of the solvent (60°–70° C.). Experiments were now made to see whether belladonna could be efficiently exhausted by a mixture of equal parts of chloroform and alcohol without the aid of heat; but it was found that after percolating 10 grams of the finely powdered root with 150 cubic centimetres of the mixture the marc still contained a large amount of alkaloid, and it was evident that a great quantity of the solvent would be required for complete exhaustion. This although not an insuperable objection is a practical disadvantage, and having found that the belladonna root could be so well exhausted by the boiling solvent we at once proceeded to examine the effect of a boiling mixture of chloroform and alcohol upon atropine under the conditions of our experiments, and so to discover whether the alkaloid would be injuriously affected at the boiling point of the mixture. Pure atropine was boiled for six hours in an apparatus with an upright condenser with a mixture of alcohol and chloroform. The mixture was then agitated with dilute sulphuric acid and the alkaloid recovered from the acid liquid, after the addition of ammonia, by chloroform. The following results were obtained:—

	Atropine taken.	Atropine found.
α	0·085	0·084
β	0·221	0·217
γ	0·199	0·197
δ	0·213	0·208

The small differences in these figures are obviously accounted for by experimental errors, and the results, taken in conjunction with the fact that the residues were normally crystalline, prove that atropine is not decomposed or chemically altered even when exposed for six hours at the boiling point of the solvent which is proposed for use. We were now able to proceed further in developing the process. The belladonna root was now able to be exhausted with a boiling mixture of chloroform and alcohol, and it now remained to isolate the alkaloid in a pure state from the solvent. Dilute acids were at first used for this purpose, but it was afterwards discovered that the whole of the alkaloid could be withdrawn from the chloroform-alcohol mixture by merely agitating with water; two successive treatments with water in this way sufficed to remove every trace of the alkaloids from the chloroform-alcohol mixture. The separation of the water from the mixture is instantaneous and entire if the mixture is gently warmed; nearly the whole of the colouring matter remains dissolved in the chloroform, whilst the water retains the alcohol and the alkaloidal salts. By rendering the aqueous solution alkaline with ammonia and agitating with chloroform the atropine and hyoscyamine were obtained after evaporation in an apparently pure state; that is to say, the residue was entirely soluble in dilute acids, and when dissolved in chloroform and the solvent spontaneously evaporated the alkaloid remained as a mass of white silky crystals. However, one of the most important points to be demonstrated in such investigations as these is the perfect purity of the final alkaloidal residue, and yet this is a point which is generally assumed and not proved by workers in this field.

On a previous occasion* one of us has proposed a method for ascertaining the purity of residues of strychnine and brucine, which is founded upon the complete precipitation of these alkaloids (when nearly free from other organic substances) by a solution of tannin rendered faintly alkaline with ammonia. This process was tried with atropine and hyoscyamine, but with negative results, for the precipitate at first formed was soluble in excess of the reagent. Other reagents were now experimented with. Potassium mercuric iodide was found to be by no means a complete precipitant of atropine, and is useless for its detection when present in small quantity. Picric acid is also useless alike for the detection and estimation of atropine; even when considerable quantities of the alkaloid are present in solution this reagent fails to afford any indication. Phosphotungstic and phosphomolybdic acids are far more delicate than the former reagents, but even these are not sufficiently exact for quantitative use. As far as the detection of atropine and hyoscyamine is concerned a very delicate test is the dilating action upon the eye's pupil which is distinctly yielded by mere traces of the alkaloids. After attempting the quantitative application of many of the alkaloid precipitants with no success, we found one reagent which is admirably adapted for quantitative use. A solution of iodine in potassium iodide completely precipitates even traces of atropine and hyoscyamine, from a solution in dilute hydrochloric acid, as the dark green periodides. When other acids are present the precipitation is not quite so complete. After a great number of experiments had been made with this reagent, and also in reference to the decomposition of the periodides, we devised the following method for estimating the purity of residues of atropine and hyoscyamine. The alkaloidal residue is dissolved in dilute hydrochloric acid and to this liquid is added excess of a strong solution of iodine in potassium iodide. The precipitate which at once agglomerates is filtered off, slightly washed with the solution of iodine and decomposed upon the filter with a solution of sodium thiosulphate, when it entirely dissolves, forming a colourless liquid from which the alkaloid is removed by agitation with chloroform. This process gave very satisfactory results with pure atropine and the following results were obtained with the alkaloidal residues obtained in our experiments:—

	Residue taken.	Pure alkaloid found.
1	0·020	0·0185
2	0·019	0·0175
3	0·078	0·079
4	0·078	0·076

These figures indicate that the final residue of alkaloid obtained from belladonna root by the process which we have described consists of pure alkaloid. It should be noted that both atropine and hyoscyamine are much affected by prolonged exposure at 100° C., becoming sensibly darker in colour. The residues of alkaloid obtained in the process, and which usually weigh rather less than 0·1 gram, are light yellow in colour and have a fused appearance; crystals of the alkaloids may be obtained by redissolving in chloroform and spontaneously evaporating, when silky needles will remain if the chloroform was free from water. The following is a detailed description of the process which we propose for the estimation of the atropine and hyoscyamine in belladonna root. Twenty grams of the dry and finely powdered root are exhausted by hot percolation with a mixture of equal parts by volume of chloroform and absolute alcohol; if an extraction apparatus is used about 60 c.c. of the mixture is required. The percolate is agitated with two sucessive 25 c.c. of distilled water, which are separated in the usual way. These are mixed and well agitated with chloroform to remove the last traces of mechanically adherent colouring matter. The chloroform is separated, the aqueous liquid rendered alkaline with ammonia and agitated with two successive 25 c.c. of chloroform, which are separated, mixed and agitated with a small quantity of water (rendered faintly alkaline with ammonia) to remove adherent aqueous liquid. The chloroform is then evaporated over a water-bath until the weight of the atropine and hyoscyamine is constant, which usually occupies a little less than one hour.

The special features which distinguish this process are, (1) it is simple and accurate; (2) a high temperature is avoided; (3) the solvent employed extracts a minimum of non-alkaloidal constituents; (4) no precipitants are used; (5) the use of acids is avoided; (6) the alkaloids are not heated with alkalies.

The root of *Atropa Belladonna* grown at Hitchin and carefully dried at 100° F. yielded 0·38 per cent. of total alkaloid (atropine and hyoscyamine) when estimated by this process. Other specimens estimated in the same way yielded 0·39 per cent. and 0·35 per cent. of total alkaloid.

The work connected with this investigation has been aided by a grant from the Research Fund of the British Pharmaceutical Conference. In a future communication we propose to show how this process can be applied to the estimation of the atropine and hyoscyamine in other parts of the plant.

NOTE ON A CASE OF SOPHISTICATION OF AMERICAN OIL OF TURPENTINE.*

BY BOVERTON REDWOOD, F.I.C., F.C.S.

A short time ago a sample, representing a shipment of several hundred barrels of oil of turpentine from Wilmington, was handed to me for examination by Messrs. Ingall, Phillips and Co., the wharfingers.

The odour of the sample was peculiar, and the specific gravity very high (·887). The flashing point (Abel petroleum test) was also somewhat high (96° F.). The flashing point of eleven other samples of oil of turpentine, presumably pure, imported about the same time from the United States, was 92° F., and the highest specific gravity 0·8676. Upon distillation in a current of steam the sample yielded 4 per cent. of a viscid residue, slightly heavier than water. The specific gravity of the distillate was 0·873. The residue, besides being some sixteen times greater in quantity, differed in physical characters from the residues similarly yielded by the eleven other samples just referred to. These residues ranged from 0·12 per cent. to 0·35 per cent.

I made a brief report upon the sample but was prevented, by pressure of work, from following up the matter, and I am now unable to procure a further quantity of the oil. My father has, how-

* Read at an Evening Meeting of the Pharmaceutical Society, February 6, 1884.

ever, been good enough to examine the resinous matter left upon evaporation, and with the kind assistance of Mr. Holmes to compare it with specimens in the Pharmaceutical Society's Museum, but has, I understand, not succeeded in identifying it. A distinctive feature is its persistently bitter taste.

It is worthy of remark that the sample was drawn during the landing of the cargo, and the sophistication must therefore have taken place prior to shipment. Oil of turpentine is occasionally adulterated with the crude turpentine, but the character of the residue yielded by this sample would appear to indicate that the resinous exudation from some tree other than those which furnish the American turpentine of commerce had been added. A friend engaged in the turpentine trade, who is returning to Charleston, South Carolina, this month, has promised to ascertain, if possible, what is likely to have been so employed.

THE PRESS ON THE SALE OF POISONS.

From the MEDICAL TIMES, *February* 2.

Several unfortunate cases have recently drawn attention to the facility with which poisons can be obtained, by even the least respectable persons, and many suggestions have been made with the view of preventing "accidents." But the question is not so simple as it seems. Restriction as to the sale of poisons is difficult. Noxious things are among the daily necessities of a civilized community. Phenol, oxalic acid, binoxalate of potash, and others must be retailed to the general public and to the workers in many trades without passing through the cycle of oral and written forms. If it were possible to enact and carry out a very strict Pharmacy Act, a hundred and one arts and industries, from etching on copper to washing linen, would languish. Imagine a Royal Academician desiring to purchase a tube of green paint, and having to give his name and address, to write it in a book, and to state the purposes for which he requires it! What stronger poison is there than tobacco? Half an ounce infused in water would make short work of even an inveterate smoker; but the absurdity of including tobacco in a Poisons Act is too obvious for discussion. Not a few would like to see laudanum and chloral controlled in a much more thorough manner than under the present law, but we are doubtful whether steps in this direction are really practicable. If a person will eat opium or is under the thraldom of chloral no law will prevent him, in any efficient manner, save at the expense of the general community, from purchasing what he requires. If no druggist is to sell more than a grain of opium to one person, the opium eater has but to go to twenty, thirty, or forty druggists until he has accumulated his dose. Some coroners seem to imagine that many suicides would be prevented if common poisons, such as phosphorus paste and the like, were prohibited from being sold at all; but we venture to think, that only that kind of suicide dependent on sudden impulse would be at all influenced by any greater restriction being imposed than at present. There are many doors of death; a man bent on self-destruction, stopped in one direction, succeeds in another. Remove the poison, he cuts his throat with a razor; remove knives and drugs, he suspends himself with his neckcloth.

To sell poison as poison, with a poison label on it, in a poison bottle, is one thing, but to sell it under a fancy name is another. The "soothing syrups," the "cough drops," the "remedies for spasms," the countless pills, elixirs, lotions, drops, and sleeping potions which fill the druggists' shops, and their descriptions the advertising columns of the journals, are so many public dangers. A Lepcha once described the root of a glossy lurid-leaved Himalayan plant as "useful to sportsmen for destroying elephants and tigers, useful to the rich for putting troublesome relations out of the way, and useful to jealous husbands for the purpose of destroying faithless wives." In a similar spirit, looking at the long list of patent medicines of deadly composition, we may describe them as "useful to the insurer of the lives of others, useful to the expectant heir, useful to blight the shame-bud of illicit love, useful to the farmer of babies, and useful to all who have aught human to kill." The "powder of succession" can be bought for thirteenpence-halfpenny; the "Aqua Toffana" has changed its name to "Somebody's infallible skin remedy;" the venom that smeared the Indian's arrow receives the English Government stamp, and pays the Government duty as a never-failing application for neuralgia or toothache. Let us have done with masks; sell each thing and let it be sold under its own name and no other, let soothing syrup be called "a solution of opium, dangerous to children;" let the exact strength and composition of odontalgic essences, of solutions of aconite, of chloral, etc., be stated on the label, and if wrongly stated let the offender be amenable to law. The time is ripe to say that licensed quackery should no longer be permitted in its present form; but that the ignorant and unscrupulous man who puts chloral solution in a bottle, colours it with cochineal, names it "Somnifer," or anything else that can be registered, and casts it broadcast by means of advertisement over the land, should be held responsible for its use and abuse. So long as the composition of medicines and poisons is known, so long as there is no secresy, then there is fair protection both from accidental admixture and wilful ministration; but the present sale of poisons under the guise of patent medicines is not creditable to our laws, and is alien to our method of thought. We hope that an early effort will be made to take from the speculator and the charlatan the liberty they now possess of pressing the poisoned chalice to the lips of the credulous and simple.

SYRUP OF CALCIUM LACTOPHOSPHATE.*

R. Rother has lately recommended to prepare the above-mentioned syrup by dissolving lactate of calcium with the aid of phosphoric acid instead of following the old plan of dissolving phosphate of calcium in lactic acid, and, owing to the fact that lactate of calcium is not everywhere readily obtained, has proposed a formula which provides for its extemporaneous preparation when the syrup is to be compounded.

The proportions given by the author are such that the relative proportions of calcium phosphate and lactic acid contained in the finished syrup shall be one molecule of the former to six molecules of the latter (instead of four molecules, as it happens to be in the officinal syrup):

Calcium carbonate	150	parts.
Lactic acid, sufficient, or ab. . .	360	,,
Phosphoric acid, 50 per cent. .	196	,,
Sugar	6,545	,,
Water, sufficient to make . . .	10,908	,,

Mix the lactic acid with 1500 parts of water, and gradually add the calcium carbonate. If the mixture does not become clear, warm it gently and add lactic acid drop by drop, until a transparent solution is obtained. To this add the phosphoric acid previously mixed with 1500 parts of water together with enough more water to make the whole weigh 4363 parts. Then add the sugar, and when this has dissolved, with frequent stirring, filter the syrup through paper.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 9, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTRAR'S REPORTS.

THE presentation by the Registrar to the Pharmaceutical Council, at its meeting last Wednesday, of his usual Reports on the Registers and on the Numerical Strength of the Pharmaceutical Society enables us, according to our custom for several years past, to complete the statistics commenced in our recent summary of the events of the year 1883, and to estimate the advance or otherwise made by the Society in respect to the fulfilment of its ambition to become more fully representative of the whole body of chemists and druggists. Without referring again to the details as to the examinations it will be sufficient to say that the number of Chemists and Druggists on the Register on the 31st of December, 1883, was 13,665, of whom 2248 were also included in the Register of Pharmaceutical Chemists. These figures show a considerable increase in the number of Chemists and Druggists, but a decrease of 27 in the Pharmaceutical Chemists. Although it will be necessary to use the former of these figures for purposes of comparison, nevertheless, in consequence of the imperfect manner in which the Registrars of Deaths throughout the country carry out the statutory provision as to communicating information of the death of registered Chemists and Druggists, it is impossible to say more than approximately this year what the real number of persons entitled to be on the Register is; but it is certain that the apparent increase will be considerably modified when the Registrar shall again—probably in the course of the present year—exercise the powers conferred upon him for the rectification of the Register.

As to the decrease in the number of pharmaceutical chemists, this is not unanticipated, it being due to a well-recognized cause, which will continue to operate for several years to come. However much it is to be regretted, as narrowing the class competent to become Members of the Pharmaceutical Society, it would be an exaggeration of its signification to look upon it as showing a falling off in the number of persons passing the Major examination; because, as we have pointed out in previous years—and we say it again at the risk of being thought to repeat ourselves—the class is subject to losses from deaths not only among examined men but also among upwards of seven hundred persons included in virtue of having been in business and joined the Pharmaceutical Society upwards of thirty years ago. The fact is that Pharmaceutical Chemists holding the Major certificate continue to increase, the number at the end of last year having been 1547 against 1511 twelve months previously. It follows, therefore, that Major men now constitute 11·32 per cent. of the whole body of Chemists and Druggists. Necessarily the number of persons who have qualified for registration by passing the Minor only has also increased, the number being 3508 against 3287 in the previous return. These two figures give the total number of persons on the Register in virtue of examination, which amounts now to 5055, or 36·99 per cent. of all the Chemists and Druggists in the country. Throwing these figures into a tabular form, for the sake of comparison with previous years, the result is as follows:—

	January 1, 1883.				January 1, 1884.			
	Number.		Per cent.		Number.		Per cent.	
Pharmaceutical Chemists:—								
Examined . .	1511	2275	11·24	16·92	1547	2248	11·32	16·45
Non-examined	764		5·68		701		5·13	
Chemists and Druggists who have passed the Minor only . .		3287		24·44		3508		25·67
Remainder, including those who have passed the Modified . .		7885		58·64		7909		57·88
Total		13,447		100·00		13,665		100·00

The Report of the Registrar as to the numerical strength of the Pharmaceutical Society certainly presents subjects for congratulation; for although it shows a decrease in the number of Members—21 Pharmaceutical Chemists and 17 Chemists and Druggists — the increase in the number of Associates has been more than sufficient to compensate for this in point of numbers. Indeed, not only has the retrogression that was recorded last year been recovered, but the number of registered Chemists and Druggists connected with the Pharmaceutical Society at the end of last year was within six of the highest yet attained, whilst, if Apprentices be included, the highest previous number was considerably exceeded. The decrease in the number of Members, both Pharmaceutical Chemists and Chemists and Druggists, is attributable to causes similar to that previously referred to as affecting the general Register of Pharmaceutical Chemists, and which, indeed, affect the membership of the Society in an even greater degree. But the number of Pharmaceutical Chemists who belonged to the Society as Members at the close of the year was 1882 out of a total of 2248 on the general Register, and it is worthy of notice that although only 55 persons passed the Major examination during the year 1883, 50 Pharmaceutical Chemists were elected Members and 10 restored to membership during the same time. The Associates in Business numbered 1178, showing an increase of 71 on the previous year, and the Associates 827, showing an increase of 3. The steady increase, year by year, in the important class of Associates in Business is remarkable, and points to the desirability of the provision in the Draft Pharmacy Bill that the passing of the qualifying examination shall constitute eligibility to full membership of the Society. It remains only to say that the number of Apprentices had increased from 1037 to 1098. The figures of the two years may be compared as follows:—

	January 1, 1883.		January 1, 1884.	
	No.	Per cent of whole.	No.	Per cent of whole.
Pharmaceutical Chemists, Members of the Society .	1882	82·72	1861	82·78
Other Registered Chemists and Druggists connected with the Pharmaceutical Society	2710	—	2767	—
Total number of Registered Chemists and Druggists connected with the Pharmaceutical Society. . .	4592	34·15	4628	33·89
Registered Apprentices subscribing to the Society .	1037	—	1098	—

The Registers of Pharmaceutical Chemists and Chemists and Druggists, for 1884, is now ready and copies may be obtained from the Registrar, 17, Bloomsbury Square.

* * *

In the House of Commons, on Thursday, Mr. Warton, according to notice, asked the Secretary of State for the Home Department whether his attention had been called to the case of William Henry John Heath Sheaham, aged seven months, on whose body an inquest was holden on the 31st December, 1883, by Dr. Danford Thomas, and whose death the jury found was caused by the antimony contained in a patent medicine called "Holt's Specific for Whooping-Cough;" whether he was aware that the jury did not (*sic*) desire to call attention to the sale of patent medicines, with a view to legislation on the subject; and whether it was his intention to bring in a Bill to restrict the sale of poisonous patent medicines. The question was replied to by the Vice-President of the Committee of Education of the Privy Council (Mr. Mundella), who said that the attention of the Privy Council had been directed to this and two other similar cases, and that a Bill was under consideration, which would be introduced shortly in the House of Lords, dealing with the whole subject. Mr. Warton's question was no doubt asked as *à propos* of the fact that a "Bill to restrict the Sale of Patent Medicines" had been introduced by him in the House of Commons on the previous evening and read a first time. This Bill has not yet been printed, but the second reading is set down for the 26th of March.

* * *

A Bill dealing with this subject has been introduced into the United States House of Representatives containing provisions that appear to have disturbed the equanimity of transatlantic patent medicine dealers. It proposes to make it illegal for the post office authorities to include in the mails any advertisement or advertising device of "any medical preparation, compound or prescription, or any punch, bitters, cordial or similar compound or preparation to be used as medicine or mixed with food, liquor, wine or any other substance used as a beverage or as food or medicine," until the exact formula for the preparation of the article advertised has been deposited, together with a sample, in the Patent Office, and a certificate has been issued by examiners appointed for the purpose that the article is not noxious or dangerous to health. As such a provision, if carried out stringently, would exclude nearly all newspapers from postal privileges or necessitate a radical alteration in their advertising columns involving, it is estimated, a probable annual loss to the proprietors of at least a million sterling, it will be interesting to observe the attitude of the public press in the States towards the Bill.

* * *

A Bill providing for the registration of firms and of persons carrying on business under names and styles other than their own was read a first time in the House of Commons on Wednesday last, and the second reading is set down for the 3rd of March. The Bill was brought in by Mr. Norwood.

* * *

The new Rules for the Registration of Trade Marks, with Classification of Goods and Table of Fees, were on Tuesday, in accordance with the terms of the Patent Act, laid before Parliament. It may be useful to state that a pretty full abstract of this paper is printed in the new Calendar of the Pharmaceutical Society.

* * *

A curious case, involving the question as to how far unqualified persons can hold property in pharmacies in France, has been recently before the Cour de Paris. It seems that a pharmacien who had opened a pharmacy, not being successful, disposed of the business to a company, including unqualified persons, by whom he was employed as manager. This mode of carrying on a pharmacy was, however, objected to by the Société de Prevoyance des Pharmaciens de la Seine, which, more fortunate than the Pharmaceutical Society in this country in similar circumstances, succeeded in obtaining a legal judgment which put a stop to it. The baulked company then proceeded to dispose of the business to a pharmacien, but here the creditors of the founder of the establishment intervened, and on the plea that as the company could not legally carry on the business the first sale was not a valid one claimed the business as part of the defaulter's estate. This claim has not been allowed by the Court, and it would, therefore, appear that in France an unqualified person may become the proprietor of a pharmacy, but that whilst it continues in his possession the business must not be carried on.

* * *

The enormous proportions attained by the glucose industry in the United States, and probably some disquieting rumours that have found currency concerning the wholesomeness of the product, appear to have induced the American Commissioner of Inland Revenue to ask the aid of the National Academy of Sciences in investigating the subject. The Academy entrusted the inquiry to a Committee, which has recently reported its opinion that the processes at present employed in the manufacture of sugar from starch are unobjectionable and leave the product uncontaminated; that the starch sugar thus made and sent into commerce is pure and uniform in composition and contains no injurious substances; and that although possessing, at most, only two-thirds of the sweetening power of cane sugar, nevertheless, starch sugar is not inferior to it in healthfulness, no evidence having been met with that maize starch sugar, either in its normal condition or when fermented, has any deleterious effect upon the constitution even when taken in large quantities.

* * *

In a paper contributed to the new number of the *Journal de Pharmacie*, M. Lepage mentions that in the performance of his duties as an inspector of pharmacies he has frequently met with specimens of aqueous extract of cinchona which failed to give evidence of containing more than traces of alkaloid. Seeking an explanation he found that in order to meet a requirement on the part of certain physicians that the extract should be completely soluble in water it was frequently prepared with cold water instead of the boiling water ordered in the Codex. In a similar manner the alcoholic extracts of belladonna and henbane are said to be supplanted by what are really aqueous extracts, containing hardly any alkaloid.

* * *

According to *Nature* it was announced at the last meeting of the Vienna Physical Society that Professor von Wroblewski has succeeded in effecting the solidification of hydrogen.

* * *

The gold medal offered annually by the Paris Society of Pharmacy for the best thesis on a subject belonging to natural or chemical science has recently been awarded to M. Anthoine for a memoir on "The Anhydrides and Mixed Anhydrides of Acetic Acid and Chlorated Acetic Acids."

* * *

The *Bulletin Commercial* publishes a curious genealogical fragment, based upon extracts from municipal archives, showing that during six consecutive generations of a family named Baudot, the occupancy of a pharmacy in Langres (department of Haute-Marne) has passed from father to son without any break. The family occupation extended over nearly two centuries.

* * *

We regret to say that information has been received of the death on the 28th of January, from bronchitis, of Mr. Henry Edward Davies, who was elected an annuitant in 1883.

* * *

The Third Junior Pharmacy Ball took place at Willis's Rooms, on Wednesday last, and was in every respect successful, the company numbering about three hundred and sixty. The toasts were proposed by Professor Attfield, F.R.S.

* * *

The annual dinner of the Chemists' Assistants' Association is to take place at the Holborn Restaurant on Wednesday, February 20. S. R. Atkins, Esq. (Vice-President of the Pharmaceutical Society), in the chair. Information as to tickets, which should be applied for at once, will be found in an advertisement on another page.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, 13th inst., at 9 p.m., when a paper on "The Human Eye" will be read by W. J. Frankish, Esq., M.R.C.S.E.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, February 6, 1884.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Andrews, Bottle, Butt, Churchill, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

Members of the Council who Retire.

The lot having been taken in the usual manner to determine the seven members of the Council who should retire in May next, the following names were drawn:—

Atkins.	Radley.	Savage.
Borland.	Robbins.	Woolley.
Butt.		

The following, who remained in by lot last year, now retire by rotation:—

Churchill.	Schacht.	Williams.
Gostling.	Squire.	Young.
Greenish.		

The following remain in office another year:—

Andrews.	Hampson.	Richardson.
Bottle.	Hills.	Symes.
Carteighe.		

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following pharmaceutical chemists, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Allsworth, Norman ....London.
Dymond, Thomas Southall......Enfield.
Gulliver, Walter Frederick......London.
Ivatt, Albert......................Cambridge.
Jones, Frank......................Royton.
Jones, William....................London.
Longtoft, William ....London.

Chemists and Druggists.

The following registered chemists and druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Brookes, George ....Llandudno.
Robb, John ....Cardiff.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society.

Minor.

Bradford, George Henry.........Bridlington Quay.
Hill, Richard Mainprize ....Scarborough.
Innes, David.......................Stalybridge.
Penberthy, Henry Broad ......Sidmouth.
Quick, William Thomas ....Lympstone.
Sanderson, Edward John ......Hazel Grove.

ASSOCIATES.

The following, having passed the Minor examination and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Buchanan, John ....Bonnyrigg.
Cairns, John ....Kelso.
Coats, John Thomson ....Edinburgh.
Dorning, Herbert Rigby.........Chorley.
Flett, Arthur ....Edinburgh.
Harrison, John......................Lincoln.
Hogg, Henry Scott ....Glasgow.
Jack, James ....Arbroath.
Mackenzie, James Calder ......Grantown.
Millhouse, Edward ....Grantham.
Smith, Charles Albert ....Leeds.
Steward, Josiah William.........Bridgnorth.
Tookey, Edwin James.............Birmingham.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Adams, Anthony Allan ....Salcombe.
Anderson, James Grant ....Aberdeen.
Andrew, John Herbert ....Oldham.
Arnold, John Julius ....Brighton.
Atherton, Henry C.................Tunbridge Wells.
Atkinson, William George......Ulverston.
Baker, Sidney George ....High Barnet

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Restorations to the Register.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

James Palliser Douglas, 99, East Street, Southampton.
Willam Hudson, The Willows, Upper Mitcham, Surrey.

The Registrar's Report.

The usual report by the Registrar upon the numerical strength of the Society, the statistics of the examinations and the Registers, was laid upon the table and ordered to be published. The report is printed on pp. 632 and 633.

Reports of Committees.

FINANCE.

Upon the motion of the President, the report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

Mr. Schacht congratulated the Council that the President had arranged to take the chair on the previous day at the meeting of this Committee, and had thus conveyed to the Committee his approbation of the suggestion recently made that the President or Vice-President should take the chair at all meetings of the Finance Committee. It occurred to most then present that it was very desirable, if the President could make it convenient to do so, that he should take the chair, because he could carry on with more perfect continuity than any one else the story of the expenditure of the Society. Many reasons might be mentioned for the desirability of this arrangement, but he would only mention one, viz., that from time to time many questions of expenditure came forward which had to be dealt with on the authority of the President in the first instance; they would come before the Committee afterwards, and it was very desirable that the President should be present and give such explanations as might appear necessary. Hitherto the President had generally given his attention to the

Benevolent Fund Committee, which sat at the same time, but it appeared to him that that Committee might be quite as well presided over by the Vice-President.

The PRESIDENT said he had no doubt that the Vice-President and himself would be able to arrange satisfactorily for the work of these two Committees.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a former member, aged 68 (who has had nine previous grants), suffering from chronic disease. Sussex.

£10 to the widow of a registered chemist and druggist, aged 38. Applicant had £10 in February, 1883. Husband died in 1882 leaving her with seven young children, one of whom has since died. Essex.

£5 to the widow of a registered chemist and druggist, aged 60. Applicant has had four previous grants, is in ill-health and dependent for support upon two sons; has also two daughters. Middlesex.

£10 to a registered chemist and druggist, aged 74. Had a grant of £10 in May last. Too old and feeble to earn anything. Sussex.

Several other applications had been received, which the Committee declined to entertain.

The Secretary had reported that he had expended fifteen out of the twenty guineas granted last month for the purpose of securing the election of a child to the London Orphan Asylum, and had been successful. The death of Mr. Davies, one of the annuitants, had been reported.

The Council went into committee while an explanation was given as to one of the applications which had not been entertained. In the course of the discussion which ensued, several members commented on the new regulations introduced with regard to signing the papers of application, the opinions expressed being very divergent. The only point necessary to refer to is one mentioned by Mr. Butt, viz., that applicants should not rest satisfied with the two signatures actually required, but should get their applications supported as influentially as possible.

On resuming, the report and recommendations were, on the motion of the Vice-President, unanimously adopted.

Donations to the Benevolent Fund.

The PRESIDENT announced the receipt of the following handsome donations:—

Mr. Buck, Stamford Hill, £105.
Miss Humpage, in memory of her late father, Mr. Benjamin Humpage, Chiswick, £50.
Mr. Charles Maw, Aldersgate Street, £105.
Mr. C. T. Maw, Aldersgate Street, £26 5s.

The special thanks of the Council were voted to the donors.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
December	Day	328	26	2	14
	Evening	138	20	4	9
Year 1883	Day	6011	40	0	20
	Evening	1764	20	1	8

	No. of Entries.		
Circulation of books.	Town.	Country.	Total.
December	130	92	222
Year 1883	1866	1374	3240

Carriage paid.	£	s.	d.
December	1	6	11
Year 1883	20	4	2½

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Eder (J. M.), The Chemical Effect of the Spectrum, 1883. From Capt. ABNEY [?].

Society of Medical Officers of Health, Transactions, 1882-3. From the SOCIETY.

Meyer (A.), Handbuch der qualitativen chemischen Analyse, 1884. From the AUTHOR.

Attfield (J.), Chemistry, 10th [U. S.] ed., 1883. From the AUTHOR.

Gay (H. F. F.), Étude Micrographique et Spectroscopique des Teintures et des Alcoolatures et en particulier des Teintures d'Opium, 1883. From Professor SOUBEIRAN [?].

Companion to the British Homœopathic Pharmacopœia, 2nd ed., 1883. From Messrs. KEENE and ASHWELL.

The Committee recommended the purchase of the undermentioned works:—

Bleaching, Dyeing, and Calico Printing (Churchill's Technological Handbooks), 1884.

Kohlrausch (F.), Introduction to Physical Measurements, 1883.

Kilner (W. B.), Compendium of Modern Pharmacy, 5th ed., 1884.

Curator's Report.

The Curator had reported the attendance in the Museum to have been:—

	Total.	Highest.	Lowest.	Average.
Morning	399	37	2	18
Evening	110	16	0	5

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimens of Hydroxylamine, Hydroxylamine Hydrochloride and Hydroxylamine Sulphate. From Mr. W. H. INCE.

Specimens of Chian Turpentine and Mastic from the Island of Scio, a fine specimen of Gum Arabic and of Scammony Resin. From Mr. ZANNI, of Constantinople, presented through Mr. T. GREENISH.

Specimens of Paraffinum Solidum, and Paraffinum Liquidum, Unguentum Paraffinum, and Adepsine. From KARL HELLFRISCH and Co., Offenbach-on-the-Maine.

Specimens of the seeds of Cassia occidentalis and of a root from Africa resembling Pareira Brava. From Mr. G. C. MACWILLIAMS.

Specimens of Tinguaciba Bark and of Bark of the Balsam of Peru tree. From Messrs. T. CHRISTY and Co.

A letter had been received from the Superintendent of the Royal Botanic Gardens, Calcutta, reporting the dispatch of further specimens of cinchona bark, analyses of which were enclosed.

The Professors had reported satisfactorily of their respective classes.

The Committee had considered the question of securing additional premises in Edinburgh, the accommodation being insufficient on examination days, and recommended that a suitable house be secured at the first convenient opportunity.

The PRESIDENT, in moving the adoption of the report, having referred to the value of the specimens of bark which were being presented to the Society, suggested that the Council should go into committee for the purpose of considering the last paragraph of the report, referring to the premises of the North British Branch.

This being acceded to,

The PRESIDENT explained in detail the reasons which had weighed with the Committee in the recommendation it had made. He stated that the present premises in George Street, though in many respects suitable, were defective in regard to the approach, and also in sanitary arrangements, which on days of examination was found very inconvenient. It had been suggested that it would answer the purposes of the Society better to purchase a house suitable to its requirements, and inquiries having

been made, it was found that the Society would be put to little or no extra expense by so doing; whilst if a larger house than was at present requisite were acquired, no difficulty would be found in sub-letting a portion of it.

Mr. YOUNG gave further information of a similar character.

On resuming, the report and recommendations of the Committee were received and adopted unanimously.

GENERAL PURPOSES.

The report of this Committee included the usual letter from the Solicitor, reporting upon the progress of cases in his hands. In most cases great difficulty had been found in obtaining the evidence required. Two other cases of alleged infringement of the Pharmacy Act had been considered, and it was recommended that the Solicitor be instructed to commence proceedings.

The Council went into committee to consider the report.

On resuming, the report and recommendations of the Committee were received and adopted.

LAW AND PARLIAMENTARY.

The report of this Committee stated that at the last meeting the President and Vice-President of the Chemists and Druggists' Trade Association had been present by invitation when the provisions of the Bill were discussed and explained. The Secretary had been subsequently directed to write to the Secretary of the Trade Association, inviting the Executive to appoint a small deputation to join one from the Council in waiting on the Lord President of the Privy Council. A reply had been received stating that the matter would be brought before the Executive of the Trade Association at its next meeting on the 8th inst.

The Council went into committee to discuss the report.

On resuming, it was received and adopted.

REPORT OF EXAMINATIONS.

PRELIMINARY EXAMINATION.

	Candidates. Examined.	Passed.	Failed
January 8th.	278	127	151

Six certificates received in lieu of the Society's Preliminary examination.

1 College of Preceptors.
3 University of Cambridge.
2 „ „ Oxford.

Mr. SCHACHT said some figures had been put into his hands with regard to the last Preliminary examination, to which he should like to call attention. They showed that the examination was extremely exact for its purpose, inasmuch as a candidate whose general education had been good, who had been well trained, but who went in for this examination without any sort of special training, succeeded in obtaining nearly the maximum number of marks.

Mr. HILLS was much interested in this report (published on p. 613), but regretted to find that arithmetic was still the plucking subject. He considered it the most important subject of the three, seeing how requisite it was that prescriptions should be exactly dispensed, even from the point of view of the safety of the public. He found that out of 151 failures no less than 65 were in arithmetic alone.

CORONER'S JURIES.

The PRESIDENT said the Council had no doubt read a note in the Journal containing some strong statements made at a coroner's inquest with regard to the exemption of pharmaceutical chemists from service on such juries. Without going into details he might say that on his attention being called to the subject he at once communicated with the Solicitor, who, subsequently, had an interview with the Coroner, and there was every reason to hope that the contingency referred to would not arise. Of course he would not assert anything positively, but the opinion of the Solicitor was, that in the case of pharmaceutical chemists the exemption was complete, and if any pharmaceutical chemist should get into any difficulty on this point he hoped he would at once communicate with the Secretary.

Mr. SAVAGE said he had written to the gentleman referred to on seeing the report in the local paper, telling him that it was his duty to see that his name was not included in the list of persons liable to serve on juries.

The PRESIDENT remarked that coroners did not summon by any jury list; they could summon any householder, or even a person in the street, if necessary; but in the case of pharmaceutical chemists the exemption clause contained the words "all inquests whatsoever," and they claimed to be exempt. He would therefore mention that pharmaceutical chemists were exempt, not for their own personal convenience, but that the safety of the public might not be endangered during their absence from their pharmacies.

Mr. ANDREWS said he was summoned a short time ago on an inquest and the coroner told him that he did not read the Act in the same way as he (Mr. Andrews) did. On that occasion he remained at the request of the coroner as a matter of courtesy; but there was no doubt that coroners did not consider that their courts were governed by the same rules as applied to ordinary jury service.

The PRESIDENT said that was quite correct; and, curiously, the exemption of medical men, solicitors, barristers and others, only extended to ordinary juries; but in the case of pharmaceutical chemists and solicitors' clerks the clause contained the words "all inquests whatsoever," and he, therefore, thought they were exempt from service.

ADDENDUM.—Page 612, col. i, line 6, in the list of examiners present at the meeting of the Board in Edinburgh, *after* Gilmour, *insert* Kinninmont.

EVENING MEETING.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT, IN THE CHAIR.

The Fourth Evening Meeting of the Session was held, on Wednesday, February 6, the chair being taken at half-past eight o'clock.

The minutes of the previous meeting were read and confirmed.

Two papers were then read, constituting Parts IV. and V. of a Report on the Pharmaceutical Preparations of Nux Vomica, which were entitled—

IV. THE PREPARATION OF A STANDARD EXTRACT OF NUX VOMICA.

V. THE PREPARATION OF A STANDARD TINCTURE OF NUX VOMICA.

BY WYNDHAM R. DUNSTAN AND F. W. SHORT.

The papers are printed on pp. 621 and 622, and gave rise to the following discussion:—

The VICE-PRESIDENT said that the papers had struck him as essentially valuable on account of their practical nature. However important it was that, at times, they should pass into the region of abstract speculation and original research in pure chemistry, he took it that it was highly important in that room that they should have papers which were essentially practical. It further occurred to him that the papers were a very valuable contribution upon the subject of preparations of absolutely definite or standard strength. They had been going on in the belief that the preparations which they had been dispensing had approximated to a greater degree of uniformity than they evidently possessed. The authors set forth a by no means difficult process by which they could obtain an extract containing a total of 15 per cent. of the alkaloids strychnine and brucine and a standard tincture containing 1 grain of total alkaloid to the ounce. The obtaining of such preparations was in itself an important contribution to pharmaceutical science.

Mr. Schacht said that within the last few weeks it had been his duty, in the ordinary course of business, to prepare a fresh batch of the extract of nux vomica and he had availed himself of the valuable suggestions contained in previous papers written by the same authors. Instead of using pure spirit, he had employed the proportion of spirit and water which they had recommended as the best solvent for the powerful ingredients of nux vomica. He operated upon a quantity of seven pounds of nux vomica, and he proceeded by the old-fashioned process of softening the material by steam and then drying it and putting it into a mill and grinding it. By this means he easily obtained a very nice powder, and this was exhausted by percolation in the most simple of all apparatus. The percolation was continued until there was no sign of colour, or very little. His experience had differed somewhat from that of these extremely careful experimenters. He had found that something like 43 pints of the diluted alcohol were required to exhaust the 7 pounds of nux-vomica. That the materials were thus very nearly exhausted he found by putting them afterwards into boiling alcohol, and thoroughly boiling them, the result of which process was that he got only 3 drachms more out of the whole 7 pounds. The operation yielded 36 pints of tincture, and that being evaporated under conditions for saving the spirit yielded him ultimately 14 ounces of extract. Unfortunately, the process was not completed until Friday last, and the time which had elapsed since had not sufficed for him to be able to ascertain the proportion of alkaloids in a satisfactory way. He almost thought that a larger proportion would be yielded than Mr. Dunstan had found in the other cases. If it was true that nux vomica contained nearly 3 per cent. of total alkaloids, 7 pounds ought to yield about 3·42 ounces total alkaloids. If the extract contained the whole, then 14 ounces ought to contain 3·42 ounces of alkaloid, nearly 3½ ounces, which was about 24 per cent., and therefore a good deal more than 15 per cent. He had no intention of criticizing the results in the paper. They were, no doubt, extremely accurate, but he should like the authors to say whether the practical experiments of a commonplace pharmacist corresponded with their own. Mr. Dunstan had a proper anxiety to indicate a standard strength for the extract, but if he took a certain quantity of tincture of known alkaloidal value and evaporated it to an extract which should have a strength corresponding to a standard, how did he manage when he got it to that condition beyond which it must not be evaporated? He might add something to dilute it, but that would be the admission of a practice which he (Mr. Schacht) should not like to encourage. The dilution of a specific preparation seemed to be a dangerous thing to admit with authority. On the other hand, supposing that the extract, when prepared by commonplace pharmacists, contained 20 per cent., he should like to know what right anybody had to say that it should contain only 15. He must ask that the question of the standards be an open question. Again, supposing that the extract contained even 15 or 20 per cent., he thought that the Pharmacopœia authorities ought to modify in another edition that portion of the book which gave the doses. The Pharmacopœia declared a dose of extract of nux vomica to be from ½ a grain to 2 grains; but 2 grains of an extract, which contained 20 or 24 per cent. of strychnine and brucine, was a little outside what it was wise to prescribe upon authority.

Mr. Martindale said that he supposed that the papers were written in prospect of the introduction of a new Pharmacopœia. The standard strength which Mr. Dunstan proposed was that of 1 grain to the ounce. He (Mr. Martindale) had hoped that they were coming somewhat more nearly to the metrical system. One grain to the ounce was not a good proportion. He recommended 1 in 500, or something like that. In the new Pharmacopœia they ought to approximate more nearly to a scientific scale of weights and measures rather than continue the old system.

Mr. Robbins said that in reading the paper he had thought that a smaller quantity of spirit might be employed. He had found in practice that less than the usual quantity might be used. If he had been going to make the experiment of Mr. Schacht he should have divided the nux vomica into four parts, and placed each part in a separate percolator. After passing a relatively small quantity of menstruum through the first percolator he would use the percolate as a menstruum for the second, and so on until practical exhaustion was effected. The advantage of adopting the method which he advocated was that in the case of many substances almost a fluid extract would be obtained at the beginning, and all that would be wanted would be to get out the washings carefully from the different percolators. That being a solution which did not contain a very large quantity of extract it could be evaporated by itself, and the whole extract would be produced almost without any heat at all. By this process a very much smaller than the usual quantity of spirit would be sufficient. He adopted the process many years ago, and he had always found it successful.

Mr. Giles said that experience had taught him that a discussion on percolation was very much like percolation itself; it went on for ever. As to the details of the paper, he thought that it was relatively excessively immaterial whether the standard taken was 15 or 25 per cent., and whether they adopted the metrical system or the old system of ounces. But he did think that there was something in the paper which marked it as an era in pharmacy. It was the first overt step which had been taken in the direction of standardizing the important pharmaceutical preparations to which allusion had been made. It required very little prescience to foresee that the special feature of pharmacy in the future would be the standardizing of its preparations. Medical science had become more scientific, and in becoming more scientific it had become more exact; and it demanded a corresponding precision on the part of pharmacy. If pharmacists failed to supply that demand, they must consent to admit themselves a failure; and he believed that the consequences would be that medical practitioners would be thrown back, in spite of themselves, upon the alkaloids, although he and most practitioners believed that the pharmaceutical preparations of the drugs were more efficacious than the alkaloids. If that was done, it would, he thought, amount almost to the abolition of pharmacy, and in the place of pharmacists there would be mere dispensers of drugs who would be simply carrying on the most mechanical and the least honorable parts of the functions of pharmacists, namely, the dispensing of medicines from things which they had bought elsewhere. He thought that that would be very much to be deplored, and that the Society ought to encourage in every way measures which would tend to prevent that result, and unquestionably the development of the idea of standardizing pharmaceutical preparations was a means by which that should be achieved. He was sure that they would feel that it was a very satisfactory thing to have had a series of such excellent papers which had culminated in the very practical one which had been read that evening. The papers which had been brought forward lately had been produced by the alumni of the Society. He trusted that, quite independently of any organization or anything else, there might be a prosecution of further research in the same direction by Mr. Dunstan and his very able and careful coadjutors. He did not know that anything had given him greater pleasure than seeing the subject taken up in such a masterly way, and pursued with so much perseverance as was exhibited in the present series of papers. He had no doubt that the present paper would make its mark in pharmacy, and that the result of it would be seen in some shape or form in the forthcoming edition of the Pharmacopœia.

Mr. Bland asked whether there was any means of getting rid of the fixed oil which extract of nux vomica contained. He had found it to be a great nuisance. He believed that it was one of the principal causes of the greasy deposit which was generally found in the bottles if the tincture was kept.

Mr. Greenish said that he concluded that Mr. Dunstan used the powdered nux vomica of commerce.

Mr. Dunstan: Yes.

Mr. Greenish, continuing, said that Mr. Schacht appeared to have ground the nux vomica for himself. That being the case, he should quite expect that Mr. Schacht's result would be a larger quantity of extract than Mr. Dunstan obtained. He could not regard the powdered nux vomica of commerce as the best form from which to prepare the extract.

Mr. Tanner said that he had long regarded the powdered nux vomica of commerce as being a true and genuine article. Mr. Schacht obtained something over 10 per cent. of extract. He (Mr. Tanner) generally obtained 10 per cent. of extract in operating by the Pharmacopœia process upon powdered commercial nux vomica. This quantity agreed very closely with what Mr. Schacht obtained from the material he ground himself. With regard to the adoption of the metrical system, 1 grain to the ounce, taking the specific gravity of nux vomica, was not very far from a quarter per cent., and, therefore, it would be easily expressed metrically.

Mr. Groves said that it was very important that so dangerous a body as nux vomica should become the subject of titration. The doctors in his neighbourhood did not demand titrated drugs. Perhaps in this enlightened centre there was some demand for them. It seemed to him that the only way of titrating a body to obtain a standard article would be to prepare two substances, one decidedly above the standard and one decidely below, and then, after arithmetical calculation, to mix the two to bring the bulk to the proper standard. The paper did not discriminate between the strychnine and the brucine; it simply indicated the total alkaloids. He did not think that the object in view would be gained until such a discrimination was made. He might be allowed to express his sincere admiration of the labours of the authors. They had brought great credit to themselves and shed a lustre on the School of the Society.

Mr. Schacht said that he took no means whatever to separate the fat; but it must be remembered that he made his preparation with a spirit which was not quite as strong as the Pharmacopœia directed.

Mr. Dunstan, in reply, expressed his gratitude for Mr. Schacht's elaborate criticism, because it came from such a distinguished practical pharmacist. With regard to the percentage of alkaloid in the extract, he must know how much alkaloid was contained in the nux vomica or in the percolate before he could say what would be the probable amount in the extract. He should predict that the extract would contain about 15 per cent., but he would very gladly assay it for Mr. Schacht. Nux vomica beans usually contained from 2½ to 3 per cent. of alkaloid. The Bombay beans contained from 3½ to 4 per cent., but they very seldom came into retail pharmacy. Mr. Schacht had used much more spirit than was recommended in the paper. Nux vomica was not a very expensive substance, and Mr. Short and he had thought that the leaving in of a grain or a grain and a half of the alkaloid was not a very important matter. The fourth fraction mentioned in the paper yielded 3 grains of total alkaloid. The fifth fraction would have given still less. There was no objection to the use of more spirit except on grounds of economy. Mr. Schacht had asked what was to be done when, after evaporation, the extract was too strong in alkaloid. Mr. Short and he had noticed in preparing extracts that the proportion of extractive matter to alkaloid appeared to be fairly constant in different specimens of nux vomica containing varying amounts of alkaloid, so that the standard extract was never too soft or too hard for use.

Mr. Schacht asked how they stopped at the exact moment when the extract contained the proper amount of alkaloid. The extract might be too soft.

Mr. Dunstan said that, practically, that would never take place if their directions were followed. The finished extracts contained exactly the same amount of alkaloid, and if their process were followed, would never be too soft.

Mr. Giles said he understood that Mr. Dunstan found that some nux vomica contained 3·3 per cent. of alkaloid, and some contained 2·6 per cent. of alkaloid; but, as a matter of fact, the one which contained 3·3 per cent. yielded extract in about the proportion of 3·3 per cent.; and the one which contained 2·6 per cent. of alkaloid yielded extract in about the proportion of 2·6 per cent.

Mr. Dunstan said that that was exactly what he meant. It was a very fortunate thing that it happened to be so in the case of nux vomica, for it had lightened their work. If it had been otherwise other considerations would have had to be taken into account. Mr. Schacht had asked why 15 per cent. had been chosen, and why the strength of commercial specimens should be taken into account. The reason was that in the case of potent drugs, like extract and tincture of nux vomica, it would be extremely dangerous to change their alkaloidal strength. Some medical men would still go on prescribing the same quantities, and serious results would ensue. He believed that some difficulty occurred in the United States through an alteration of the strength of the preparations of opium. He agreed with Mr. Martindale's remarks with reference to the metrical system, but he had reason to believe that they would not see the metrical system introduced in the next Pharmacopœia. For that reason he had described the process in "official phraseology." As to the actual method of preparing the extract, of which Mr. Robbins had spoken, he (Mr. Dunstan) did not think that it was very material what process of extraction was used, and it might be very well left to the manufacturers, but the method that they had proposed seemed to be a desirable one for use on a small scale. He must thank Mr. Giles for the kind way in which he had spoken of their work. It seemed to him extremely important to have pharmaceutical preparations of definite alkaloidal strength, especially in the case of such a drug as nux vomica. He hardly agreed with Mr. Greenish with reference to the powdered nux vomica. Mr. Short and he had examined a great number of commercial specimens, both powdered and unpowdered, and they found that the percentages of alkaloid coincided pretty closely. One might safely say that powdered nux vomica was free from adulteration. Mr. Groves had raised the important point of the discrimination of the alkaloids. There were certain practical difficulties in the way of proposing a separation for general use. A skilled chemist would be required to work so delicate a method, and, although the proportions of brucine and strychnine varied somewhat in different samples, the medicine was given in such small doses that the variation was unimportant. As to the fixed oil, the extract prepared with the diluted spirit would contain less of the oil than the extract prepared with rectified spirit according to the British Pharmacopœia.

The President said that, like Mr. Giles, he hoped that the work which had been done by those two eminent workers, who had so well proved their qualifications, might be continued in other directions. He was proud to see that not only the work had been done by students of the Society's School, but that it had been done partly with the aid of the excellent research fund of the British Pharmaceutical Conference.

A paper was then read on—

The Estimation of the Alkaloids in the Root of the Atropa Belladonna.

BY WYNDHAM R. DUNSTAN AND F. RANSOM.

The paper is printed on p. 623, and gave rise to the following discussion:—

Mr. Luff said that in the assay of a substance it was extremely important that the workers should ascertain that the alkaloid which they extracted was pure. He did not think that the authors had made good that point. They took a certain amount of pure atropine and boiled it with spirit and chloroform, and extracted the alkaloid, and found the same amount as that with which they started; but they had not shown that it was the same alkaloid. His experience was that they could not boil an alkaloid in spirit without decomposing it. Saponification took place, and the alkaloid decomposed into another base and possibly an acid. An organic analysis was required to prove whether the alkaloid was the same as that with which they started. The percentages of carbon, hydrogen and nitrogen must be determined. Some years ago Mr. Groves left some aconitine in contact with ammonia and it disappeared. Dr. Wright and he (Mr. Luff) showed in later years that the aconitine had been converted into benzoate of ammonia and into another alkaloid, namely, aconine. The aconine might be about the same weight as the aconitine originally operated upon, because it had taken up water, and the water which was accreted might make up for the benzoic acid which was excreted. The aconine had, however, entirely different physiological functions from the aconitine, and was barely poisonous at all. He had taken a tolerably large dose of it. The experiments in the paper were comparative ones, and the old saying that comparisons were odious might be applied to them. During the two years that Dr. Wright and he were working upon alkaloids, he made more than two hundred organic analyses, which had never been mentioned in the papers, simply for the purpose of seeing whether the alkaloid they were working upon was a pure one or not.

Mr. Gerrard said that he was glad to hear the paper read that evening, more especially as he had taken considerable interest in the extraction of the alkaloids and active principles of plants; and he was now engaged in a research upon belladonna which was being aided by a grant from the Pharmaceutical Conference. He took exception to the remarks made by Mr. Luff as to the saponification of atropine when it was brought into contact with alcohol. He believed that there was no change whatever, and that manufacturers employed hot alcohol for the purpose of extracting atropine and hyoscyamine from the belladonna plant. He should have liked to hear from Mr. Dunstan that he had made some comparative experiments with other solvents than mixtures of alcohol and chloroform, for instance, with alcohol alone, for it seemed to be demonstrated in the paper that the more he increased the alcohol in the mixture the greater was the solvent power upon the alkaloidal constituents. The advantage shown in the paper was that by Mr. Dunstan's method there was not so much colouring matter got out as when alcohol alone was the solvent; but, notwithstanding that, he was of opinion that alcohol alone was the best solvent for the extraction of the alkaloids from the belladonna plant. In this opinion he was backed up by experiments which he had made. In the paper it was remarked that other workers assumed their products to be pure, while the authors had proved their own to be so. He should like to ask the authors of the paper what evidence they had upon that point. When the root was extracted with chloroform and alcohol there was a small amount of brown colouring matter, and even when that was shaken again with water there was some colouring matter in the aqueous solution. Therefore he considered that the figures which were given could not be taken to represent absolute atropine. The authors also stated that they used no precipitants, and that was claimed as one advantage of the process. But what was ammonia but a precipitant of an alkaloid. In another part of the paper it was shown that a solution of iodine in iodide of potassium had been used as a precipitant. Within the last year he had examined a considerable number of samples of belladonna root and leaf by a very simple method. He exhausted the belladonna with boiling alcohol, and removed the alcohol by evaporation or distillation. Of course the residue was highly coloured, and contained a good deal more than atropine and hyoscyamine. He diluted with sufficient water to obtain a clear solution. The clear aqueous solution was poured off, and the residue was well washed. A considerable quantity of the colouring matter was thus got rid of, and he then had the salts of atropine in a pale brown solution. To this solution he added ammonia in excess, and shook it with a good volume of chloroform, chloroform being by far the best solvent of free atropine. On the separation of the chloroform, and after evaporation, he obtained his residue of alkaloid containing colouring matter. Whatever was alkaline in that residue must be alkaloid, and the alkaloid must be atropine or hyoscyamine. He prepared a standard solution of sulphuric acid, 100 parts of which should exactly neutralize 1 grain of atropine. He added the dilute sulphuric acid to the residue until he got a slightly acid reaction. Every hundred minims of the dilute acid equalled 1 grain of atropine or hyoscyamine, as the case might be. The results of that process were as scientifically exact as it was possible to be, and he claimed that the process was far more accurate than the process of weighing and re-precipitation and so on, which was given in the paper. He noticed an average loss of about 5 per cent. by the reconversion. He should take it that that 5 per cent. of loss represented something more than alkaloid, and therefore he concluded that the substance was some impurity. He trusted that his criticisms would be well received, as they were given in the best spirit and with the simple object of evolving the truth.

Mr. Tanner asked why the authors chose a mixture of chloroform and alcohol as a solvent for the alkaloids of belladonna root. It seemed to him that chloroform *per se* would not dissolve the alkaloidal salts. He thought that it was pretty well recognized that the state in which the alkaloid existed was one of combination with organic acid. Therefore he was unable to see the object of employing chloroform. That body was a very good solvent for most alkaloids when uncombined, but it was contrary to his experience that it was a solvent of alkaloidal salts. The solvent action in the process appeared to have been produced entirely by the alcohol.

Mr. Dunstan, in reply, referring first to the remarks made by Mr. Luff, said that, of course, the use of iodine and potassium iodide did not absolutely ensure against an alteration of the alkaloid. The alkaloid might have been altered, but, on the other hand, it was extremely improbable in the present case that an alteration had taken place; and before they assumed that such alteration did actually occur some experimental evidence must be adduced. The evidence which was possessed at the present time was against any such assumption. A strong evidence in support of the non-decomposition of the alkaloid was found in the fact that the crystalline form of the residue at the end of the process was the same as the crystalline form of the pure alkaloid taken at first. If the resulting alkaloid was a different one, it would probably have some crystalline form different from the original one. Again, it was very improbable that any alkaloid would be altered, and especially that it would be saponified, without an alteration of weight. Mr. Gerrard admitted that the use of alcohol alone extracted more colouring matter than a mixture of chloroform and alcohol, and that was one reason why alcohol only had not been used in the process described in the paper. The extraction of the greater quantity of colouring matter involved difficulties later on. Mr. Gerrard's method seemed to be an extremely long one, and involved several processes of purification and repurification, and that appeared to be due to the fact that alcohol alone was employed as an extractive agent.

Mr. GERRARD said that the steps of his process were much shorter than those of Mr. Dunstan's process.

Mr. DUNSTAN said that surely nothing could be simpler than extracting the belladonna root with a mixture of alcohol and chloroform, shaking the mixture with water and then extracting the pure alkaloid with chloroform after the addition of ammonia. He did not deny that Mr. Gerrard's process was one of value, but it seemed to him that the process described in the paper was much shorter, and recommended itself by the fact that less colouring matter was extracted than when alcohol was used alone, and that the pure alkaloids were actually isolated and weighed, not inferred from the titration of an impure residue with an acid. That was really the point at the bottom of the paper. Mr. Gerrard, in further criticizing the process in detail, had said that the aqueous solution, which was obtained after shaking the chloroform-alcohol mixture with water, was coloured, and that the colour was not got rid of on agitating with chloroform. He (Mr. Dunstan) admitted that, but when ammonia was added, and subsequently the chloroform, it was found that the whole of the colouring matter remained in the ammoniacal solution and the chloroform separated practically colourless. Upon the spontaneous evaporation of that solution the alkaloids were got in a crystalline condition. Mr. Gerrard had gone on to criticize the results of the estimation of the pure alkaloids in the residues. As a chemist, Mr. Gerrard must know that it was impossible to get results within a milligramme, and it was obviously unfair to convert the numbers into percentages. The differences were only experimental errors, and the fact that a process of precipitation had been gone through must be taken into consideration. Mr. Tanner had referred to the solubility of alkaloids and alkaloidal salts in chloroform. No general rule could be laid down upon that point. In the case of the nux vomica, the alkaloidal salts could be extracted by chloroform alone, provided sufficient chloroform was used. In the case of belladonna the same result could be obtained, as the alkaloidal salts were also soluble in chloroform. This was referred to in the paper in connection with the first experiments.

The PRESIDENT said that this paper furnished another evidence of good work, and, he might say, of a great deal of work. It contained the result of a very long series of investigations. He could not but feel that a very large amount of experimental proof must have preceded the production of the paper. He had been very much struck by the observation of Mr. Luff with regard to the probable changes and the saponification of the alkaloid by the alcohol. He supposed that it must be admitted that the experiment which Mr. Luff tried upon himself was a fairly strong one. No doubt the point would be noticed by Mr. Dunstan in his further inquiries.

The last paper read was—

A NOTE ON A CASE OF SOPHISTICATION OF AMERICAN OIL OF TURPENTINE.

BY BOVERTON REDWOOD, F.I.C., F.C.S.

This paper is printed on page 665.

Mr. DUNSTAN said that Professor Redwood placed some of the residue in his hands on the previous morning, that he might find out its nature. In a rough experiment which he made he found that on treatment with solvents it yielded a substance which from its physical properties appeared to be pimaric acid. That acid was, he believed, yielded by two species of pines, namely, *Pinus pinaster* and *Pinus maritima*; and he believed that both those trees were found in South Carolina, where turpentine was produced. The quantity of residue which he had to work with was too small to enable him to speak very definitely.

Mr. DUNSTAN also called attention to the Government flashing point apparatus, which was on the table.

Mr. HOLMES, calling attention to various botanical and other specimens exhibited on the table, said that the samples of cinchona bark and the very fine selections of cinchonas had been recently presented by the Government. They came from the Darjeeling plantations, and represented the remainder that were not sent on the former occasion. The Society now possessed a tolerably complete set of the plants which yielded India barks and also of the barks themselves. There were also specimens of the solid and liquid paraffins, which had been recently introduced into the German Pharmacopœia. These were well worthy of attention.

The next meeting was announced for March 5.

Parliamentary and Law Proceedings.

THE SALE OF POISONS.—PROCEEDINGS AGAINST CHEMISTS AND DRUGGISTS.

At the Worcester City Police Court, on Tuesday, Mr. Edward John Kitson, chemist and druggist, Broad Street, was summoned, on adjournment, for selling poison contrary to the provisions of the Pharmacy Act, on December 19. Mr. Quarrell appeared for the defence.

Mr. Power, chief of police, stated that on January 22 last the case came before the Court, and he was then asked by Mr. Quarrell to produce a certain Order in Council which Mr. Quarrell alleged was published in the *Gazette* in 1869. He was now prepared to proceed with the case. There was no desire on the part of the prosecution to proceed against Mr. Kitson, but the only object was the safety of the public.

Richard Eadon, waiter, repeated his evidence as to the purchase of the poison, the subject of the summons. He went to Mr. Kitson's shop on the day named and obtained two pennyworth of chloride of lime and a packet of "rat killer." Witness was not asked to sign a book.

Cross-examined: Witness did not ask for poison but "rat killer." The packet was labelled "poison."

William George, a porter, who, it will be recollected, was tried for attempting to commit suicide by taking poison, deposed that he asked the last witness to fetch some mice poison for him. He did not say what he wanted it for. He admitted having taken the contents of the packet. He afterwards suffered from "pains all down the spine." He did not closely observe the packet. He remembered that it was labelled poison.

Police-Constable James spoke to going to the house of the last witness, finding him very ill, and restoring him by means of an emetic.

Dr. Swete stated that he analysed a small quantity of the rat killer remaining, which was brought to him in a bottle. He found it to contain strychnine.

Cross-examined: There was only a small quantity of strychnine.

Mr. Power produced a copy of the *London Gazette* for December 29, 1869, including preparations of strychnine as "poison" under the Act.

For the defence Mr. Quarrell submitted that the poison alleged to have been improperly sold, being a compound, and not a preparation, was exempt from the Act, and that the day before the alleged offence was committed, the defendant gave strict orders to his assistants not to sell any poison without duly registering it. A register of sales commenced on the previous day and continued ever since contained no register of the sale of rat killer on December 19, and no rat killer was sold on that day to any person answering to the description of Eaden.

Ernest Turner, one of the defendant's assistants, gave evidence bearing out this defence.

Being permitted to make a statement to the Bench, Mr. Kitson denied that rat poison was sold during his presence either on the 18th, 19th, or on any subsequent day in December, or up to the present time, without registration. He had given strict instructions to his assistants not to sell "rat killer" or any other poison without registering it, and he believed they had honestly carried them out.

Inspector Sommers said that on the morning Mr. Kitson came to the office of the chief of police and demanded the name of their informant in the first prosecution against him. He said he believed it was one of his assistants, and he had discharged that young man. Witness informed him that the police received information by letter. It was not written by any one connected with his establishment.

The Mayor said this prosecution had been instituted on public grounds. There was no desire to deal harshly with Mr. Kitson, as the magistrates had always known him as a respectable citizen.

A fine of 10*s.* 6*d.* and costs, £1 11*s.* 6*d.*, was inflicted.

At the Worcester City Police Court, on Tuesday, William Morris, chemist and druggist, was summoned for that on January 21 last, he unlawfully sold some prussic acid, being a poison named in the first part of Schedule A in the Pharmacy Act, 1868, to Eliza Ross, who was then a person unknown to him, not being introduced by some person known to him.

The Chief of Police (Mr. Power) said this was a somewhat peculiar case, for the purchase of the poison could not be proved, because the person who purchased it poisoned with it herself and her child. For the purpose of proving the case, however, he had given notice to the defendant to produce his register of the sales of poisons. There was no doubt an entry of the sale was made at the time, but he contended that it had not been made in compliance with the Act, the proper safeguards not having been taken.

Inspector Sommers stated that on the evening of the 22nd ult., he went to defendant's shop, and asked him to produce his poison register. Witness found in it an entry of the sale of sixpennyworth of prussic acid on the 21st to "Mrs. Jones, Carden Street." In reply to questions the defendant said he knew the woman well, that she was a charwoman, and had been a frequent customer at his shop.

In answer to the Bench, the defendant denied having described the purchaser as a charwoman.

William Ross, husband of the deceased woman, said his late wife never acted as a charwoman or went by the name of "Mrs. Jones."

Mr. Power deposed that, at the inquest held by the City Coroner on the bodies of the woman and the child, Mr. Morris said, in reply to the Coroner, that he had no doubt the deceased was the same person who made the purchase in question at his shop.

William Ross, being recalled and shown the entry in the defendant's register, denied that it was in the handwriting of his wife.

Mr. Power remarked that the defendant acted illegally in not acquiring sufficient information about the woman to conform with the terms of the Act.

In defence, Mr. Morris explained that he had known the deceased as a frequent customer at his shop for twelve months, and that he had often sold her quantities of laudanum which she had never improperly used, and he therefore contended that he had sufficient knowledge of her within the meaning of the Act.

A fine of £1 1*s.* and 13*s.* costs was imposed.—*Worcester Daily Times.*

Poisoning by Prussic Acid.

On Tuesday, February 5, an inquest was held at Norwich touching the death of Mr. F. W. Skipper, who had been found dead in his bedroom.

Mr. F. Bailey, surgeon, deposed to making a *post-mortem* examination of the body, and to deceased having died from taking prussic acid. Deceased had been in a low state of mind for some time past. The prussic acid produced was of Scheele's strength. Witness saw deceased on Saturday night, and from the appearance of the body when he made the *post-mortem* examination he thought he had been dead about sixteen hours. Witness believed deceased was at his club on Sunday night until ten o'clock.

Mr. Octavius Corder, pharmaceutical chemist, said the bottle he now produced was brought to him by Mr. Morse, who had found it on the washstand in deceased's room. There was now remaining in the bottle about forty drops of acid, which was quite sufficient to kill two adults. It was unusual to sell such a poison to any person, unless to a medical man. There was no seller's name on the bottle, and there was no mark upon it that could afford him any clue as to who sold the poison. The leather tied over the stopper of the bottle was an old piece of binding, and not like the leather placed on the bottle by a chemist. In his opinion the bottle was not sold by a chemist.

The Coroner said they had no need to go into the question as to where the bottle came from, even if he had information about it, but if it was ever found out who sold it, he should think it a proper case for the magistrates to deal with. He should send his notes of the inquiry to the Secretary of the Pharmaceutical Society, in London, whom he had always found ready to assist him.

The Jury returned a verdict "That deceased met his death by taking prussic acid, whilst in an unsound state of mind."

Decision under the Dental Act.

At West Ham, on Wednesday, February 6, the case of "Canton v. Holford" came before Mr. Phillips for judgment, in which Thomas Constantine Holford, a chemist and dentist, practising at 342-4, High Street, Stratford, was summoned by Frederick Canton, the hon. secretary of the British Dental Association, for having on November 14 last used the initials "L.D.S.," being the distinction of a qualification or certificate in relation to dentistry or dental surgery, which he did not possess, contrary to section 4 of the Dental Act, 1878, 41 and 42 Vic., cap. 33. The case is of some importance to the medical profeseion generally, as it is the first action decided under the Dental Act of 1878, which was framed on the lines of the old Medical Act of 1858, the 40th section of which corresponded with the 4th section of the Dental Act, under which these proceedings were taken, the *maximum* penalty imposable being £20. On the 25th of November, 1878, the defendant applied to Mr. William John Clark Miller, the registrar of the General Council of Medical Education and Registration, for registration under Clause A of the 6th section of the Dental Act, he signing himself "L.D.S., Ont.," but registration was refused. On April 15 following defendant applied for registration as having been in practice before July 24, 1878, and was registered under Clause C of the 6th section of the Act. Fraud was not alleged by the prosecution, who admitted that the defendant was a licentiate of dental surgery of the Medical College, Ontario, but they contended that by the use of the simple "L.D.S.," without the affix "Ont.," or "Ontario," Mr. Holford had made himself amenable to the Act. Mr. Phillips gave judgment at great length. Having reviewed the circumstances of the case, he said he had come to the conclusion that the title "L.D.S." simply was one which would only be granted by the medical authorities in this country, and that the defendant therefore had committed an offence within the meaning of the Act in using the designation of a qualification which he did not possess. He thought the defendant would have been within his right if he had used the letters "L.D.S., Ontario," but having omitted the addition, he had committed an offence. Taking into account, however, that this was the first case under the Act, and having regard to the fact that defendant was an "L.D.S.," though of Ontario, he should not impose the full penalty of £20, but a fine of £2, and the usual costs.—*Times.*

Correspondence.

The Examination of Chemicals.

Sir,—I shall be much obliged if you will allow me space to reply to Mr. Nicholson's remarks upon the above subject.

Liquor Potassæ.—Mr. Nicholson's calculation is quite correct, "20 ounces of pot. bicarb. would require 14·8 ounces of slaked lime to combine with the whole of the carbonic acid," but he seems to have overlooked the fact, that, when solution of potassium bicarbonate is boiled, carbonic acid is evolved. I find that under the circumstances named by me over one-fourth is so driven off. The remainder requires about 11 ounces of calcium hydrate. I used freshly slaked lime prepared from marble; still 12 ounces leaves but a small margin for the possible deterioration of the lime, etc.; the substitution of sixteen for twelve would give a better working formula.

The quantities mentioned did not apply to the cold process. I have lately made some in this way, using equal quantities of slaked lime and potassium bicarbonate. I found, however, that to complete the process, with such occasional agitation as I gave, required six weeks. With frequent systematic shaking much time might be saved.

Should the official formula for liquor potassæ at any time be altered, I hope the strength will be 5·6 per cent. KHO; as pharmacists would then have the usual volumetric solution always at hand, and the alteration could scarcely influence the present dose, etc.

Peroxide of Hydrogen.—Although this compound in strong solutions is very unstable, I am not by any means sure that a 3 per cent. or 10-volume solution is so much so as Mr. Nicholson's remarks would lead us to expect. Perhaps his paper (the publication of which is unfortunately delayed until next month) may contain some evidence on this point.

The test I used was that mentioned by Mr. A. H. Mason (*Pharm. Journ.*, [3], vol. xi., p. 705). He thus describes it: "A given volume is taken, and placed in a tube with excess of potassic bichromate. On agitation over mercury a volume of oxygen is evolved, which, supposing 1 c.c. of H_2O_2 has been taken, expresses its strength in so many volumes. Thus 1 c.c. of a 10-volume solution would yield 10 c.c. of oxygen at 0° C. and 760 mm."

To me this test offers the great advantage of being independent of any unstable reagent. But where a large number of samples have to be examined titration by means of potassium permanganate is undoubtedly more convenient.

I was rather surprised by Mr. Nicholson's statement as to "the volume strengths being properly only half of what" I stated; inasmuch as the bichromate was to all appearance unaltered and was capable of decomposing a further quantity of peroxide. The reaction differs according as the bichromate or the peroxide is in excess, but when 5 c.c. of a 3 per cent. or 10-volume solution of peroxide is mixed with 15 c.c. of volumetric solution of bichromate a brown coloration ensues; this disappears, more or less rapidly, according to the temperature, oxygen being evolved and the bichromate assuming its normal condition.

The following facts will, I think, disprove Mr. Nicholson's statement that "half of the oxygen liberated is due to the bichromate." A solution of bichromate was carefully standardized so that it should completely oxidize an equal volume of an acid solution of ferrous sulphate (the burette and reservoir containing this latter solution were supplied with an atmosphere of hydrogen). To 15 c.c. of the bichromate solution, 5 c.c. of solution of peroxide was added. When the reaction was complete, the solution was gently warmed, to free from dissolved oxygen, and the ferrous solution slowly added; 15 c.c. was required before potassium ferridcyanide indicated any trace of a ferrous salt in a drop of the mixed solutions. To another 15 c.c. of bichromate six separate lots (5 c.c. each) of peroxide were added, allowing sufficient time to elapse before each addition; the bichromate required 14·7 c.c. ferrous solution. As this experiment had been conducted in an open vessel, I thought that perhaps the deficient bichromate had been carried away mechanically during effervescence; the experiment was therefore repeated in a loosely covered flask with 10 c.c. bichromate solution, and five lots (in all 25 c.c.) of peroxide; 9·8 c.c. of ferrous solution was required. Finally, the two solutions were again titrated and found to be unaltered.

Of course where an acid solution of potassium bichromate is employed the reaction is different.

Citrate of Magnesia.—Mr. Nicholson's remark on soda water, that "it is well for the general consumer" it is not what its name would imply, refers equally to this preparation. Should Mr. Nicholson, for a moment forgetful of his chemistry, apply to a pharmacist for citrate of magnesia and be supplied with an article rightly so-called, he would probably find that, however much more worthy it was of its name, it was not so pleasant in use as our old friend "known to the public as citrate of magnesia," or "citrate of magnesia so-called," as it is frequently labelled. As to its further composition Mr. Nicholson's assumption is correct.

Liq. Sodæ Effervescens.—That manufacturers should be asked to make, and pharmacists to keep in stock, four preparations, where they now have one, I do not consider a practical suggestion. Better far to have the plain aerated water and to send out when requested suitable doses of sodium bicarbonate. Mr. Nicholson misreads me as to the quantity of chalk present in town water. I reckoned it in terms of sodium bicarbonate, $NaHCO_3$, and not as sodium carbonate Na_2C,O_3 as he states. By town water I meant London water, and under "liq. potassæ effervescens" so called it. The result arrived at was from my own experiments; observations, extending over many years, show that the variations have been very slight. I think from the large range (0·1 to 1·5 Na_2CO_3) Mr. Nicholson gives, he must refer in some cases to water supplied to provincial towns. As 1·5 grains $NaHCO_3$ equals 0·95 grain Na_2CO_3 the sample referred to by me would be well within Mr. Nicholson's experience.

NARCOTINE AND ITS DERIVATIVES.*

BY D. B. DOTT.

Narcotine was discovered in 1803 or 1804, by Derosne, but it was supposed to be a salt until its basic nature was demonstrated by Robiquet, in 1807. Narcotine exists in abundance in all kinds of opium; indeed, it is the only alkaloid besides morphia which opium yields in large quantity. Unlike morphia, however, it is a feeble base, not decomposing solution of chloride of ammonium when warmed therewith. Narcotine is interesting on account of the variety of compounds which have been prepared from it, and because of the light which has been thereby thrown on its constitution. The true composition of narcotine was not known until Matthiessen and Foster, as the result of numerous analyses, gave the formula $C_{22}H_{23}NO_7$, which has since been confirmed by Hesse. There is no proof that narcotine possesses a phenolic function, in respect of combining with alkalies like many other alkaloids, unless its ready solubility in alcoholic potash be evidence to that effect.

There is some difficulty in systematically arranging the different decompositions of narcotine, but probably the homologous series—

Trimethyl-nornarcotine	$C_{22}H_{23}NO_7$
Dimethyl-nornarcotine	$C_{21}H_{21}NO_7$
Methyl-nornarcotine	$C_{20}H_{19}NO_7$
Nornarcotine	$C_{19}H_{17}NO_7$

is most naturally first considered. The first member is ordinary narcotine. The second and third are formed by the action of hydrochloric acid, which eliminates first one and then another methyl radical as chloride, while the nornarcotine is only produced by the action of fuming hydriodic acid. The reaction cannot be carried further.

It is by oxidation that most of the derivatives of narcotine are formed. The oxidation is best effected by the action of manganese dioxide and sulphuric acid.

$$\underset{\text{Narcotine.}}{C_{22}H_{23}NO_7} + O = \underset{\text{Opianic acid.}}{C_{10}H_{10}O_5} + \underset{\text{Cotarnine.}}{C_{12}H_{13}NO_3}.$$

Matthiessen and Foster found that narcotine heated above 200° C. *per se*, or for a longer time in contact with water, splits up into meconin and cotarnine; and gave the equation—

$$\underset{\text{Narcotine.}}{C_{22}H_{23}NO_7} = \underset{\text{Meconin.}}{C_{10}H_{10}O_4} + \underset{\text{Cotarnine.}}{C_{12}H_{13}NO_3}.$$

Hesse, however, found that by the action of baryta water on narcotine hydrocotarnine is formed:—

$$C_{22}H_{23}NO_7 + H_2O = \underset{\text{Hydrocotarnine.}}{C_{12}H_{15}NO_3} + \underset{\text{Opianic acid.}}{C_{10}H_{10}O_5}.$$

He therefore inferred that narcotine is decomposed by water in the same way, and not according to Matthiesson and Foster's equation. As hydrocotarnine has since been found among the products of the action of water upon narcotine, it has been admitted that Hesse's reaction is probably correct.

$$C_{22}H_{23}NO_7 + H_2O = C_{10}H_{10}O_5 + C_{12}H_{15}NO_3, \text{ and}$$
$$C_{10}H_{10}O_5 + C_{12}H_{15}NO_3 = C_{10}H_{10}O_4 + C_{12}H_{13}NO_3 + H_2O.$$

Hydrocotarnine ($C_{12}H_{15}NO_3$) was obtained from opium liquors by Hesse, who has so greatly enriched our knowledge of the educts of opium. It is found in very small amount, but may easily be prepared artificially by the action of nascent hydrogen on cotarnine. Hydrocotarnine is a monacid base, melting at 55° C. By ferric chloride and other oxidizers it is converted into cotarnine.

Cotarnine, when crystallized from benzene, has the composition $C_{12}H_{13}NO_3 . H_2O$, the molecule of water not being separable without simultaneous decomposition of the base. The platinochloride may, however, be obtained anhydrous, by exposure for a sufficient time over sulphuric acid. By the action of dilute nitric acid cotarnine is converted into cotarnic acid:—

$$\underset{\text{Cotarnine.}}{C_{12}H_{13}NO_3} + HNO_3 + H_2O = \underset{\text{Cotarnic acid.}}{C_{11}H_{12}O_5} + \underset{\text{Methylamine nitrate.}}{N(NCH_6)O_3}.$$

Among the products of the oxidation of cotarnine is *apophyllic acid* ($C_8H_7NO_4$), discovered by Wöhler. It is a monobasic acid, with m.p. 205° C., but has been little investigated.

Both cotarnine and hydrocotarnine yield substitution products with bromine. When bromocotarnine hydrobromide is heated above 200° it melts, gives off hydrogen bromide and methyl bromide, forming the base tarconine, $C_{11}H_9NO_3$. Jörgenson, however, had previously described a base, homologous with that of Wright, which he called "tarconine." By treating an alcoholic solution of narcotine hydrochloride with iodine, Jörgenson obtained what he calls narcotine tri-iodide, $C_{22}H_{23}NO_7 . HI_3$. When boiled with alcohol the compound is said to undergo a "remarkable alteration," the tri-iodide of a new base being formed, *i.e.*, "tarconine," which has the composition of cotarnine less two atoms of hydrogen. The following equation is Jörgensen's:—

$$3(C_{22}H_{23}NO_7.HI_3) + H_2O = C_{12}H_{11}NO_3.HI_3 + C_{10}H_{10}O_5 + 4HI + 2(C_{22}H_{23}NO_7,HI).$$

Dr. Wright informs me that he was not acquainted with Jörgensen's paper when his own was written in 1877; otherwise he would not have adopted the name "tarconine." We are of opinion that Jörgensen's conclusions require confirmation. If correct, his base will, probably, require to be renamed "methyl-tarconine."

E. v. Gerichten has recently confirmed the accuracy of Wright's formula for tarconine, and has obtained several new bases from the bromo compound of that alkaloid. The principal bases are—*Nartine* ($C_{20}H_{16}N_2O_6$), formed by heating bromotarconine in a sealed tube with hydrochloric acid; *capronine* ($C_{21}H_{18}N_2O_6$) and *tarnine* ($C_{10}H_9NO_3$) are produced when bromotarconine is heated with water to 150°–160° C. Both nartine and tarnine yield pyridine by appropriate treatment. We know nothing of the constitution of cotarnine, except that it contains this pyridine nucleus and a methyl residue.

Opianic acid ($C_{10}H_{10}O_5$) is, undoubtedly, the most important of the narcotine derivatives. It is obtained in delicate white crystals. It forms salts, having the general formula $C_{10}H_9M'O_5$, the acid being monobasic. The action of hydrochloric and hydriodic acids is similar to that on narcotine, methylnoropianic acid and noropianic acid being produced. When opianic acid is heated with excess of strong solution of potash, meconin and hemipinic acid result.

$$\underset{\text{Opianic acid.}}{2C_{10}H_{10}O_5} = \underset{\text{Meconin.}}{C_{10}H_{10}O_4} + \underset{\text{Hemipinic acid.}}{C_{10}H_{10}O_6}.$$

* Abstract of a paper read before the Edinburgh University Chemical Society, January 9, 1884.

Under the influence of nascent hydrogen, opianic acid is reduced to meconin—

$$C_{10}H_{10}O_5 + H_2 = H_2O + C_{10}H_{10}O_4.$$

When heated with bichromate and dilute sulphuric acid, it is oxidized to hemipinic acid—

$$2\,C_{10}H_{10}O_5 + O_2 = 2\,C_{10}H_{10}O_6.$$

By the action of soda-lime on sodium opianate, *methylvanillin* is formed, which, when boiled with hydrochloric acid, yields vanillin, identical with that obtained from the pods of *Vanilla planifolia.* These important reactions are indicated by the following equations:—

$$C_{10}H_{10}O_5 = CO_2 + C_9H_{10}O_3, \text{ and}$$
$$C_9H_{10}O_3 + HCl = CH_3Cl + C_8H_8O_3.$$

Meconin ($C_{10}H_{10}O_4$) appears to exist in opium, and is formed from opianic acid as above described. It crystallizes in brilliant prisms melting at 110° C. By treatment with hydriodic acid, one methyl radical is removed, but nor-meconin has not been prepared, which would require the replacement of two methyls. By fusion with potash protocatechuic acid is obtained.

Hemipinic acid ($C_{10}H_{10}O_6$) was discovered by Wöhler, in 1844. It crystallizes in rhombic prisms, melting at 180° C. It is a dibasic acid forming salts of the formula $C_{10}H_8M_2O_6$. When heated with potassium hydroxide and water to 220°, it is converted into protocatechuic acid, $C_6H_3(OH)_2COOH + H_2O$. Hence, hemipinic acid may be regarded as carboxylated dimethyl-protocatechuic acid.

These are the principal derivatives of narcotine, but there are many more of less importance which we have not mentioned. Their relation to one another is better seen from the following formulæ:—

$$C_6H_2\left\{\begin{array}{l} O\,.\,CH_3 \\ O\,.\,CH_3 \\ COH \\ CO\,.\,OH \end{array}\right. \qquad C_6H_2\left\{\begin{array}{l} O\,.\,CH_3 \\ O\,.\,CH_3 \\ CO\,.\,OH \\ CO\,.\,OH \end{array}\right. \qquad C_6H_2\left\{\begin{array}{l} O\,.\,CH_3 \\ O\,.\,CH_3 \\ \left.\begin{array}{l} CO \\ CH_2 \end{array}\right\rangle O \end{array}\right.$$

Opianic acid. Hemipinic acid. Meconin.

$$C_6H_3\left\{\begin{array}{l} OH \\ OH \\ CO\,.\,OH \end{array}\right. \qquad C_6H_3\left\{\begin{array}{l} O\,.\,CH_3 \\ OH \\ COH \end{array}\right. \qquad C_6H_3\left\{\begin{array}{l} O\,.\,CH_3 \\ O\,.\,CH_3 \\ COH \end{array}\right.$$

Protocatechuic acid. Vanillin. Methyl-vanillin.

It will be observed that methyl-vanillin is dimethyl-protocatechuic aldehyde. The fact that this compound is obtained from opianic acid, and protocatechuic acid from hemipinic acid, shows that the carboxyl group removed in each case occupies the same position in the benzene chain. Now Barth has shown that protocatechuic acid is 1 . 3 . 4 dihydroxybenzoic acid, whence we know the positions of the aldehyd and methoxyl groups of opianic acid; but it is not evident which position the carboxyl group occupies. Wegscheider has undertaken the solution of this problem, and is presumably still engaged on his researches. Until the question of the constitution of opianic acid is completely answered, as likewise that of the constitution of cotarnine, it will be impossible to fix the true formula of narcotine. Although much information has been gained by recent researches, we are not yet in possession of that knowledge without which a synthesis of the alkaloid is hopeless.

ABRAHAM MUNTING,*

Dutch Medico-Botanist,

DE VERA ANTIQUORUM HERBA BRITANNICA.

BY JOSEPH INCE.

This strange old Latin book, illustrated with many fine botanical engravings, is rare; and the excellence of the plates has caused the work to be much sought after by artists.

It will compete in wordiness of style, and tendency to digression with any similar production of a mediæval writer; but yet it contains no more than a pardonable allowance of self-congratulation.

The author is convinced that he has hit upon a discovery of importance; and he never fails to thank God as the revealer of secrets that it was permitted to him personally to solve the mystery which for so long had obscured the virtues of a marvellous plant, and hid them from the knowledge of mankind.

The copy which, through the kindness of Mr. W. Dunstan, I have had the pleasure of reading is adorned with the usual allegorical frontispiece dear to the collector of such art curiosities, and frequently abstracted; as well as by a fine portrait of Henricus Casimir, of Nassau, to whom, and to many other illustrious persons, the treatise is dedicated.

The author defends his dedication and reasons that it is by no means inappropriate; for not only have the great busied themselves about plants, but have honoured certain herbs and preparations by the bestowal of their family cognomen. Gentian was was so called after its discoverer, Gentius, king of Illyria; Mithridates, king of Pontus, christened the Mithridate; whilst other royal personages followed his example.

Women even, Cicero instances as having been concerned in botanical nomenclature; for did not Artemisia, wife of Mausolus, king of Caria, bequeath her own name to a well-known medicinal plant.

The Roman emperors were not unmindful of the study of herbs, or slow to recognize their remedial efficacy. Our Lord himself, while rejecting the title of Emperor or chief, was not unwilling to accept that of the Healer; and sent Luke, the beloved physician, to preach the gospel in Antioch. It cannot, therefore, be deemed idle compliment to inscribe a book, containing the history of a plant, to princes and potentates.

Having thus cleared himself from the charge of flattery, Munting proceeds to address the reader in curiously phrased Latin and to cite his authorities. Laudatory verses are printed *in extenso* ; and then he settles down to his task, and to the composition of his first chapter. "In which is treated of the wonderful power of God, of his ineffable goodness and clemency; of the excellence and weakness of man; of the name of Britannica, its signification, honour and justness; also of the vain boast of some claiming to have made its discovery."

Much learning is expended in quoting ancient

* De Vera Antiquorum Herba Britannica ejusdem efficacia contra Stomacaccen, seu Scelotyrben Frisiis et Batavis de Scheurbuyck Dissertatio Historico-Medica auctore

Abrahamo Muntingio
Groninga-Frisio
Medicinæ Doctore, atque in Patria Groningæ et Omlandiæ Academia Botanices Professore, Amstelodami, apud Hieronymum Sweerts. 1681.

Aloidarium. Historia. 1680.

authorities as to the exact plant to which the term Britannica may be ascribed; but at length, Galen and Dioscorides are cited, who declare that while the Britannica has astringent leaves, good for wounds and much resembling those of *Lapathum agreste*; yet this plant has distinctive characters and the leaves are darker and more dense. It might without rashness, be taken for a species of Lapathum; and might be supposed not to have Frisia (Friesland) as its sole habitat, but to be common in other places.

The author immediately attempts to clear up the doubt by an elaborate description of the whole family of Lapathi, and tell us what Pliny said about it. When the statements of Hippocrates, Dioscorides, Galen and others have been examined, it remains that *Herba Britannica* is a plant which differs from the long list of those enumerated. Various authorities are then adduced in proof of the discrepancy of opinion which exists upon the determination of the true plant. Paulus Ægineta states that it resembles both in shape and general appearance the *Rumex sylvestris*. Oribasius, that it has leaves like *Lapathum sylvestre*, but darker and more hairy. The stem is not large; the root is black; and that the plant has an astringent taste. A crowd of other testimony is brought forward, the names of the writers being now almost forgotten, to support the same view. Petrus Andreas Matthiolus, a great authority, declares that Britannica is neither Bistort nor Tormentilla. Moreover, it is not Cochearia. The knowledge of the plant was lost in the time of the Goths, but was again discovered in that of the Gauls. Its virtues are alexipharmic and antiscorbutic. Numerous formulæ for its medical exhibition are introduced, amongst which are a decoctum, simple and compound; a syrup, gargle, dentifrice, electuary, extract, plaster, ointment, and many other recipes based on the polypharmacy of the period.

Seeing then that *Britannica vera* may be confused with certain other plants, Munting proceeds to give botanical details concerning all those for which it may be mistaken, and concludes his treatise with a description of the method of preserving, training and propagating the whole series. Very beautiful illustrations accompany the text and add much to the artistic value of the book, though strict criticism would hardly defend so elaborate a digression.

Thus we have plates of *Rhabarbarum rotundifolium verum* et *Fimbriatum*, *Lapathum Chinense longifolium*, *L. sativum antiquorum*, *Britannica Americana*, *Lapathum hortense*, *L. vulgare*, *L. unctuosum*, *L. acutum*, *L. longifolium crispum*, *L. sanguineum*, *L. planum paludosum*, *L. vulgare minus*, etc. *Oxylapathum tuberosum Americanum*, *Acetosa vulgaris*, *Acetosa Hispanica maxima*, and others; engravings of which will interest the botanist and the designer.

The treatise on aloes is also profusely illustrated. Many others, writes Munting, have attempted to describe the plant which forms the subject of the treatise, but all without success, and he first was permitted to reveal its true nature for the benefit of others.

Its discovery is thus narrated. There is a Herb called by some *Barba sylvana*; by others. *Plantago aquatica*. A certain noble maiden informed him of marvellous cures effected by this plant. The symptoms of the maladies so treated and relieved seemed to point but to the use of one plant, which he knew by reputation but which he had never seen at home, namely, the *Britannica*. His hope was disappointed, for when one day in the month of June he had diligently examined the plant said to have been employed, he found that it differed in many respects from the object of his search, and was probably that mentioned. In the year of grace (*Salutis anno*) 1672, July the ninth, there was a rumour, not a false one, that the enemy was nearing his native town (Groningen) and he was quietly engaged in punting about the marshes seeking herbs. He observed one of a dark black colour; not unlike Lapathum in appearance, often indeed seen by him before, but not in its native place, with the seed and some remaining flowerets. Immediately he ordered his boat to be stopped at the margin of a ditch, and the plant as being quite new, to be most carefully taken up by the roots. Then he perceived that the root was very black, a point which he examined with great care. When well washed it retained nearly all its colour, and his fingers were stained with a certain blackness. It possessed a wonderful astringency, and hence he no longer doubted that he had discovered the "true and legitimate Britannica of the Ancient Frisians." When, however, a very short time after, he beheld the enemy coming nearer, and that the advanced cavalry were taking him as it were in the flank; in order that he should not fall into their hands, he hastened home, all the same taking with him various plants and adorning his hat with their leaves as a symbol of imminent victory.

"Thus as if splendid with trophies I entered safely into the city." The field in which the plant was found was partly waste, and partly cultivated. It was marshy, and the soil was black. The adjacent village was called Wester-Broek (p. 80).

Next follows a lengthy, and many winding discourse about the character of the earth, and the names applied to it by Latin authors. None but an antiquarian enthusiast would be content to extract the small residue of fact which lies buried under the author's interminable sentences; the reader will be pleased to find that the word *cespes* may rightly be considered to mean turf or bog-land (p. 110).

"In this soil therefore I beheld growing in the water, on a first view as it were common, and not certainly *Rumex sylvestris*; very like *Oxylapathum*, a plant such as I had never seen in all my peregrinations." This is Munting's summary of the description of the ancients.

Britannica is a herb which has roots, stems, leaves, flowers and all seeds, very like *Lapathum agreste*, except that the roots are black; the leaves more oblong; and the leaves more black: stem, not much larger; all the rest similar (*consona*) as I have said.

The whole plant in all its parts has not an ordinary astringent power, but a remarkable one, and with a certain wonderful and strong power of penetration; for astringent remedies put forth (exhibit) this power almost on the superficies, and by their very astringency hinder penetration, and block up ingress. These points are further elucidated and much enlarged; the etymology of the word is discussed, but it is allowed to be immaterial whether the plant be called Britannica, Brittannica or Britanhica. Not till nearly two hundred pages have been exhausted do we come to the author's opinion that the plant about which he wrote so much was

Britannica Antiquorum vera
sive
Lapathum longifolium nigrum palustre.

It is stated to be infallible in scurvy, maladies of the stomach, wounds and serpents' bites. It obviously was of use as a peg on which to hang much learned disquisition.

The reader would perhaps like to see a specimen of the author's style:—

"Hisce tamen auspiciis faventibus, diversis in locis tam palustribus quàm Frisii maritimis omne Plantarum genus sedulò perscrutari aggressus sum, nullumque planè inexcussum omisi, nullis quoque sumptibus, vel laboribus gravatus fui, verum omne studium, omnemque operam adhibui, ut hanc Britannicam Herbam in Lucem rursus revocarem. Quod si idem et alii quoque facerent, non suæ tantum, verum et aliorum mortalium vitæ consulerent, deque posteris præclarè mererentur, atque hinc præterea famam assequerentur æternam.

"Si quidem ejusmodi beneficium posteri cum laude auctoribus perpetuò acceptum referrent. Hoc tamen mihi si non licuit, id saltem quod potui omni studio, atque industriâ præstare conatus fui; juxta illud, quærite et invenietis, pulsate et aperietur vobis; Rursum, Vitulâ meâ nisi arassetis, non invenisseris. Nec falsò joculari jactatur adagio, Vaccæ lac dare non propter cornua, verum illas mulgendas esse. Scriptum enim est: Petite et dabitur vobis."—P. 79.

Students of the literature of the 17th century may read the description of the siege of Groningen (p. 135), but we may say with Munting: verum ut redeam, unde digressus fui, tempus me vocat.

We may conclude by giving the laudatory verses written by Theod. Uchteman in old French.

"A Monsieur Munting, Docteur et Professeur en l'Academie de Groninge et Omlande, de la Medicine (*sic*) et Botanique sur son livre de l'Herbe Britannique.

"O Medicin divin, Prince des Iardiniers
Que Febus te couronne avec ses cerds Lauriers.
Qui monstrés le premier par ta sage pratique
Quel soit l'echantillon de l'Herbe Britannique.
Par tant de siecles de tous scavants ignoré.
Pour ce labeur ton nom sera tousiours doré."

The curious use as well as absence of accents will be noticed. I have ventured to translate the lines, thus:—

Divine Physician, Prince of Gardeners! may
Apollo surely crown thee with his bay,
Whose wise research has first show to our ken
Herba Britannica's true specimen.
Ignored for ages by all savants olden
For this work shall thy name be always golden.

THE CRYSTALLIZATION OF PHOSPHORIC ACID.*

BY P. L. HUSKISSON.

The crystalline form of phosphoric acid was first noticed by Süersen, Steinacher and Stromeyer, who obtained it in well defined crystals by evaporating a solution of the acid until it had the exact composition of H_3PO_4, a result which was confirmed by Krämer in 1869.

Péligot, in a paper read before the Académie des Sciences in the year 1840, stated that fused metaphosphoric acid, left in a botttle several years, absorbed water and formed at the top transparent crystals of orthophosphoric acid, in the middle, a mother liquid of specific gravity 1·7, and at the bottom, opaque indistinct crystals of pyrophosphoric acid, resembling loaf sugar.

Quite recently, however, Mr. H. P. Cooper, in a paper read before the Pharmaceutical Conference, 1881, stated that he had been unable to start crystallization in a solution of phosphoric acid, even when concentrated to a specific gravity of 1·850, without the introduction of some foreign substance, and used crystals of sulphate of sodium for that purpose.

Having observed certain facts in connection with the crystallization of phosphoric acid, which seemed to point to a different conclusion, the following experiments were made upon the subject.

It ought perhaps here to be mentioned, that during the writer of 1880–81 several bottles of 1·750 acid phosphoric in my father's laboratory, suddenly and without any apparent cause, crystallized, and it was with these crystals that some of the following experiments were made.

Starting with one of these crystals, if it was dropped into an acid of specific gravity 1·750, it was observed that the moment it touched the liquid it began to grow and rapidly filled the flask, evolving at the same time a large amount of heat. The crystals thus formed were in prismatic plates, hard and transparent and at ordinary temperatures easily kept in that state, if enclosed in stoppered bottles.

Experiments were then made with phosphoric acid of different strengths, and an acid of specific gravity 1·750 was the highest and specific gravity, 1·660 the lowest, that could be crystallized at the ordinary temperature. The weaker acids ought at the time of crystallization, to be surrounded by water, as the heat evolved by the first few crystals forming is sufficient to redissolve them and prevent the formation of others. The shape of the crystals from the weak solutions is especially well defined; they are transparent and in prismatic needles.

Endeavours were then mode to start crystallization in an acid of specific gravity 1·750, with a number of other crystals, both of the same and other groups, but without success, the following crystals being used:—

Acetic acid glacial	Cadmium nitrate	Potassium iodide
Alum	Copper sulphate	Potassium nitrate
Ammonium nitrate	Iron sulphate	Potassiumsulphate
Ammonium oxalate	Lead nitrate	Red potassium chromate
Ammonium phosphate	Manganese sulphate	Silver nitrate
Arsenic acid	Mercurous nitrate	Sodium arseniate
Barium nitrate	Oxalic acid	Sodium phosphate
Borax	Phenol	Sodium sulphate
Boric acid	Potassium bromide	Tartaric acid
	Potassium chlorate	Zinc sulphate

It was then tried to crystallize some acid by concentration, evaporating carefully so as to prevent the formation of meta or pyrophosphoric acids; but although acid of the specific gravity 1·860 was obtained, no crystals appeared. Finally some acid of specific gravity 1·750 was evaporated for one hour, keeping it at 160° C. (320° F.), and the evaporation finished *in vacuo*, when some tabular transparent crystals were obtained, which as soon as they came in contact with the air changed their form and became opaque, giving out at the same time a large amount of heat. The different behaviour of this acid, in crystallizing *in vacuo* while stronger acids in the air refuse to do so, is due to the fact that the acid absor bs water very readily.

When these crystals are dropped into acid phosphoric of specific gravity 1·750 no action takes place, nor can crystallization be in any way induced at that strength; but at a gravity of 1·800 it will take place readily after a short time.

It is interesting to notice that if a crystal of the former acid be placed in some phosphoric acid of specific gravity 1·800, nothing results; but if a few drops of water be added so as to reduce the strength, crystallization immediately begins.

As the attempt to crystallize phosphoric acid of specific gravity 1·750 with sulphate of sodium failed, two samples of specific gravities 1·800 and 1·850 were prepared, and into each a crystal of sulphate of sodium was placed, well stirred and left for thirty-eight hours. At the end of

---

* Read at a meeting of the School of Pharmacy Students' Association, February 7.

this time both samples were carefully examined, but in neither had any crystals made their appearance.

The results of these experiments indicate—(1) That a solution of phosphoric acid cannot be crystallized by any means when the specific gravity is lower than 1·660 at ordinary atmospheric temperatures. (2) Solution of phosphoric acid of specific gravities 1·660 and upwards will not under ordinary conditions crystallize spontaneously or upon agitation. Neither can it be crystallized by the introduction of sodium sulphate or any other foreign crystal. When a crystal of orthophosphoric acid is introduced, crystallization at once commences. (3) Phosphoric acid having a specific gravity of 1·800 can be crystallized spontaneously by exposing over sulphuric acid *in vacuo*. The crystals then produced are unable to start crystallization in phosphoric acid of lower specific gravity than that from which they have been produced (1·800), and on the other hand the crystals obtained from weaker solutions are unable to induce crystallization in the stronger acid of specific gravity 1·800.

TRUFFLES.*

Among forgotten or forsaken industries in this country is that of gathering truffles. Truffle hunters and their dogs are alike extinct. In the last century, Gilbert White, of Selborne, living among beech woods, received a call in the month of August from a truffle hunter, who showed him several large truffles found that day. He gave some interesting information to the effect that truffles were not to be found in deep woods, but in narrow hedgerows and the skirts of coppices. In a thick beech wood the mass of roots so entirely occupies the ground, that nothing can grow. Sometimes, said the man, the truffles lie two feet under ground, sometimes at the surface, and those that lie deep, he affirmed, were more easily found by the dogs than the others, the shallow-lying ones having little or no smell. The price he asked for his truffles was half a crown a pound; they were in season in different situations nine months in the year, and were least abundant in wet winters and springs.

English truffles are now as much out of date as English wine, and for the same reason—the foreign growth is better, and is more easily obtained, as somewhat recent experiments in this country prove. Like the vine, they were found only in a few districts, requiring not only a warm situation, but a soil containing a considerable percentage of lime—2 or 3 per cent.; limestone soils therefore suited the truffle best. It is a parasitical plant living on the roots of trees. It is in fact a tuberaceous mushroom, which affects trees through the necessities of its growth, requiring, as it does, a large amount of phosphoric acid and of potash, which are supplied in the decay of the leaves annually shed from the trees. In England it is found among the beech woods of the chalk formation in Surrey, Sussex, Hants, and a few other districts, and thus it was erroneously supposed to affect beech trees only; but in France it is found on several limestone formations, and in connection with several sorts of trees, especially the chestnut, pine and oak. M. Chatin, a learned authority on the truffle and on agriculture, has published an exhaustive work on these vegetables from their germination to their appearance in a Perigord pie! Their growth, as a marketable crop, is exceedingly slow, and although the truffle harvest of France, reaped chiefly in a few districts of the South (though the truffle is found in fifty departments), yields 3,500,000 lbs. in weight, the growers receiving for it £400,000, and the retailers £1,000,000; still the crop is of Nature's planting and production, and it has not yet become a subject of cultivation. A good dog, or still better a sow, getting only a chestnut or acorn by way of wages for each find, will enable the hunter of the vegetable to bag 10 or 12 lbs. in one day in a good district, and these are worth £2 on the spot, and £4 or £5 in New York, London, Paris, or St. Petersburg. M. Chatin enlarges both on the dogs and pig, of Perigord. They are indispensable, and the latter are the most useful, being trained not merely to find the truffle but to uproot it and turn it out with their strong snouts, or lay it bare as their previous education may direct them. Dogs are chiefly used in Provence, and their obedience and acuteness are equal to that of the pigs, and their noses are almost as good, but they lack the faculty for uprooting the game. Each animal will scent the truffle from a considerable distance, lead the hunter to it, and stand to it, staunch as a pointer to a bird or hare, till the order is given to advance and take possession.

It is thought in France that truffle growing might be extended like fruit growing in England. Some say that ten times as many truffles might be grown. The difficulties, however, seem great. M. Chatin has not found the spores of this mushroom very manageable. The black truffle of Perigord ripens in October and remains in season through the winter. In the early spring it decomposes and the germs are set free and become mixed with the soil, ready for reproduction, after the manner of cryptogams of this class. White filaments are formed which accumulate into a mass, and from this mycelium the truffles grow, but, says M. Chatin, the tubers are incubated from this filamentous body only after a lapse of several years. The saying, "No trees, no truffles," indicates the position of their growth, and the experience of the Hampshire truffle hunter, that he found them on the borders of copses and hedgerows rather than in deep woods, indicates with accuracy some of the conditions of their growth. They require a light, dry soil, full of vegetable matter, and manured by the fall of leaves; but they are crowded out, like other vegetation, when the wood grows dense. Truffles accordingly are not found in young woods less than from six to ten years old, and the woods usually become too dense for them at thirty or forty years old. M. Chatin recommends the culture of the crop, and feels certain it would pay. He would plough the ground between the rows of young trees in a newly formed plantations, and plant the "tubers" in rows two yards apart, growing grain on the same ground for three or four years. In about six or eight years he would expect an abundant truffle harvest. Assisted by the pigs he would go on reaping a crop from year to year, till it might be necessary to begin upon the trees, thinning the timber for the sake of the truffles! We shall hope with M. Chatin that the supply of truffles may be increased tenfold, though undoubtedly the difficulties of cultivation are greater than in the case of mushrooms, for reasons which are obvious.

* From the *Gardeners' Chronicle*.

THE OPIUM TEST OF THE GERMAN PHARMACOPŒIA.*

The new edition of the German Pharmacopœia describes a method for the estimation of the morphia in opium and in three preparations made from it, and requires that the opium when thus assayed shall yield at least 10 per cent. of morphia. The object of a series of experiments, instituted by Dr. Geissler, was to ascertain to what extent the process was reliable.

The following are the details of the process prescribed by the German Pharmacopœia:—Eight grams of opium are mixed with 80 of water, frequently shaken during half a day (? twelve hours) and filtered; to 42·5 grams of the filtered liquid 12 grams of spirit, 10 of ether and 1 of liq. ammoniæ are added, the mixture is set aside in a cool place (10°–15° C.) and frequently agitated. After the lapse of twelve hours the precipitate is collected on a tared filter 8 centimetres in diameter, washed with a

* Abstract of a paper in the *Pharmaceutische Centralhalle*, 1883, Nos. 16 to 19.

mixture of dilute spirit, water and ether, in successive portions of 2 grams, and dried. It should weigh not less than 0·4 gram.

One part of the morphia thus precipitated dissolves completely in 100 parts of lime water, forming a yellow solution, which is coloured reddish brown by a little chlorine water and blue or green by solution of perchloride of iron.

The method is essentially the one devised by Prollius, and minutely described by Flückiger,* which has been criticized at length by Mylius† and van der Burg.‡

A sample of Turkey opium, guaranteed to contain 10 per cent. of morphia, was obtained from a drug house of high repute, and from it tincture and extract were prepared according to the pharmacopœial instructions.

The opium tested by the official method yielded 4·4 to 4·7 per cent. of morphia; the tincture, 5·2 to 6 2; the extract, 7·9 to 10·4 per cent. By allowing the mother-liquor to stand thirty-six hours longer these figures were increased to 7·7 to 8·1, 7·0 to 8·2 and 10·1 to 10·7 for opium, tincture and extract respectively. A second sample of opium, guaranteed to contain 10 per cent., yielded 8·0 to 8 3 per cent. in forty-eight hours; the tincture from the same gave 7·5 to 8·2 per cent. From a third sample of opium, however, as much as 13·7 to 14·1 per cent. were obtained. The time prescribed by the Pharmacopœia is, therefore, far too short; the amount, also, of morphia obtained from the tincture is larger than the percentage contained in the opium would lead one to expect.

Slight variations in temperature were found to be without appreciable influence on the result and constant agitation was also unsuccessfully tried.

Both Mylius and van der Burg have proved that a correction must be made to compensate for the morphia that remains dissolved in the mother-liquor; this correction is placed at 2·2 to 2·5 per cent. of alkaloid in the opium. If then the Pharmacopœia requires that 10 per cent. of morphia shall be obtained from the opium the quantity of alkaloid contained in the same must be 12 to 13 per cent.

A series of experiments was then undertaken to ascertain whether more morphia was retained in the mother-liquor of the official process than in that of other processes; and this was found to be the case.

The precipitated alkaloid was next tested with lime-water in which it should dissolve completely; this it failed to do, and a closer examination showed that the morphia precipitated by the German official process from infusion of opium contained varying amounts (15 to 18 per cent.) of narcotin; that precipitated from the tincture contained still more, hence the apparent excess of morphia in the latter, to which attention has already been directed. The narcotin was estimated by treating a weighed quantity of the powdered precipitate with *pure* chloroform, drying and weighing.

The author sums up his results as follows:--

The method of the German Pharmacopœia does not separate the morphia completely.

The morphia separated is at least not always pure.

The results are not uniform.

These objections may be urged against every method of estimating morphia that has yet been proposed, but the process of the Pharmacopœa Germanica leaves more in solution than others do and yields a less pure morphia. To comply with its requirements an opium must contain 12 to 13 per cent. of morphia.

In his concluding remarks Dr. Geissler expresses his approval of Mylius's volumetric estimation of morphia,§ but hopes soon to perfect a gravimetric method based upon the solubility of morphia in ammonia.

LUFFA ÆGYPTIACA.*

BY REINHARD J. WEBER, PH.G.

Description.—*Luffa œgyptiaca*, nat. ord. *Cucurbitaceœ*, is indigenous to Egypt and Arabia, and is a large climbing vine, with a thin, but very tough, light green succulent stem, attaining a length of from ten to thirty feet. The leaves are alternate and palmately lobed, of a light green colour and almost destitute of taste. The flowers are monœcious; petals five, united below into a bell-shaped corolla; anthers cohering in a mass; ovary two-celled, style slender, stigmas three. The fruit is elliptical ovate, fleshy and indehiscent, with a green epidermis, longitudinally marked with black lines, varying from ten to fifteen it number; under each of these lines is found a tough woody fibre. The fruit attains a length of from six to twenty-five inches. I have seen a specimen of the fruit grown in Allentown, Pa. which measured thirty-four and a half inches in length, and nine inches in diameter. When the epidermis is removed it presents a layer of interwoven woody fibres, which may be used like a sponge, being hard and rough when dry, and soft when soaked in warm or cold water; they absorb the latter with the same facility as the ordinary sponge, and have the advantage over the sponge not to wear out by ordinary use for a number of years; hence, the name of "Vegetable Sponge," or "wash rag," and its use as a flesh glove. The seeds are numerous, and are almost flat, broadly ovate, three-eighths of an inch long. The testa is of a blackish brown colour and rough, cotyledons almost flat, of a yellowish brown colour and oily.

Analysis.—An infusion of the epidermis of the fruit (1 to 10) was made and tested for tannin, with tincture of chloride of iron, with sulphate of iron, and Russian isinglass, whereby a trace of tannin was shown. One hundred grains of the epidermis, thoroughly dried, yielded fifty-four per cent. of residue; on being incinerated at a low heat, the epidermis (dry?) yielded twelve per cent. of a dark grey ash, one half of which was soluble in water; the ash consisted of silica, carbonates and sulphates of potassium and calcium. The fibrous portion, after being incinerated, yielded sixteen per cent. of ash, partly soluble in water.

The fruit contains a large amount of mucilaginous substance, which yields a white precipitate with solution of subacetate of lead.

An infusion of the fibrous portion, when evaporated to a syrupy consistence, became gelatinous on cooling. The gelatinous mass had all the properties of bassorin, and was free from starch. One troy ounce of the epidermis was powdered, and successively exhausted with benzin, alcohol and water. The benzin solution yielded a small quantity of yellow colouring matter; the alcoholic tincture left chlorophyll and a little extractive, and the infusion gave twenty per cent. of slightly bitter extract.

One troy ounce of the powdered seeds was treated with boiling benzol; the green solution, on being evaporated, yielded two and a half per cent. of a brown, fatty oil, and twelve per cent. of a green mass. The latter, on being treated with very dilute hydrochloric acid, and evaporating the liquid, yielded a minute amount of crystals. Similar crystals were also obtained from the green alcoholic extract of the seeds previously exhausted with benzol. Water afterwards took up nothing of note.

Mode of preparing the fibrous portion.—The fruit is cut longitudinally on one side, stripped of the epidermis, the seeds are then removed, and the network of fibres is washed thoroughly to get rid of the mucilaginous substance and dried. It is then ready for use. This fibrous portion is the only part of the plant, as far as I know, that has ever been in use.

THE LAWS RELATING TO ARSENICAL PIGMENTS AND OTHER POISONOUS SUBSTANCES IN FOREIGN COUNTRIES.

ABOUT twelve months since, a Committee of the National Health Society, appointed for the purpose of considering the injuries arising to health from the use of arsenical and other poisonous pigments in the tinting of wall-papers and textile fabrics and for other industrial purposes, applied through its Chairman, Mr. ERNEST HART, to Earl GRANVILLE to instruct the agents of the Foreign Office at courts on the continent of Europe and in America to report on the legislation affecting this subject existing in other countries. In compliance with this request a circular was immediately afterwards issued from the Foreign Office giving the necessary instructions, and the consequent reports have just been issued in the shape of a paper presented to Parliament by command of Her Majesty. Besides the information relating to foreign legislation having for its object to restrict or safeguard the manufacture, use, or sale of arsenical and other poisonous pigments, which was the special object of the inquiry, there are scattered through the reports various incidental references to regulations affecting the sale of "poisonous substances" in different countries by persons other than pharmacists, which are of special interest at the present moment.

Turning, however, first to the special subject of the return, we find that reports have been received from British representatives at twenty-two different courts. Several of these reports may be at once eliminated from consideration as negative. Thus, in Belgium, France, Italy, Netherlands, Portugal, Servia, Spain, Switzerland and the United States, there are no special laws relating to the use of arsenical or other poisonous pigments. Respecting these countries nothing need be said at present except that in France a circular was sent out some years ago cautioning manufacturers as to the responsibilities incurred in using poisonous pigments, in Greece the use of poisonous colours in confectionery and liqueurs is prohibited, in Italy a law on the subject is being prepared, and in the Netherlands it is considered that the ground is practically covered by penal laws dealing with the selling of merchandize known to be dangerous without a special warning. The list may be further reduced by grouping Baden, Bavaria, Hesse-Darmstadt, Saxe-Coburg-Gotha, and Saxony together with Germany, since practically they are all regulated by an Imperial decree issued in 1882, which forbids the "use of colours containing arsenic for "the preparation of wall-papers, and of colours "containing copper and arsenic for dyeing stuffs for "clothing," and also the sale of articles of clothing dyed with these poisons. In Austria the employment of arsenical pigments for colouring wall-papers, artificial flowers, textile fabrics or papers is prohibited; also the employment of aniline or mineral colours in the manufacture of articles of consumption, or of mineral colours containing copper, arsenic, lead, or zinc in stuffs intended to come in contact with the human body, as well as the application of litharge or bad enamel to table and kitchen utensils. In Denmark the use of arsenical compounds for staining, dyeing or colouring, or preparations of lead for toilet articles, or oxide of zinc in india rubber ware is strictly forbidden. In Roumania there is no provision as to wall-papers, but the use for wrapping purposes of paper coloured with poisonous pigments is prohibited. Russia has stringent statutes against the importation, sale or manufacture of papers or textile fabrics coloured with arsenical pigments, or the importation of aniline colours otherwise than in crystals, or the use of "papier nacre," which is covered with an enamel containing lead. Lastly, Sweden is officially described by its State Board of Health as being just now under the influence of a "fashionable arsenical panic," the force of which may be estimated by the fact that the number of analyses for arsenic indulged in by the Swedish public reaches at least ten thousand annually. In that country, as in others, "different analysts arrive at different results," and, as one analyst, at least, is said to pronounce, without further examination, "every crystallization in the tube, even though it be scarcely perceptible, to be arsenic," it is not surprising that the panic is maintained and that regulations are enforced in a manner that sometimes proves very inconvenient to manufacturers and importers.

With respect to the second topic alluded to, the bearing of which upon the Draft Pharmacy Bill will be evident, it appears that the Hessian Police Code draws a distinction between "direct poisons," which can be legally sold only "apothecaries and druggists," and substances of a "poisonous nature," which may be sold under certain precautions to adults by any grocer holding a special police licence. The list of these "poisonous" articles includes the mineral acids, metallic pigments and certain vegetable substances "commonly used in art and industry." In Russia poisons are divided into four classes, one of them being described as "poisonous and violently acting substances employed in manufactures and not well adapted to criminal purposes." It appears that this class, which includes the mineral acids, oxalic acid, potassium cyanide, sugar of lead, arsenical and copper pigments, etc., may be sold in ordinary business transactions by "merchants of the two guilds," subject to certain conditions, amongst which are the holding of a licence and registry of sales; but at fairs the sale of these "poisonous and violently acting substances" is unrestricted. In Servia poisons and poisonous articles may be sold by "authorized merchants" only to persons who have received special permission from the police to purchase. In Sweden such "poisonous substances as are used for generally occurring technical or domestic purposes," provided certain conditions as to storage are complied with, may be sold by any person legally carrying on business who shall deliver to the authorities a written specification as to the poisonous substances he proposes to keep for sale. But it is worthy of note that the same substances may be sold by a pharmacist, only under much more stringent conditions. One more regulation, issued by the municipality of Bucharest, may be referred to rather for its oddity than its importance. The municipality, believing that cases of poisoning are often produced by the use of poisonous cosmetics, and having received frequent complaints that several hairdressers, perfumers, "and even chemists," of the capital have been selling cosmetics containing lead and mercury for the tinting of the face, and "seeing that several women of the capital make and sell the same poisonous cosmetics," forbids the sale within the limits of Bucharest of any cosmetics, or similar washes, pomades or powders, containing preparations of lead or mercury.

THE CHEMIST AND DRUGGIST IN JAPAN.

A Report upon taxation and land tenure might seem to be a most unpromising exploring ground for information relating to the practice of pharmacy or what most nearly represents it in a particular country; but, nevertheless, the reader of a Report on this subject by Mr. Gubbins, an *attaché* to the English Legation at Tokio, recently submitted to Earl Granville, may find imbedded in it, like a fly in amber, an interesting summary of the conditions under which drugs and medicinal preparations are supplied to the Japanese public. The particulars given correspond fairly well with the statement made in Isabella Bird's recent work 'Unbeaten Tracks in Japan'; but as in the Report they are somewhat more fully stated, and probably few of our readers will have an opportunity of consulting the book, we may be excused for transferring the gist of them to these columns.

According to Mr. Gubbins, the "profession of a druggist" in Japan does not coincide with that of a foreign "apothecary." This latter word, we presume, he uses in its pharmaceutical aspect; for he adds that before the country was open to foreigners, there was no such class, the sale of medicine having been confined to "doctors," who either supplied medicines prepared by themselves according to original recipes or according to prescriptions of others, or, perhaps more commonly, sold medicines already prepared and known to practitioners and patients by the names of "doctors" who compounded them. About the year 1877, apparently in consequence of the encroachment of foreign medical science upon native systems of medical treatment, the supply of medicines became the subject of legislative enactments, and for the purposes of taxation persons engaged in it were divided into three classes,—druggists, retail dealers and itinerant sellers of medicine. It would appear, however, that the members of one only of these three classes, the "druggists," enjoy the privilege of preparing medicines, though this is not made quite clear in the Report; at any rate they differ from those in the other classes in being more heavily taxed, and in paying their taxes into the national exchequer. The taxation is imposed in a form not calculated to encourage the multiplication of specialties, a tax of two yen yearly (about 7*s.* 6*d.*) being payable on each separate medicine prepared and sold by the druggist, besides which he must hold a licence to sell, renewable quinquennially, for which he pays a fee upon taking it out and renewal at the rate of 20 sen (about 9*d.*) for each medicine. The term "prepared medicines" is defined as comprising medicine in a liquid form, and in the form of pills, ointments and powders. The details of the composition, weight and taste of each separate medicine, of its alleged medicinal properties and of the dose have to be furnished to the Home Office at the time of making application for a licence to sell it; power being reserved to the Home Office to refuse a licence in the case of any medicine which might be considered dangerous. Even here the limit of taxation to which the Japanese "druggist" is liable is not reached, for he has to attach to all drugs sold a stamp representing 10 per cent. of their price, which is fixed by Government. The pettiness of this tax may be estimated from the fact that the first item of the regulation provides that on medicines of the price of 1 sen (less than a halfpenny) a stamp of 1 rin (about one-twentieth of a penny) shall be affixed. The penalties for breaches of these regulations range between 7*s.* 6*d.* and £3 15*s.*, the latter penalty being for the sale of unstamped medicines. In a recent report Mr. Consul Robertson made the remark that patent medicines, or drugs put up in a popular form, are greatly in vogue in Japan, and that a good many imported articles go into consumption in this shape. He also stated that an intimation that a tax would be imposed upon these remedies had already seriously affected the business, and was thought likely to operate still further to its disadvantage. The Japanese authorities, however, do not appear to share this anticipation, since the financial budget for the present year includes an estimated increase of revenue from this source amounting to

600,000 yen, or about £110,000. The tax paid by "apothecaries" and "medicine pedlars" is a local one, and is in the form of an annual licence for which the fee is £3 15*s*.

An Evening Meeting of the North British Branch of the Pharmaceutical Society will be held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday next, when the papers read will be on "The Composition of Potassæ Sulphas cum Sulphure," by Messrs. Maben and Deehan, and on "The Morphology and Physiology of the Cell," by Mr. Patrick Geddes. The chair will be taken at 8.30.

* * *

We learn from the New York *Pharmaceutische Rundschau* that a Bill has been introduced into the House of Representatives at Washington and ordered to be printed which would provide for the preparation of a legally authoritative National Pharmacopœia of the United States. It proposes that with this object the Finance Minister should appoint two officials of the United States Marine Hospitals, the War Minister two officials of the Military Medical Department, and the Minister of Marine two officials of the Naval Medical Department, in order to carry out the work, and that these officials should invite the American Medical Association and the American Pharmaceutical Association each at its next annual meeting to select three of its members to form a Committee to act jointly with them in preparation of such a work. The Joint Committee would be empowered to elect a President and a Secretary from its midst, and to supply any deficiency in its number by the election of new members. The printing and publishing of the official Pharmacopœia would be in the hands of the Committee and the work would have to be revised every ten years. The Bill also provides for a grant of five thousand dollars for payment of the expenses necessarily incurred in carrying out the measure.

* * *

The Registration of Firms Bill, referred to last week as having been read a first time in the House of Commons, has now been issued and proves to be similar to the Bills introduced in previous years. It provides that every firm carrying on business in the United Kingdom under a firm-name which does not consist of the full or the usual names of all the partners or all the acting partners without any addition, and every person carrying on business under a firm-name consisting of or containing any name or addition other than the full or usual name of that person, shall effect registration in a prescribed manner. The register, which is to be open to public inspection for a small fee, is to show the firm-name, the nature of the business, the place or places of business, and the full name, usual residence, and other occupation of any of the person or persons carrying on or intending to carry on the business. Upon any change occurring in the constitution of a firm the members of the firm as reconstituted would have to furnish information as to the change within a month; any change in the firm-name would involve fresh registration *de novo*. It will be evident that the existence of such an Act would in certain cases greatly facilitate the performance of the duties of the Registrar under the Pharmacy Act.

A Bill, introduced into the House of Commons by Mr. Kennard, having for its object to repeal such sections of any Act of Parliament as enable mixed traders, other than duly licensed victuallers, to deal in the retail sale of spirits and liqueurs, contains a provision that nothing in it shall affect or apply to —among other things—"the sale of medicated or methylated spirits, or spirits made up in medicines and sold by medical practitioners or chemists and druggists." The juxtaposition of the first two articles mentioned, and indeed the tenour of the whole clause, is suggestive of a very limited acquaintance on the part of those who drafted the Bill of the conditions under which either medicated or methylated spirit is sold.

* * *

As the esteemed editor of our medical contemporary, the *Lancet*, appears to be engaged in studying the proclivities of various journals, as indicated in the announcements made in their advertising pages, we hope he will not overlook one in the columns of his own journal for last week, in which a surgeon, enjoying the possession of commanding premises at the West-end, advertises "a fine opening for a chemist's business or *surgeon's retail*."

* * *

The commercial samples of liquid starch sugar, or "glucose," examined by the Committee appointed in the United States to investigate the subject, to which reference was made last week, were found to contain from 34·3 to 42·8 per cent. of dextrose, 0 to 19·3 per cent. of maltose, 29·8 to 45·3 per cent. of dextrin, and 14·2 to 22·6 per cent. of water. The samples in the solid form—"grape sugar"—ranged in composition from 72 to 73·4 per cent. of dextrose, 0 to 36 per cent. of maltose, 4·2 to 9·1 per cent. of dextrin, and 14 to 17·6 per cent. of water. Three specially prepared samples of "grape sugar" contained respectively 87·1, 93·2 and 99·4 per cent. of dextrose, the last being "crystalline anhydrous dextrose." The ash in the "glucoses" varied between 0·325 and 1 per cent., and in the "grape sugars" between 0·335 to 0·75 per cent. The reporters add that in the United States starch sugar is chiefly used in making table syrup and artificial honey, in brewing and vinegar making, as well as in the adulteration of cane sugar and as a substitute for it in confectionery and canning fruits. It is estimated by the Committee that the industry in the United States gives employment to twenty-nine factories, which together represent a capital of £1,000,000, consume about forty thousand bushels of maize daily, and produce "glucose" and "grape sugar" to the value annually of £2,000,000.

* * *

We are requested to state that in consequence of the great demand for tickets, the annual dinner of the Chemists' Assistants' Association, which takes place at the Holborn Restaurant on the 20th inst., will be held in the Venetian Room (Grand Entrance), and not in the Duke's Saloon as advertised.

* * *

At the next meeting of the Chemical Society, on Thursday, the 21st inst., there will be a ballot for the election of Fellows, and a paper will be read on "An Analysis of Spotley Bridge Spa Water," by Mr. H. Peile.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council was held on Wednesday, February 6; the President, Mr. James E. Brunker, M.A., in the chair.

Present:—Mr. H. N. Draper, Vice-President, and Messrs. Allen, John Evans, Grindley, Hayes, Hodgson, McIlwain, Dr. R. Montgomery, Dr. Aquilla Smith and Professor Tichborne.

The Registrar read the minutes of the last meeting, which were confirmed.

A letter was read from Dr. Kaye, Q.C., clerk to the Privy Council, enclosing an Order of Council confirming the resolution of December 5, 1883, relative to the time to be spent in learning practical pharmacy.

The President: The new regulation requiring four years to be spent in the learning of practical pharmacy came into force from January 1 last, and is now law.

A communication was received from the Attorney-General for Ireland, forwarding his replies to the following queries:—

"*Queries* submitted to counsel on behalf of the Council of the Pharmaceutical Society of Ireland:—

"The Council have been entrusted with the duty of administering the Pharmacy Act, Ireland (38 and 39 Vict. c. 57), and have been empowered to make regulations which, subject to the approval of the Lord Lieutenant and Privy Council (sec. 17) have the force of law. The Council have found difficulty in construing the legal interpretation of the term 'person keeping open shop,' how far it may extend, or how it may be limited (*vide* sec. 30).

"On this point counsel's opinion is sought. The following case now before the Council illustrates the difficulty. Candidates presenting themselves for the licence of the Society must produce certain certificates from a pharmaceutical chemist or apothecary keeping open shop (*vide* p. 55 of the Society's Calendar). A Mr. Hardy, a licentiate of the Society, seeks for recognition of his certificates under this regulation, but under the circumstances detailed below. A firm named Beater and Co., carrying on business at 17, Lower Sackville Street, as 'general druggists,' have entered into an arrangement with Mr. Hardy, who is one of the partners of that firm, under which he rents from the firm a portion of the premises in which the general drug business is carried on, as a compounding department. It appears that the profits of the compounding department are exclusively enjoyed by Mr. Hardy; but it also appears that the department is only a portion of the general business shop, and that there is a common entrance to both, the name on the door being 'Beater and Co.' The case in question is a comparatively unimportant one, but will govern others which may arise. Counsel will please advise—

"1. Whether the singular 'person' can be held to imply and include 'persons' under the Irish Pharmacy Act, or if there is any general interpreting Act in the Irish statutes affecting the point? Counsel's attention is directed to an English case, The Pharmaceutical Society of Great Britain *v.* the London Supply Association, 5 Q. B. D., p. 310, which was finally adjudicated on in the House of Lords. It is necessary to keep in mind that the Irish Act, though closely following the Pharmacy Act (Great Britain), 1868, is not, owing to antecedent circumstances, on all fours with it. In Great Britain any person before the passing of the Pharmacy Act could compound physicians' prescriptions; while in Ireland the right to compound prescriptions formerly enjoyed by apothecaries only is now extended to licentiates of the Pharmaceutical Society and to no others.

"2. Can physicians' prescriptions be legally compounded in Ireland by a firm of whom one or more members are not qualified pharmacists; or does the licence only extend to the individual licensee who conducts his business on his own premises and for his own profit?

"3. Can a firm in general business or co-operative society conduct a dispensing department under the management of a qualified pharmacist within their own premises, even though such qualified manager is the ostensible owner of said department?

"4. Can Mr. Hardy in the case specially referred to be regarded as a pharmaceutical chemist legally keeping open shop in the terms of the Society's regulation referred to?"

"*Opinion*: Having regard to the Statute 13 and 14 Victoria, chap. 21, sec. 4, words in the singular used in a statute include the plural and therefore 'person' includes 'persons.' As regards Mr. Hardy's case, having regard to the fact that he is the sole proprietor, as I understand, of the dispensing portion of the business, I think he may be fairly regarded as 'keeping open shop' within the meaning of the regulation at page 55 of the Calendar.

"As regards the second question in the case, in my opinion if a firm, not being an incorporated company, consists of persons, some of whom are not properly qualified pharmacists, such firm cannot legally compound prescriptions. In such case the licence granted only extends to the person to whom it is granted, so as to authorize him to conduct business on his own premises.

"As regards the third question in the case, I assume it refers to the case of firms or societies incorporated under the Companies Acts or otherwise. As regards such companies, having regard to the decision of the House of Lords in the case of the Pharmaceutical Society of Great Britain *v.* the London and Provincial Supply Association, Limited, 5th Appeal Cases, p. 857, they may keep and conduct a dispensing department provided the person actually managing and conducting such department is himself a properly qualified chemist.

"Reply to fourth query as to Mr. Hardy: I think he can."

The President: This reply is in some respects a rather serious thing for the Society, and shows the necessity for pressing for an amendment of the law. It appears to be an extraordinary anomaly that Brown, Jones or Robinson if they form an incorporated society can do what none of them individually can do by himself.

Mr. Draper: It is a *reductio ad absurdum.*

Dr. Aquilla Smith: The whole thing amounts to an evasion of the Act of Parliament.

Mr. Hayes: I suppose Sir John Arnott and Co. could set up a dispensing establishment in their house.

Mr. Draper: They could, because they are a limited liability company.

The President: Among the proposed amendments in the Act we have propositions touching this very point. The English Society have in their draft Bill a similar clause, which, it is to be hoped, will be passed into law. I have written to the President of the English Society asking for a copy of their draft Bill of this year, as I do not know whether any change has been made in it since last year. The first practical result of the communication we have received is that we must inform Mr. Hardy that, as the law has been interpreted to us, the course which he has adopted is not contrary to law. In Mr. Hardy's last communication to the Council he took exception to some remarks that I had made at a meeting of the Council and required me to withdraw them. I have nothing to withdraw. What I said I still adhere to, namely, that

Mr. Hardy had made elaborate preparations to evade the law, whether successfully or not remained to be seen. It appears now that he is so far successful, according to the way in which the law has been interpreted. I withdraw nothing that I have said. I do consider it an evasion of the law.

Mr. Grindley said he was averse to giving Mr. Hardy any answer in the matter.

The President said it was only right that a copy of the queries and answers should be sent to Mr. Hardy. Of course a lawyer's opinion did not settle the law. That could only be done by the decision of a Court of Justice; but he thought it would be unwise for the Council to go into Court with that opinion staring them in the face.

Mr. Allen: Can a person situated as Mr. Hardy is call his portion of a shop a "dispensing establishment?" It is really an establishment in itself according to the position which Mr. Hardy takes up. Questions may arise in the case of apprentices, as to what department they were engaged in.

The President said there was a clause in the proposed amended Bill empowering the Registrar of the Society to send to any questionable establishment a notice requiring the *bonâ fide* proprietor to state within a limited time who he is. For default in the making of that reply a penalty was provided; and also for carrying on business, and acting as owner, during default in making such reply a penalty was provided. This would be a most useful clause.

It was then resolved, on the motion of Mr. Hayes, seconded by Mr. Evans—

"That a copy of case and replies be forwarded to Mr. Hardy."

A letter was read from Mr. Robert J. Downes, suggesting alterations in the bye-laws of the Society.

The letter was referred to the Law Committee.

The next business was the consideration of a report from a deputation which had recently waited on the Chief Secretary for Ireland in reference to the amendment of the Pharmacy Act.

The President said they might take the report which appeared in the *Freeman's Journal*, of what occurred at the deputation, as it appeared to be the most accurate. All who attended the deputation must have been pleased at the favourable reception which they got from Mr. Trevelyan. He appeared to have gone thoroughly into the questions, and took up the points that were presented to him at once. He (the President) had not expected that before they left the room they should have received what was tantamount to a pledge, that, as far as possible, what they asked for would be carried out. The Chief Secretary asked them to put in writing exactly what they wanted, and the sooner that was done the better. He (the President) had drafted the heads that had already been agreed on by the Council, and had written to the President of the English Society, asking for a copy of the Bill which his Council were promoting, in order that the two Societies might, as far as possible, work on the same lines. If Government should bring in Bills for the two countries at the same time it was probable that the two Bills would be identical in some points. It was desirable to have a meeting of the Pharmacy Act Amendment Committee as soon as possible, in order to prepare the written statement for which Mr. Trevelyan had asked; it was also advisable that that statement when agreed upon should be printed, and copies of it sent to Irish members of Parliament.

Professor Tichborne said it would be very wrong to force a Bill through Parliament without consulting and getting the opinions of the members of the Society generally. The Council would not be bound to follow out whatever might be agreed to at a general meeting; but they were bound to place not only their own opinions but those of members of the Society generally before the Chief Secretary.

On the motion of Mr. Allen, seconded by Mr. McIlwaine, it was resolved that the Pharmacy Act Amendment Committee be requested to draw up, for the information of the Chief Secretary for Ireland, a *résumé* of the views of the Council as to the amendment of the present pharmacy laws.

A report was submitted by a committee to whom the subject of the supply of the *Pharmaceutical Journal* to the members of the Society had been referred. It was recommended that, as the finances of the Society did not justify so large an expenditure, the proprietors of the Journal should be asked—(1) if any further reduction could be made in the cost of supply; (2) whether in the event of the Society discontinuing the present arrangement they would supply the Journal to such members as desired to have it, on the same terms as at present, on being guaranteed a certain number of subscribers. The report stated that the latter of these courses was the one which the Committee would prefer.

After some discussion,

On the motion of Professor Tichborne, seconded by Mr. Hayes, it was ordered that the inquiries suggested by the report should be made before it was adopted.

Mr. John Armstedt Ray, of 15, Nassau Street, Dublin, was elected a member of the Society.

Mr. Hodgson made a statement, the effect of which was that £160 worth of stock had been sold out to meet the expense of fitting out the Society's new premises; that £128 had been expended; and that one bill remained unfurnished, the amount of which would probably not exceed £30.

Some accounts having been ordered to be paid, the Council adjourned.

The following gentlemen passed the examination for the licence as Pharmaceutical Chemist, held on January 2 and 3, and were registered as such on February 6:—

James Guiler, 25, High Street, Belfast,
William James H. Madden, Circular Road, Dublin,
David Stranaghan, 141, York Street, Belfast.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the Executive Committee was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on Friday, February 8, at 12.45 p.m.; Mr. John Harrison (Sunderland), President, in the chair; Mr. Cross (Shrewsbury), Vice-President.

Present—Messrs. Andrews (London), Arblaster (Birmingham), Barclay (Birmingham), Chapman (Scarborough), Churchill (Birmingham), Hampson (London), Holdsworth (Birmingham), Jervis (Sheffield), Jones (Llanrwst), Mackenzie (Edinburgh), Mason (Liverpool), Parker (Nottingham), Paterson (Aberdeen), Southall (Birmingham), Symes (Liverpool), Williams (Manchester), Yewdall (Leeds), and the Solicitor.

The minutes of the previous meeting of the Executive were read and confirmed.

The Secretary said in accordance with the instructions of the Executive he made arrangements for a deputation from the Association to wait upon the Commissioners of Inland Revenue at Somerset House, for the purpose of urging upon them the advisability of issuing an order making it compulsory on Excise officers, when purchasing spirit for analysis, to leave with the seller a portion of the spirit sold. The interview took place on September 25 last, and the following general order had since been issued from the Inland Revenue Office:—

"Ordered—

"That the attention of the service be directed to the following matters:—

"First. Samples of methylated spirit or finish.—Officers purchasing samples of methylated finish or methylated spirit from persons not licensed to retail methylated spirit are to obtain not less than one pint and a half, and this quantity is, in the presence of the trader, to be divided into three equal portions in accordance with the general instructions on the subject of samples. Sound corks are to be used and tied down with string, the knot being placed in a notch in the top of the cork and sealed. One of the subdivided samples to be offered to the trader (who should be informed that a sample will be tested as to the amount of resin, if any, dissolved therein), and a second is to be retained by the purchasing officer, and the remaining sample is to be sent at once to the laboratory for analysis.

"Any such purchase is to be reported without delay in order that the trader may receive early notice of any offence against the law.

(Signed) "CHAS. B. FORSEY."

The report of the Finance Committee was then received and adopted.

The Secretary was then instructed to prepare a statement showing the cases of prosecution and defence in which the Association had taken part, since its formation in 1876, together with the total expenditure during the same period, and to issue a print of the same with the annual report in May next, accompanied by a circular appealing for additional support for the Association.

The President said that at the last meeting of the Executive a deputation was appointed to wait upon the Pharmaceutical Council in reference to the proposed amendments of the Pharmacy Act. That the interview had taken place on November 6 last, and that the proceedings, at the request of the President of the Pharmaceutical Society, were not reported. At that interview a long discussion took place on the amendments proposed by the Executive of the Association to the Draft Pharmacy Bill prepared by the Pharmaceutical Council, when it was ascertained that the Council had already settled the lines of the measure with the Privy Council. Since that time, he and the Vice-President had, at the request of the President of the Pharmaceutical Society, again waited upon the Law and Parliamentary Committee of that body in reference to the matter, and a communication had been received from the Society which the Secretary would now read.

"Pharmaceutical Society of Great Britain,"
"17, Bloomsbury Square, London, W.C.,
"*January* 24*th*, 1884.

"The Secretary,
"Chemists and Druggists' Trade Association of
"Great Britain, Birmingham.

"Dear Sir,—It has been decided by the Council that it is desirable to ask the Privy Council to receive a deputation to urge the importance of introducing a Bill to amend the Pharmacy Act this session.

"With reference thereto, I am instructed to invite the Executive Committee of your Association to appoint a small deputation to accompany a deputation from the Council of this Society, and possibly others, to the Lord President of the Privy Council in support of legislation on the basis of the Bill now in the hands of the Government. "I am, yours faithfully,

(Signed) "ELIAS BREMRIDGE,
"*Secretary and Registrar.*"

After a very long and full discussion the following resolutions were passed:—

"That a small deputation be appointed to accompany a deputation from the Council of the Pharmaceutical Society to the Lord President of the Privy Council in supported of legislation on the general basis of the Bill to amend the Pharmacy Act now in the hands of the Government."

"That the deputation consist of the President, Vice-President, Mr. Barclay and the Secretary."

"That the officers of the Association, together with Messrs. Arblaster, Barclay, Hampson and Holdsworth, be appointed a committee to watch the progress of the Bill to amend the Pharmacy Act Amendment Bill in its passage through the Legislature."

It was moved by Mr. Mackenzie, seconded by Mr. Chapman, and unanimously resolved—"That the Eighth Annual General Meeting of the members of the Association be held in London on Tuesday, May 20 next, and that the arrangements for the same be left in the hands of the London Committee."

Mr. Jervis gave notice that at the next Annual Meeting he intended to bring forward a resolution proposing to amend Rule 6, so that for the future the officers of the Association should be elected by and from the Executive Committee instead of by the Annual Meeting as heretofore. He said he thought that it was very advisable that the Annual Meeting should elect the Executive Committee, but that, in his opinion, the Executive should be permitted to elect their own officers.

Mr. J. C. Arnfield was then appointed Local Secretary to the Association for Ashton-under-Lyne and district, *vice* Mr. William Bostock, resigned, and Mr. R. Newby, Local Secretary for Truro and district, *vice* Mr. Serpell, resigned.

A communication was read from Mr. Pipe, of 1, King's College Road, London, N.W., enclosing a donation of a guinea to the funds of the Association, and thanking the Executive for defending him in the action under the Sale of Food and Drugs Act recently brought against him by the parish authorities, and a similar communication from Mr. Sidney Allchin, of England Lane, London, N.W., enclosing a donation of five guineas towards the funds of the Association.

The President called attention to the retirement of Mr. A. H. Mason from the Executive Committee, as he was now about to leave this country for Canada, and bore testimony to the important services rendered by that gentleman to the Association.

On the motion of the President a resolution was passed acknowledging the value of the services rendered by Mr. Mason, and expressing a wish for his future welfare.

Several letters were read from members of the Association, and instructions given to the Secretary as to the manner in which he should deal with the same.

ABERDEEN CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A meeting of this Association was held on Friday, January 25, in the Chemistry Class-room, Marischal College, when Professor Brazier, F.C.S., Aberdeen University, delivered a lecture on "Vacuum Tubes."

In introducing the subject, reference was made to the phenomena of induction and electro-magnetism; then followed a description of the intensity coil, and a comparison was drawn between it and the electrical machine with reference to the subject in hand. The Professor then proceeded to illustrate the lecture by showing his splendid collection of tubes, pointing out any peculiarity connected with each. The fluorescence of quinine, the probability of producing light by means of tubes, and the phosphorescence displayed by several, after the current had ceased, were briefly touched upon. After further consideration of the subject, he remarked that although many of the experiments shown appeared of no practical use, still it was very probable that further investigation might prove them to contain the germs of future important discoveries.

Bailie Paterson, at the close of the lecture, in a few felicitous remarks, proposed a vote of thanks to Professor Brazier, which was heartily accorded.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The seventh meeting of the sixth session was held in the Pharmaceutical Society's rooms, 119A, George Street, Edinburgh, on Wednesday evening, January 30, at 9.15; Mr. Claude F. Henry, President of the Association, in the chair.

The minutes of the previous meeting having been read and confirmed, the Chairman called upon Mr. John R. Hill to read a paper on the "Official Alkaloids."

After giving a brief historical *résumé* of the various and important discoveries in alkaloidal chemistry since Sertürner in the year 1804 discovered the alkaloidal properties of morphia, Mr. Hill, taking the official alkaloids in their chronological order, proceeded to describe their chemistry and preparation, and illustrated his subject with a number of experiments, showing the principal reactions with colour reagents and precipitants, and described by means of graphic formulæ the artificial formation of bodies analogous to alkaloids.

The Chairman, in proposing a vote of thanks to Mr. Hill, referred to the amount of valuable information which he had brought before the meeting, and illustrated as the paper was by such elaborate experiments, he was confident it had been both interesting and instructive to the members.

Mr. MacEwan seconded the motion, which was cordially awarded.

A discussion followed, in which Messrs. Crowden, Thomas, Stephenson and Turnbull took part.

Mr. Hill briefly replied.

A number of queries were then submitted and replied to by Messrs. Hill, MacEwan, Robbie and Turnbull.

The Chairman having intimated that at the next meeting Mr. Wm. Pirie will read a paper on "Mineral Waters," the meeting adjourned.

The first annual *soirée* and assembly of this Association was held on Friday, the 1st inst., in the large hall of the Literary Institute, South Clerk Street, Edinburgh. The hall was effectively decorated with flag trophies, bannerets, etc., and when the company, numbering about two hundred, had assembled, it presented a very gay appearance. At half-past eight o'clock, the chair was taken by the President of the Association (Mr. C. F. Henry), who was accompanied to the platform by Dr. Inglis Clark, Messrs. Aitken, Beaumont, Fidler, MacEwan, Robertson, Turnbull and others.

After reading letters of apology from Mr. John Nesbit, (President of the North British Branch) and Mr. J. R. Young, the Chairman proceeded to give a welcome to the guests. In the course of his remarks he stated that the annual reunions which the Association had previously had were found to draw out only a portion of the young pharmacists of Edinburgh and district, while ladies were entirely excluded. It was with the hope of further extending the brotherly feeling which the Association could lay fair claim to have engendered in local pharmacy that the reunion had been remodelled. He now gave the ladies a hearty welcome in the name of the Association and hoped they would thoroughly enjoy the evening's entertainment which the Committee had provided. He concluded by remarking that the reunion was not merely an Association meeting, but was intended for all connected with pharmacy, and he hoped all would co-operate with the Association in making future reunions successful.

After tea had been served, a lengthy programme of vocal and instrumental music was gone through, humorous readings being also contributed.

After the completion of the programme, Mr. MacEwan in the name of the Association thanked the ladies and gentlemen who had contributed to the evening's enjoyment. The Committee had endeavoured to make the meeting an enjoyable one, and he was sure all could say it had been a success. At future meetings their efforts would be extended and everything done to make the reunions a feature in Edinburgh pharmacy.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

The second monthly meeting of the session was held in the Owens College on Tuesday evening, January 29. Mr. F. Baden Benger, F.C.S., in the chair. There was a good attendance.

The Chairman, in opening the meeting, congratulated those present on being able to assemble in one of the lecture theatres of the college amongst so much that was interesting to pharmacists, and reminded them that they were indebted for this privilege to the Council of the Owens College, who were anxious to afford every facility to those who would avail themselves of the splendid opportunities for the study of materia medica and pharmacy now provided. He then called on Mr. W. Elborne to read his paper on—

Cinchona Barks.

BY WILLIAM ELBORNE,

Assistant Lecturer on Materia Medica and Pharmacy, Owens College.

The author, having described the important genus *Cinchona* botanically, stated that upwards of thirty-six species of *Cinchona* had been distinguished, but that only about a dozen furnished the barks of commerce. These were principally natives of the western mountainous regions of South America.

The chief varieties were enumerated as follows:—

			Their characteristic alkaloids.
I.	*C. officinalis*,* var. *a. Condaminea*, *b. Bonplandiana*, *c. crispa*	yielding pale or crown bark	Quinine.
II.	*C. Calisaya*,* yielding yellow bark		Quinine, Cinchonine.
III.	*C. Ledgeriana*, yielding Ledger bark		
IV.	*C. succirubra*,* yielding red bark		Cinchonidine.
V.	*C. lancifolia*,* yielding soft Colombian, Carthagena or Caquetta bark; *C. cordifolia*, yielding hard Colombian bark		Quinine.
VI.	*C. Pitayensis*, yielding Pitayo bark		Quinidine.
VII.	*C. nitida*, *C. micrantha*, *C. Peruviana*	yielding Huanuco, Lima or grey bark	Cinchonine.
VIII.	*Remijia pedunculata*, *Remijia Purdieana*	yielding Cuprea bark	Quinine, Quinidine, Cinchonine, Cinchonamine.

The methods of collecting bark in the native forests of South America having been described, the author traced the history of Cinchona cultivation in India, Jamaica and Ceylon, giving statistics of the areas under cultivation, etc. Of the countries where bark is cultivated Ceylon was, perhaps, the most important, although great efforts in the same direction were being made in Bolivia, Java, Jamaica and Southern India.

* The official barks of the British Pharmacopœia.

The manner of growth and the operations of collecting and harvesting the "cultivated barks," whereby the yield of alkaloids was greatly increased, were then alluded to. They comprised two different systems, viz., "mossing" and "coppicing."

The "mossing" system consisted in longitudinally stripping eight-year old trees of their bark at intervals of about two inches apart, winding moss all round and tying it on with fibre. At the end of six or twelve months the strips of bark left untouched at the first stripping were removed, and the intervals they occupied were mossed. At the end of twenty-two months, on an average, the spaces occupied by the bark originally taken are found to be covered with renewed bark, much thicker than the natural bark of the same age, and this renewed bark can be removed and a fresh process of renewal again be fostered by moss. The enrichment of the renewed bark is said to be at the expense of the bark outside the mossed region, and also that the renewal is prevented or much retarded by the least injury to the cambium. The protection from light afforded by the moss has also been proved to increase the supply of alkaloids.

The "coppicing" system consists in cutting down the trees near the ground and allowing one or more of the young crops of the shoots which rise from the stumps to grow. The trees are barked at the proper season by coolies, to whom the felled stems and branches are made over as soon as they are cut. Provided with a stout knife, the coolie first marks the bark off into long narrow strips by putting his knife under it and pressing upwards. The end being freed, the remainder of the strip readily comes off; the bark is then laid to dry in sheds fitted with shelves.

The author next proceeded to describe the characteristic appearances of the above series of barks, drawing special attention to their "fracture." He stated that the manner in which the cinchona barks break transversely, or their fracture, depended upon their anatomical structure, and afforded an important criterion of the quality of the bark; the best characteristics by which barks containing much quinine might be distinguished were the *shortness* of the fibres which covered their transverse fracture and the facility with which they might be detached. Thus when dry *Calisaya* was handled a quantity of minute splinters ran into the skin causing much irritation; this forms one of its distinguishing marks. The following is a table of the official barks compared with the corresponding cultivated bark:—

	Barks of South American origin.		Cultivated barks (India, Ceylon, Jamaica, etc.		
	How found in commerce.	Remarks.	How found in commerce.	Remarks.	
C. Calisaya .	Flat pieces	Trunk bark, outer layers removed, consists of *liber*, yellow colour, upper surface marked with digital furrows, under surface with long wavy fibres (thickness of hair). Fracture short, finely fibrous. Bark at present very scarce.	. . . .	Cultivation unsuccessful, consequently abandoned.	
	Quills	Bold, outer surface cracked at intervals of 1 inch, remains of lichens, short yellow fracture.			
C. officinalis .	Quills only	Thin, slender, interspersed throughout with cracks and numerous lichens.	Quills only	In pieces less quilled than the South American, thicker, outer surface, perfectly clean (grown under moss), no lichens, inner surface of a light fawn colour. Jamaica variety black, very corky, no lichens (var. *crispa*).	Yield 6–8 per cent. total alkaloids. *C. succirubra*, best bark for pharmaceutical purposes.
C. succirubra .	Flat pieces	Trunk bark, corky layers not removed. About 1 inch in thickness, very dull red colour, contains scarcely any alkaloid (having been converted into red colouring matter by prolonged action of light). Mostly exported to France.	Quills only	The very large quills taken from stems, red colour internally, remains of lichens. The smaller quills plump, red colour, clean outer surface, no lichens (mossed bark). Also in thin papery quills, purplish colour externally.	
	Quills	Large, red colour, remains of lichens.			
C. lancifolia .	Flat pieces	Trunk bark, consists of liber with silvery remains of mesophlœum. Long fibrous fracture. This bark, together with flat pieces of *C. micrantha*, sold as flat Calisaya in commerce.		Not cultivated.	
	Quills	Very large, outer layers generally removed, yellow colour.			

The various processes for estimating cinchona barks were then described, the paper being illustrated throughout with specimens of barks and alkaloids from the Materia Medica Museum, Owens College.

After the reading of the paper a discussion ensued in which the Chairman and Mr. Hermann Woolley took part.

Mr. Elborne having replied, the Chairman, in moving a cordial vote of thanks to Mr. Elborne for his most interesting paper, said he would take that opportunity of expressing the pleasure he felt in seeing so many young men present. During the sixteen years he had acted as Honorary Secretary of that Association lectures had been given and classes had been held with varying success. The tide of interest had ebbed and flowed; sometimes the classes had been very numerously attended and then there would come a dull and spiritless time. He hoped the present meeting augured well for the success of the pharmaceutical courses now being established in connection with the college, and that they were now entering on a period of something like enthusiasm. In glancing at the results of the educational efforts of the Manchester Association as a whole, he found many sources of satisfaction. A large number of students had derived valuable assistance in their studies, and some had become prominent men. Happily most of these were still living, and their modesty would be offended if he mentioned their names; but there was one, the late Dr. Carruthers, whose sad fate they all lamented, and whose memory they honoured. He remembered in the early days of the Association, a young apprentice from a country town came to him for the keys of the materia medica cabinet belonging to the Association, a very poor affair compared to the museum now open to students in the college, but still worth the young man's while to come a railway journey to see and work at. That apprentice was now a Doctor of Science of the London University, a recognized authority in chemistry, and, he was happy to add, still a pharmacist. There was probably not an apprentice in that room who could not do as much if he worked as hard, for it was by no royal road that this country apprentice had risen.

Mr. Robinson, of Pendleton, in a few appropriate remarks congratulated the meeting on the good attendance that evening, and had great pleasure in seconding the vote of thanks to Mr. Elborne for his admirable paper, which was carried with acclamation.

The Chairman then announced that two papers had been promised for the March meeting, but that February was still open. He nevertheless hoped one or more contributions would be received in due time.

The meeting then terminated.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The annual meeting of the above Association was held in their room, Church Institute, on Thursday evening, February 7. Mr. Martin, President, occupied the chair.

The Secretary (Mr. C. G. Wood) read the report of the year, which stated that the society was in a prosperous condition. There had been classes held each Tuesday evening on the subjects of Chemistry, Materia Medica, Pharmacy, etc.; these had been well attended. The classes are conducted under the superintendence of the President. A portion of study for preparation at home is given each week, and the practical portion of Chemistry is worked by the members themselves at the meetings. There have also been numerous papers read by several friends and by many of the members, the attendance at the meetings being highly satisfactory.

The Treasurer (Mr. Swinburn) was then called upon to give his financial statement, which showed that the Association was in a prosperous condition, as after all expenses had been paid there was a fair balance in hand. It ought to be stated here that the expenses are borne by the members themselves, with the exception of one donation from the Local Secretary of the Pharmaceutical Society.

The President then delivered his address.

After some preliminary remarks, he referred to the presence of a delegate from the Association at the last meeting of the British Pharmaceutical Conference, and then continued:—"But the mere fact of sending a delegate is not what we want; we want to profit by his attendance, we want to know how with our small ability we can help in the forward march of progress. Some people may be disposed to laugh at and ridicule this idea, but it is a square matter of fact idea nevertheless. Most of the subjects recommended for investigation are far above our attainments, but there are some which are quite in our province as willing students,—I mean such things as the best excipients for B.P. pills, the most satisfactory basis for ointments, or some such subject as the deposit in tr. quiniæ comp. In these cases we can all work together and, each taking one particular section of the subject, make himself master of that, and report his results to a general committee, who could tabulate the whole, and thus a quantity of useful information could be collected that doubtless would be of use to more advanced workers. There are other ways in which associations such as ours can be of service to the pharmaceutical body. For instance, the local papers which contain items, useful or interesting to chemists, might be sent to the trade journals, for they cannot be expected to hear of everything that occurs, and thus inquests, the cases of malicious or accidental poisoning, the doings of illegal traders, or of those of our own body who disgrace us would have the full benefit of publicity, a thing too often wanting, There is another point on which I should like to speak, and that is the future of the chemists of this country. I, for one, take no gloomy view of the situation; things are bad, I know, but I believe that we are in a state of evolution, and that the fittest will survive, and the weakest go to the wall. No doubt it is bad for the weak ones, but good for society at large. The name of chemist will be all the brighter and more respected when evolution has obliterated that dreary type of druggist, the huckstering rule of thumb man, whose highest aim in life was a cheap thing in hair oil or glue, who fixed his simple faith on mucilage or ext. gentian. as an excipient for pills, and who dispensed a mixture when he got one on the happy-go-lucky plan of dropping the ingredients into a bottle, filling up with water and letting them take their chance. The chemist of the future will be a chemist in more than name, an enlightened educated man, respected by the medical profession and cultivating new fields of enterprise brought to light through increased knowledge. And it is to this type we must try and attain, and it is for this reason that I throw in my lot with the Pharmaceutical Society, as I believe their efforts will bring about this desirable state of things. Many of you, I know, already subscribe to the Society, and I should be glad if the rest would do the same, for your help is useful, and in years to come, when you are in business for yourselves, the volumes of the Journal will prove a useful library for reference."

After the election of the following officers and revision of rules, the meeting terminated:—Mr. Martin, President; Mr. W. Buckley, Vice-President; Mr. C. G. Wood, Secretary; Mr. Swinburn, Treasurer. In each case the officer of last year was re-elected.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, February 7. Dr. W. H. Perkin, F.R.S., President, in the chair.

The President announced that a ballot for the election of Fellows would take place at the next meeting of the Society (February 21).

The following certificates were read for the first time:—Messrs. F. W. Brown, J. E. London, G. A. Parkinson, G. Tunbridge and T. U. Walton.

The Secretary then read a paper—

On the Expansion of Liquids, By D. MENDELEJEFF; translated from the Russian by B. BRAUNER.—Though every liquid has its own peculiar coefficient of expansion a general expression for the expansion of all liquids has long been a desideratum. The generalization now given by the author is founded on the additional experimental material collected by chemists chiefly for the purpose of studying the specific volumes of liquids at their boiling temperatures. In the present paper only the physical side of the question is discussed. Most of the data are derived from Thorpe's paper (*Chem. Soc. Journ. Trans.*, 1880, p. 141). The uniformity in the expansion of liquids, shown by the examples given in numerous tables, may be represented by the formula—

$$V=\left(1+\frac{K}{n}t\right)^{n}$$

which is the same as that giving (according to Gay Lussac's law) the expansion of gases. For gases, $n=+1$; for liquids, $n=-1$. The expression for liquids becomes therefore $V=(1-Kt)^{-1}=\frac{1}{1-Kt}$, and as the specific gravities are inversely proportional, if D = density at t and Do the density at 0°, then $D=Do\ (1-Kt)$. The author then gives several examples of the close agreement obtained with the above formula and the experimental results of Thorpe. Thus with phosphorus tribromide according to Thorpe—

t=	40°	60°	80°	100°	120°	140°
V=	1·0348	1·0530	1·0720	1·0916	1·1123	1·1340
V calculated	1·0348	1·0531	1·0721	1·0918	1·1123	1·1325

($K=0·000841$). The author discusses the varying values of K in the exceptional case of water at different temperatures. The results of the paper may be summed up as follows:—In the expansion of liquids a peculiar regularity and a quantitative uniformity are observed, and the equation given above may be taken as an approximation to reality, K being a constant coefficient characterizing each liquid, as the specific gravity, the boiling point, etc. The author proposes to call K the determinator of expansion, and suggests that a determination of its value under different conditions is extremely important for the mechanics of liquids. The expression given above, although many liquids deviate slightly from it, is by itself sufficient in the majority of physico-chemical investigations, just as Gay Lussac's law is sufficient for most physico-chemical work with gases.

Dr. Morley said if the expression held with two liquids it ought to hold with mixtures. He examined some time back the expansion of hydrocarbons from petroleum and found that K first increased, then decreased; such a phenomenon could not be explained if the law was rigorously true.

Dr. Armstrong read an extract from a letter of Dr. Thorpe, who had seen the paper, in which he expressed his satisfaction that the physical data which he had been at some trouble to obtain should have formed the basis of such an important paper.

The President then called on Mr. R. Meldola to read a paper entitled—

Researches on Secondary and Tertiary Azo-Compounds. No. II.—The author describes in this paper, in continuation of his former researches, the action of diazotized paranitranilin upon tertiary monamines. In the case of dimethylanilin the resulting product is paranitrobenzenazodimethylanilin $NO_2C_6H_4N_2C_6H_4NMe_2$, and this on reduction by ammonium sulphide furnishes the corresponding amido compound. The amido group in the latter is easily diazotized and can be combined with phenols so as to form a new series of secondary azo compounds. Para-amidobenzenazodimethylanilin is a most delicate test for nitrous acid; when diazotized and then neutralized with ammonia a fine blue colour appears. By this test 1 part of sodium nitrite in 64,000 of water has been detected. The next portion of the paper deals with the action of diazotized metanitranilin upon primary, secondary and tertiary amines. The nitroazo compounds of the meta series could not be reduced by ammonium sulphide without complete decomposition, so that this method could not be applied for the preparation of secondary and tertiary azo compounds as in the para series. The β-naphthylamine compounds both of para- and meta-nitrodiazobenzene cannot be further diazotized by the action of nitrous acid, but furnish nitroso derivatives. From this fact the author concludes that an amido group is no longer present in these compounds, and assigns to them the constitutional formula—

$$C_6H_4\begin{cases} NO_2 \quad H \\ \qquad\quad\ | \\ N - NC_{10}H_6NH(\beta) \\ |\underline{\qquad\qquad\quad}| \end{cases}$$

A comparison of the melting points of the β-compounds both of the para and meta series also favours the view that they are differently constituted to the true nitroazo compounds derived from α-naphthylamin.

Dr. Armstrong thought the constitution suggested by the author highly probable; he had noticed with the naphthols the very marked difference between the α and β bodies.

Mr. Meldola, in answer to several questions, said that all the bodies were more or less coloured, but the more complex the body became the duller the colour seemed to be; there seemed to be a tendency to become bluer as the complexity increased. The difference between the α and β compounds seemed to depend on the fact that the most readily displaced hydrogen atom in the latter compounds was the contiguous ortho atom, so that we were really dealing with an ortho compound.

The Secretary then read a communication entitled—

Note on the Nitrogenous Matters in Grass and Ensilage from Grass. By E. Kinch.—The object of the author was to determine whether during the fermentations to which grass and other fodder crops are subjected in order to produce ensilage, the albumenoids undergo any change into other nitrogenous bodies not possessing the physiological functions of albumenoids; for although the exact nutritive value of these non-albumenoid nitrogenous bodies is as yet unknown, it is certain that they can only replace the true albumenoids in food to a limited extent. The sample of grass was taken during the filling of the silo, on July 17, 1883; the grass was coarse and contained notably thistles and *Ranunculi*; it was passed through a chaff-cutting machine. The weight on the silo was about 50 pounds per square foot. The ensilage was taken out on December 8. It was brown, scarcely acid, and had but little odour; it soon, however, developed a smell of acetic acid, which was subsequently replaced by that of butyric acid. It was readily eaten by cattle when mixed with dry fodder. The author gives detailed analyses of the grass and ensilage. The albumenoids were determined by the phenol, the copper hydrate, the mercuric hydrate and the lead hydrate methods. The most striking change was in the relative quantities of the albumenoids and non-albumenoids. In the grass the non-albumenoids formed but 9 per cent of the total nitrogen; in the ensilage the non-albumenoids had increased to 55 per cent. of the total nitrogen. So that during the fermentation in the silo nearly half the albumenoid nitrogen had been converted into non-albumenoid. Whether such changes in the nitrogenous matter always take place or, as is likely, are diminished in extent by increasing the pressure to which the fodder is subjected, and what nitrogenous bodies are produced, are questions which the author hopes to answer in a future paper.

Professor Church said that he had found it advantageous to add a little metaphosphoric acid, when employing his phenol process, if the material was at all alkaline.

Mr. Vincent mentioned some experiments in which cows had been fed alternately on ordinary food and on ensilage. The weight of the cows remained constant, but when fed on ensilage the cows furnished on an average two gallons of milk more per diem. He also could confirm the fact that ensilage from clover has a most powerful odour of butyric acid.

Mr. Warington said that it was hardly possible to overrate the practical importance of ensilage. As far as he knew, Professor Kinch had been the first to determine the relative quantities of albumenoid and non-albumenoid nitrogen in ensilage. There had been many analyses of grass and ensilage published, but no one yet had really made a quantitative experiment, *i.e.*, weighed all the grass which went in and the ensilage produced. We were also very much in want of analyses of foods as to the relative quantities of albumenoid and non-albumenoid nitrogen which they contained.

Mr. Friswell suggested that the experiment quoted as to the increase of quantity of the milk was of but little value unless the quality of the milk, as ascertained by analysis, was known.

Dr. Armstrong said it would have been interesting to know the quantity of nitrogen liberated by hypobromite.

Mr. Lloyd had endeavoured to investigate the form taken by the nitrogen, but had hitherto been unsuccessful. If too much pressure was used much nutritive juice was squeezed out of the grass. The great aim should be to avoid an acid fermentation.

The Secretary then read a paper on—

The Influence of the Temperature of Distillation on the Composition of Coal Gas. By L. T. Wright.—The author distilled a carefully mixed sample of Newcastle coal in a small iron retort; the charge was 2·24 lbs and the distillation occupied twenty-five to forty-five minutes. Four experiments were made at various temperatures; with the lowest temperature 8250 cubic feet of gas per ton of coal were obtained of 20·5 candle power; at the highest temperature 12,006 cubic feet, illuminating power 15·6. The gas in the first case contained 38·09 per cent. H, 8·72 per cent. CO, 42·72 per cent. CH_4; 7·55 per cent. other hydrocarbons and 2·92 per cent. N. The gas obtained at the highest temperature contained 48·02 per cent. H, 12·96 per cent. CO, 30·7 per cent. CH_4, 4·51 per cent. hydrocarbons, 2·81 per cent. N. The author discusses the influence of marsh gas, carbonic oxide, etc., on the illuminating power of the gas, and criticizes the experiments of Frankland and Thorne. In the second part of the paper the author gives some analyses of gas drawn from retorts at different stages of the ordinary process of gas manufacture. The results confirm those obtained by Dr. Henry.

Professor Foster said that apparently no analysis of the coal was given. He also gave an account of some experiments, which he had made, of passing steam over coke and thus liberating the nitrogen contained in it.

The Society then adjourned to February 21, when a ballot for the election of Fellows will be held.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the Chemists' Assistants' Association, held on Wednesday, January 30, Mr. C. Parkinson, President, in the chair, a paper was read on—

Turpentine.

BY F. HARRIS ALCOCK.

The introduction consisted of a general sketch of the Coniferæ and a description of the chief characteristics of that order, together with the numerous trees yielding turpentines. Special reference was made to the botanical sources, habitats, and characters of the pines which yielded the ordinary turpentine oleoresin. The methods of obtaining the oleoresin from the tree, both in the Landes department and in America, were fully described, and notes were read from various works bearing on the subject of extraction. The characters physical and chemical of the French and American turpentine were briefly described, and a complete description for obtaining the different oils from these sources was given, together with the mode of rectification, properties, composition, uses and adulterations of the oil. Of the last-named particular mention was made of the following, and the usual methods of detection enumerated:—Fixed oils, water, resin spirit or oil, undistilled turpentine, rosin, and petroleum spirit. With regard to petroleum spirit, mention was made of the recent correspondence and editorial jottings in the *Pharmaceutical Journal* on this subject. Dr. Armstrong's method for the detection of this adulterant, as was brought forward by him at a meeting of the Society of Chemical Industry, June 5, 1882, was fully explained, as also Mr. Boverton Redwood's suggestion with regard to the effect of this admixture on the flashing point test. A sample of turpentine oil examined by the author some time ago was found to be largely adulterated with petroleum spirit. Its presence was suspected because it was found that when used, mixed with paint, it caused severe illness to some individuals who happened to be in the house where it was being used. The sample had the odour and taste of turpentine oil and a specific gravity of ·8424. Ten c.c. evaporated over a water-bath were dissipated with the exception of 0·054 gram residue (of a light yellowish-green colour), in fifteen minutes. The liquid had a boiling point of 80° C. which gradually increased as the volatile portion distilled over, going towards the end of the process as high as 160° C. The residue in the retort was of an orange colour and resinous. Ten c.c. of the liquid distilled below 100° C. yielded about 3 grams weight of a colourless liquid which possessed only a faint smell of turpentine oil and was slightly fluorescent and had a smell which suggested petroleum spirit. By way of comparison several authenticated samples of oil of turpentine were obtained from different sources and subjected to the same treatment under the same conditions in order to satisfy the author that the oil of turpentine under examination was sophisticated, with the following result:—

	Quantity.	Sp. gr.	Residue.	Time to dissipate.	Boiling point.	Odour of distillate.	Remarks.
			Grm.	Min.			
A.	10 c.c.	0·8424	0·054	15	80° C. ending at 160°	Petroleum-like.	Adulterated samples.
B.	10 c.c.	0·8572	0·021	30	153·5° C.	Turpentine-like.	Re-rectified from KHO.
C.	10 c.c.	0·8807	0·328	63	158·° C.	,,	Old sample.
D.	10 c.c.	0·8746	0·048	45	155·° C.	,,	Ordinary sample.

The above data would enable one to pronounce unhesitatingly sample A as being impure, or, at least, what oil of turpentine should not be. If more of material were at hand the method to be adopted would be to obtain by fractionation what seemed to be "benzoline" or petroleum spirit and proceed with the distillate according to Dr. Armstrong's method.

In the discussion which followed, the President, Messrs. Braithwaite, Burnett and Millhouse took part.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association took place on Thursday, February 7, Mr. T. S. Dymond, Vice-President, in the chair.

The minutes of the previous meeting having been read and confirmed, a note was read on "The Crystallization of Phosphoric Acid," by Mr. P. L. Huskisson, which will be found printed on p. 644.

This paper was followed by a discussion in which the Chairman, Secretary, Messrs. Ince, Lowe and Short took part, and a vote of thanks was passed to Mr. Huskisson.

Mr. H. Allen, the Reporter on Physics, then made a report upon "Holtz's Electrical Machine and some of its Modifications." The report was illustrated by experiments and a number of machines of different forms were exhibited, the most noteworthy among which were the Voss machine, which was lent by Messrs. Becker, of Covent Garden, and the Wimshurst machine, both of which were shown in working order. A discussion ensued, in which the Chairman, Secretary, Dr. Jackson and Mr. Lowe took part.

The meeting then adjourned.

SOCIETY OF ARTS

Recent Improvements in Photo-Mechanical Printing Methods.

The second of the course of Cantor Lectures upon this subject was delivered by Mr. Thomas Bolas on Monday the 4th inst. It was devoted specially to the various methods of preparing type blocks from line drawings and half-tone subjects and some experiments were made illustrating the formation of Woodburytype blocks by which the gradation of tone in a subject could be represented. A sheet of gelatine paper, coated with albumen and sensitized with bichromate of potash, was exposed behind a negative for some time to a strong light. The sheet was then taken away and a thin layer of a prepared ink placed upon it; afterwards, upon being soaked in warm water, the insoluble gelatine retained the ink, whilst the soluble portion was washed away. The transfer thus obtained consisted of a fatty relief, which left an imprint upon the stone or on the lead, afterwards to be prepared by treatment with acid for use as a type block. Some illustrations were handed round showing the difference between those of 1851 and 1883. Those illustrations of the earlier date, which the lecturer regarded as the commencement of a new era in regard to printing, consisted of a mere outline, simply showing the position and figure of the subject, whilst those of 1883 had less outline, but were rendered life like by the shadows and perfect gradation of tone. Reference was then made to a method employed for some time in Australia, by which a sheet of glass covered with a layer of wax was used as a transfer and hydrofluoric acid as the biting agent. In the course of the lecture, Mr. Bolas drew attention to the use of rollers, remarking that the leather roller employed for ordinary lithographic purposes was useless in the preparation of photo-lithographic prints, and recommending that velvet rollers should be used, as the fibres of the velvet remained separate; he also stated that he believed letterpress printers would soon begin to use indiarubber in preference to the composition rollers. In order to give the same sharpness of outline to a large number of copies, the lecturer considered it necessary to take a fresh transfer from the first block and use the second transfer to obtain the type-block. At the conclusion of the lecture, Mr. Bolas noticed the method used by Ives to obtain the type-block. If a thick sheet of metal, the surface of which is cut by fine groves into small pyramids, be pressed against an ordinary type-block, a perfect impression is obtained from the flattening of the points of the small pyramids; it is found best to insert a thin piece of paper between the two plates to avoid damage to the type-block. During the lecture, Mr. Bolas showed a number of photo-lithographs sent from all the principal printing firms, and endeavoured to point out the peculiarities which each expressed.

The third and last lecture of the series was delivered on Monday the 11th inst. Mr. Bolas commenced by describing a modification of Ive's process. A plaster cast of the photograph is taken, and upon the wet relief a thin layer of collodion is spread, to which a little gelatine is added to give more consistency. After a little while the film is stript off and a perfect transfer is thus obtained. Regretting that he had no time to speak upon the subject of chromophotolithography, the lecturer passed on to the cavity or intaglio process. Any method by which a fatty transfer is obtained can be used for the intaglio process, the only alteration necessary being that a reverse transfer is required. Though a much better style of prints can be obtained by this process, yet the expense of working is so much increased, that it can only be used when a higher class of work is required. A transfer is taken, and from this an imprint is pressed upon grained paper; this is laid down on a copper plate and etched; or sometimes a block of wood with prepared surface is used instead of the copper plate. Reference was then made to the graining, Mr. Bolas saying that Mr. Woodbury had produced grained photo-prints by mixing a gritty substance with the gelatine, though his productions were somewhat spoilt by the use of a lead instead of a copper plate to print from. Good results, however, have been obtained by the Waterhouse process; the peculiarity of this method is the scattering over the wet relief of a quantity of fine sand, coated with stearin or wax to prevent it sticking to the gelatine. Great advance had been made in the transfer of photo-prints in pottery. The plates for printing are made in the same manner as for ordinary lithograph or typograph work, but it is necessary that they should be more deeply marked, in order to allow a larger body of ink to remain upon the pottery. There are two ordinary methods in vogue for the transfer from the plate to the pottery; one is to take a transfer with a thick viscid ink upon thin tissue paper; the inked paper is then attached to the pottery, and after a time the paper is washed off with warm water, leaving the ink upon the pottery; according to the other method the transfer is effected by means of glue. A good transfer is obtained also by producing a design upon a bitumen plate with thick viscid ink; upon exposure, the uncovered bitumen becomes hardened, whilst a depression is formed by the subsequent removal of the inked portion.

Obituary.

JOHN HUTTON BALFOUR, M.D., F.R.S.

On Saturday last Scotland lost by death one of her most eminent scientific sons in Dr. John Hutton Balfour, Emeritus Professor of Botany in the University of Edinburgh. Professor Balfour was an Honorary Member of the Pharmaceutical Society of Great Britain, the North British Branch of which was indebted to him for many courtesies shown whilst he was Regius Keeper of the Botanic Gardens, and especially in liberally supplying the Board of Examiners with fresh and preserved botanical specimens for examination purposes.

John Hutton Balfour was born in Edinburgh in 1808. He was early sent to the High School and matriculated at the University when thirteen years of age. First at St. Andrew's University and afterwards in Edinburgh his studies seemed to show a bent for the church; afterwards, however, he inclined towards medicine. But according to a writer in the *Scotsman*, from whom we borrow some details, his ultimate career was largely influenced by a course of lectures on botany delivered by Professor Graham in the University of Edinburgh in the summer of 1826. Having completed his medical studies he passed the College of Surgeons in 1831, received the degree of M.D. in 1832 and became a Fellow of the College of Surgeons in 1833. After some infirmary work in Edinburgh he visited Paris, returning to his native city and settling down as a medical practitioner in 1834. Two years subsequently he helped in founding the Botanical Society, to which he contributed so many of his memoirs, and in 1838 he rendered a similar service to the Botanical Club. Already, in 1840, he was a successful "extramural" lecturer on botany, and, in 1841, upon Dr. (afterwards Sir William) Hooker being appointed Director of the Royal Gardens at Kew, Dr. Balfour succeeded him in the chair of botany in the University of Glasgow, which he filled for thirty-four years. In the same year he became Regius Keeper of the Royal Botanic Gardens and Queen's Botanist in Scotland. Upon his retirement from the chair in 1879, Professor Balfour was succeeded by his second son, Isaac Bayley Balfour, who, only a few days since, was appointed to the Sherrardian Chair of Botany in the University of Oxford. The late Professor held several other offices and received many evidences from various bodies as to the high estimation in which he was held.

Professor Balfour was a somewhat prolific writer and several of his works, such as the 'Manual of Botany,' 'Elements of Botany,' and 'The Plants of the Bible,' are well known. Besides the larger works, he contributed a great number of memoirs on botanical subjects, several of which touched upon the domain of materia medica. Among these may be mentioned communications upon *Aconitum ferox*, *Narthex Assafœtida*, the Ordeal Bean of Calabar, *Atropa rhomboidea*, *Cephaelis Ipecacuanha*, etc.

SAMUEL FRANCIS ELLIMAN.

It is with deep regret we record the death, on the 25th ult., of Mr. S. F. Elliman, of Slough. Whilst riding across Englefield Common, in company with a friend, his horse suddenly bolted, and Mr. Elliman losing control over the animal was thrown and killed on the spot. Cut off in the prime of manhood, in the midst of a career of very varied usefulness, his loss will be keenly felt by a wide circle of friends both connected with, and outside pharmacy.

Mr. Elliman was apprenticed at the age of 17, to Mr. R. Griffith, pharmaceutical chemist, of Slough. At the expiration of his indentures in 1867, he sought experience in various pharmacies in Scarborough, Geneva and Paris. He was in the latter city during the greater part of the Franco-German war, only quitting it just in time to escape the horrors of the siege.

During the Session 1872–73, Mr. Elliman was a student in the School of Pharmacy, and in January of the latter year qualified himself as a Pharmaceutical Chemist. In the Laboratories, at Bloomsbury Square, he was deservedly popular, and few of his fellow-students will fail to recall his ardent love for physical phenomena, and the generous enthusiasm with which he was wont to describe to others the results of his own patient observation.

After spending some time at Nice and Florence, Mr. Elliman returned to Slough, and commenced taking an active part with his brother in the development of the business of Elliman, Sons and Co. In the intervals of business he found time to attend the lectures at the School of Mines, where he obtained a first-class certificate, and he spent some months in the physiological laboratories at South Kensington, under Professor Huxley, making himself practically acquainted with comparative anatomy. It was here he conceived the idea of illustrating anatomical subjects by means of stereoscopic photography. A few months' practice sufficed to enable him to master the most recent and approved photographic processes, and in the autumn of 1881 he proceeded to Lyons, where, by permission of Professor Chauveau, he was enabled to take photographs of the anatomical preparations used to illustrate the lectures at the Ecole Vétérinaire. On his return home he placed specimens of his work in the hands of Professor Flowers, who expressed his unbounded admiration of the conception and of the skill with which his idea had been carried out.

It was only a few hours before his death that Mr. Elliman was at the annual *soirée* of the Windsor and Eton Scientific Society, where holding in his hand a beautifully prepared skull, he explained to delighted groups of listeners, the marvellous construction of the human ear.

In his native town Mr. Elliman took a leading part in all movements calculated to promote the interests of education in its widest sense. He had provided, at his own expense, a gymnasium and swimming bath for the young men and boys of the neighbourhood, and was an energetic member of the Local Board and British School Committee.

Notice has also been received of the death of the following:—

On the 15th of November, 1883, at Melbourne, where he had gone in the hope of recovering his health, Mr. John Sydney Ashweek, Pharmaceutical Chemist, late of High Street, Gravesend.

On the 10th of December, 1883, Mr. John Andrews, Chemist and Druggist, Tarbolton, Ayrshire. Aged 57 years.

On the 9th of January, 1884, Mr. Charles Marshall, Pharmaceutical Chemist, London Road, Reigate. Aged 40 years.

On the 10th of January, Mr. George Alfred Lockwood, Chemist and Druggist, South Street, Moor, Sheffield. Aged 52 years.

On the 15th of January, Mr. William Walton, Pharmaceutical Chemist, City Road, Old Trafford, Manchester. Aged 42 years.

On the 16th of January, Mr. Herbert Joseph Abington, Chemist and Druggist, High Street, Ringstead. Aged 75 years. Mr. Abington had been a Member of the Pharmaceutical Society since 1873.

On the 20th of January, Mr. James C. Larkworthy, Chemist and Druggist, Spring Grove, Isleworth. Aged 82 years.

On the 20th of January, Mr. Richard Reckerby Sheppard, Chemist and Druggist, South Road, Sheffield. Aged 57 years. Mr. Sheppard became a Member of the Pharmaceutical Society in 1882.

On the 21st of January, Mr. John Brown, Chemist and Druggist, Eccles, Lancs. Aged 62 years.

On the 21st of January, Mr. Albert Hounsell Biggs, Chemist and Druggist, Pimlico Road, S.W. Aged 46 years.

On the 25th of January, Mr. George Hayward, Chemist and Druggist, Croydon. Aged 36 years. Mr. Hayward had been an Associate of the Pharmaceutical Society since 1870.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Pharmaceutical Society.

Sir,—I hardly like to confess it, but I am beginning to be a little bit ashamed of owning any connection with such a milk and water affair as the Pharmaceutical Society is getting to be. I have been asked sometimes what good has the Society done for the chemists and druggists, and upon my word I have found it difficult to reply, but it seems to me the answer will soon be easy enough and short,—"None."

There is a great talk about the advancement of pharmacy and the benefit of the public; but when the interests of the trade or the privileges of its members are concerned, or putting in force the Sale of Poisons Act against illegal traders in a large way, why then we do not hear quite so much.

If a twopenny-halfpenny shopkeeper sells a few pennyworths of precipitate, or a poor beggar with a wife and three or four children, struggling for a living and trying his hardest to pass his exam., keeps a shop to enable him to exist in the meantime, he gets a letter from the Society's lawyer with a demand on him for £5. But if a man in a big shop sells cyanide of potassium by the pound to all comers he is not interfered with; or if one of the stores sells chloroform without a poison label, we are told that being a "limited company" they are outside the provisions of the Act," and consequently no action is taken in either case, simply because the parties can fight. Or if a coroner acts in an insulting and threatening manner towards a pharmacist,—instead of taking it up and telling the man that the Society will stand by him and defend his rights, the lawyer points out to the coroner the clause giving exemption, and we have a sort of thankful note in the Journal "that there is reason to hope that the threatened contingency will not arise," with a kind of half-apology for our claiming exemption at all.

I am altogether disgusted that the Council do not speak out firmly on this and other subjects; if they did so they would be much more likely to have the support of the trade, and to be respected by the outside public, both official and non-official, and to be listened to with attention, both in the matter of the Pharmacopœia and the Pharmacy Act amendment, than they are now when they go cap in hand to the Government and the doctors, asking as a favour what they ought to demand as a right.

I do not suppose you will print this in the Journal, I only wish you would, for I know many would agree with me.

Cheetham Hill. W. WILKINSON.

[*** The strength of a chain is measured by its weakest link, and the foregoing letter may serve to illustrate one of the influences which tend to minimize the efficiency of the Pharmaceutical Society as a representative body. We publish it, however, less for the sake of obliging the writer than because we are convinced he would not in his present state of mind regard its suppression as a kindness.—ED. PH. JOURN.]

THE SUPPLY OF PRUSSIC ACID.

Sir,—In the *Pharmaceutical Journal* of February 2, "N. B." finds fault with chemists for selling prussic acid to customers other than medical men. I do not agree with his views. Hundreds of drugs that are in daily demand are poisonous, and if a person contemplating suicide can not procure prussic acid, it is perfectly easy for him to get other poisons, such as laudanum, chlorodyne, strychnine, vermin killers, oxalic acid, carbolic acid, vitriol, etc., which are the drugs more usually resorted to for committing suicide. Of course we can caution purchasers as to their poisonous nature; but if they insist on having them, and that for likely purposes, and promise to use them with caution, we cannot refuse to supply them. "N. B." might as well argue that cutlers should not sell razors or knives lest they be used for murderous purposes, or even ropes, for many have followed the example of Judas and hanged themselves with halters.

Further, prussic acid is frequently used for toilet purposes. If we refer to the query columns of ladies' journals we find that it is often recommended for whitening or bleaching the skin; cyanide of potassium is also mentioned for the same purpose. Prussic acid is often required for poisoning dogs, cats, and other animals. I have sold many a half ounce of it for this purpose.

SAMUEL LAWRENCE.

Sir,—The repeated cases of poisoning through carelessness on the part of chemists and druggists in the supply of poisons to the public especially such articles as "prussic acid," induces me to ask you to add my letter to that of "N. B.," as a protest against its sale.

We all know that it is quite legal for any registered person to sell the article in question, provided the necessary signatures are obtained; but, nevertheless, it does seem to me a most unwise (I may say penny wise and pound foolish) policy to supply it to any other person than a medical man, even for the purpose of poisoning dogs.

A case under my notice will illustrate the danger fully. A few days since, a gentleman, entirely unconnected with the trade or medical profession, told me that he had in his possession an ounce bottle filled with Scheele's acid, describing it accurately to me, which he had procured from a druggist, two months ago, for the express purpose of *then* destroying his cat. It is needless to say, the cat is still alive and the poison ready at hand "if required for an insane purpose."

In my apprenticeship, I was taught never to sell the article, but to offer to poison the animal myself, if animal it was required for. I always considered this a very wise policy, and certainly it brings just as much remuneration, if not more. If all druggists would adopt this simple practice we should hear of many less cases of poisoning by prussic acid.

Mr. Morris, of Lowesmoor, could have hardly thought much of what he was doing, when he sold the fatal acid to his customer for the purpose of "cleaning clothes." The poor excuse for its purchase ought to have been apparent at once! I must repeat "N. B.'s" words—"Signing the poisons sale-book will not prevent suicide."

The supply of prussic acid to the public is, therefore, extremely injudicious. Its use is principally for the purpose of taking life, and if druggists allow its sale so readily, Government should interfere and prohibit its sale entirely, for the sake of the community.

228, *South Lambeth Road.* A. E. BERTIE SMITH.

THE PRELIMINARY EXAMINATION.

Sir,—I looked with some curiosity for the result of the new arrangement for the Preliminary examination, and was, I must confess, considerably surprised to see Mr. Hodgson's note expressing satisfaction with the result. It may be satisfactory to the examiner, but I doubt whether the candidates themselves share the feeling. On referring to the Journals of last year I find an average of 13½ questions set at each exam., *i.e.*, Latin, 4¼, Arithmetic, 5, English, 4¼; but last month, under the new rule, 19 questions were set, of these 5 were Latin, 7 Arithmetic, 7 English.

Last year an average of 50⅐ passed, and 49⁶⁄₇ failed. Last month 45⅝ passed and 54⅜ failed. Now, although the candidates were allowed an extra hour and half they had 5½ more questions to answer, and of these two were in arithmetic, the subject that has always caused most failures.

I was under the impression that the extension of time was solely to prevent the candidates being hurried, but the above data would point to raising the standard for the Preliminary exam.

I trouble you with this note in order to point out to intending candidates that they must look out for extra work as well as extra time.

L. S.

"*Student*."—(1) Beale's 'How to Work with the Microscope' (Harrisons) or Carpenter's 'The Microscope' (Churchills). (2) An acquaintance with the language is required, not with any special book. (3) The preparation to which you refer is now so well known by the name commonly applied to it, that the use of the name, though incorrect, is to a certain extent justifiable. With those who object to the misnomer it is a common practice to attach to it a qualifying indication. (4) Yes, for the present.

J. R. Hill.—Copies of the Return may be obtained from Messrs. Hansard, Great Queen Street, London, W.C.

"*Doubtful*" is referred to the rule as to anonymous correspondents and to a Latin grammar.

"*Minor*" is recommended to consult the advertisement pages, as we cannot undertake to recommend particular tradesmen.

H. C.—The answer would depend upon the composition of the ink, of which you say nothing.

E. V. Z.—Probably indigo would be the best dyeing material. See the article on Dyeing in Ure's 'Dictionary' or Crace-Calvert's work on the subject.

"*Student*" (Christchurch).—(1) Dissolve the hyd. perchlor. in the spirit, add the ether and then the boracic acid in fine powder. Solution will not take place, so the bottle must be shaken before use. (2) Use carbolic acid in crystals. If the mass be dry, use as an excipient glycerine of tragacanth; if moist, powdered tragacanth. (3) Dissolve the phosphorus in benzol; powder the strychnine with the ferrum redact., and add the zinc. valer. As an excipient use glycerine of tragacanth. (4) Dissolve the salicin in a little aq. chloroformi; powder the quinine and add a little mucilage to suspend it, and mix with the other ingredients.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. T. and H. Smith, Bowie, Combs, Wilkinson, Newsholme, Nicholson.

"THE MONTH."

It is extraordinary that, notwithstanding, the electric light has now found wide application for a considerable time, so litle unimpeachable information is available as regards its cost as compared with that of gas. One of the most useful contributions upon the subject was a letter sent to the *Times* at the beginning of last year by Mr. O. E. Coope (*Pharm. Journ.*, [3], xiii., 602), in which he gave his experience in lighting Berechurch Hall by electricity with Swan incandescent lamps during the few preceding months. This he has now supplemented by a second letter (*Times*, Jan. 29) giving his experience for another twelve months. He reports that during the whole of this time there has been no mishap of any kind, with the exception of the belt slipping three times, which caused five minutes' delay at the outside. The lights have been found steadier than gas, and the lamps instead of being 18-candle power, as when started, are now working up to 20-candle power. There are two hundred of these lamps in use and the renewals numbered three hundred during the twelve months, in which the actual working hours of the lights amounted to 1823. The expenditure, including 10 per cent. of cost for depreciation of machinery and 5 per cent. for depreciation of conductors, amounted to £232 15*s.* 1*d.*, or nearly one farthing (0·9 of a farthing), per 18-candle lamp per hour. Mr. Coope says that another year's experience enables him to reassert most emphatically what he said last year as to the advantages of the incandescent lamp. He recommends that the plan of massing the lamps in electroliers should not be adopted in lighting dwelling houses, but that the lamps should be rather kept as far as possible apart. A Mr. Bower, writing to the *Times* subsequently, gives data to show that the same amount of effective light could have been obtained by burning coal gas, estimated to have been produced for 3*s.* 5*d.* per 1000 cubic feet, at a cost of one-sixth of a penny per light per hour.

Under the rather questionable caption of "Sound Mills," which recalls to the memory some of the fabulous rumours that got abroad when Mr. Crookes first described the radiometer, Professor Silvanus Thompson has given an interesting account (*Nature*, Feb. 13) of some apparatus designed by Dr. Dvorák to demonstrate the influence of sound waves in a manner analogous to that in which the radiometer marks the effect of light waves. One of these "sound mills" consists of four light hollow spherical glass resonators, suspended from the extremities of the arms of a light wooden cross, balanced on a needle point; the balls, which are 4·4 cms. in diameter, have each a slightly protuberant opening of 0·4 cm., all the openings being turned to follow in the same direction. The resonators respond to the note *g*′, and when that note is forcibly sounded by an appropriate tuning fork the air in the resonators vibrates in response, and the apparatus begins to rotate. Briefly the explanation of this action is that at all nodal points in the vibrations of the air in tubes or resonant boxes the pressure of the air is greater than elsewhere, and therefore any resonator closed at one side and open at the other is urged along bodily by the slight excess of pressure on the closed end. There are four kinds of "sound mills" described and figured in the paper.

Sir James Paget, whose interesting papers on abnormal growth of plants attracted so much notice some time since, has drawn attention in the *Medical Times* (Feb. 16, p. 206) to some remarkable investigations made by Dr. Beijerinck in connection with the formation of gum in trees, lately published by the Royal Academy of Sciences at Amsterdam. Dr. Beijerinck found that in the peach, apricot, plum, cherry, or other trees bearing stone fruits, the formation of gum may be caused by inserting a portion of the gum under the edge of a wound through the bark. The observation that heated or long-boiled pieces of gum would not produce this effect, and that wounds made in the bark of the tree did not produce gum unless a portion was first introduced into it, led him to suspect that the formation of gum was due to the presence of bacteria or other living organisms. On microscopical investigation he found that only those pieces of gum containing spores of a highly organized fungus, belonging to the *Ascomycetes*, had the power of conveying the gum disease or gummosis, and that these spores, inserted by themselves under the bark, produced the same pathological changes as did the pieces of gum. The fungus has been examined by Professor Oudemans, who has ascertained it to be a new species, and has named it *Coryneum Beijerinckii.* Its chief characters consist in the fact that it has a cushion-like stroma, composed of a bright brown parenchyma, on which stand numerous conidia having colourless, unicellular and very slender stems, about as long as themselves. The conidia are small, cask shaped, about one-thirtieth of a millimetre in length, and usually divided by slightly constricting septa into four cells, of which the two terminal are longer than the two middle ones. From these cells germinal filaments may proceed, from which are developed yeast-(like?) cells, or brown thick-walled and many-celled mycelia. The first symptom of the gum disease is the development of a beautiful red colour around the wound due to the formation of a red pigment in one or more of the layers of the cells of the bark. Dr. Beijerinck believes that the fungus produces a fluid of the nature of a ferment, which penetrates the adjacent structures, since the disease extends beyond the parts in which any trace of the fungus can be detected. This ferment he believes to act on the cell walls, starch granules and other constituents of the cells, transforming them into gum and even changing into gum the *Coryneum* itself. The influence of this fluid is also exerted in the cambium, causing the formation of morbid parenchyma, the cells being cubical or polyhedral, thin-walled and rich in protoplasm that is in its turn transformed into gum. It is further stated that "a similar disease produces gum arabic, gum tragacanth, and probably many resins and gum resins." Gum tragacanth is known to be produced by the pith as well as the bark of the stem, and to ooze out from the pith when the stem is cut, and if it be indeed due to a disease it would seem as if the disease infects the whole plant. Gum, moreover, may be found in the uninjured husk of the almond, and it seems at first sight more probable that the irritation caused by a fungoid parasite should cause a greater flow of the natural product, just as the irritation caused by an insect causes the development of galls. Whether this be so or not, the discovery that it is possible to produce artificially a free flow of gum is a valuable discovery, since it may now be found advantageous to cultivate certain trees for the purpose. This is a point which might well attract the attention of the Forestry Department, since the importations of gum arabic at the present time consist largely of a variety that gives a ropy, slightly adhesive and very unsatisfactory mucilage.

In *Nature* (January 31, p. 313) Dr. G. Schweinfurth gives an account of some new botanical discoveries made by him in connection with the mummies of the twenty-first Egyptian dynasty, found at Deri-el-Bahan. In the floral wreath on the mummy of the Princess Ugi-Khouni were found folded leaves of a willow, *Salix Safsaf*, perfect flowers of the corn poppy (*Papaver Rhœas*, var. *genuina*), flowerheads of *Centaurea depressa*, and of *Picris coronopifolia*. The flowers of *P. Rhœas* appear to have been gathered in an unopened condition to prevent the petals from falling, and are in such good condition that Dr. Schweinfurth remarks that such perfect and well-preserved specimens of this fragile flower are rarely to be met with in herbaria. It is worthy of note, too, that the character of this variety of the poppy, var. *genuina*, although gathered more than three thousand years ago, are identical with those of the same variety known at the present day. With respect to *Picris coronopifolia* the author remarks that not a single peculiarity is apparent by which it might be distinguished from the recent small form with low spreading branches now so common on the outskirts of the desert. From the occurrence of this flower in the wreaths it is possible to conjecture that the burial of the princess took place in March or April, since there would have been considerable difficulty in obtaining the flowers after the latter month. It has also been determined by capsules of the linseed plant found in a Theban tomb of the twelfth dynasty, 2200–2400 B.C., that the flax used by the ancient Egyptians was derived from *Linum humile*, Mill., and that the mustard oil used by them was derived from one of the two varieties of *Sinapis arvensis*, viz., *S. Allionii*, Jacq., or *S. turgida*, Del., both of which are still common in Egypt.

In the *Journal of Botany* for February, Mr. W. Carruthers, F.R.S., points out that the grass, *Anthoxanthum Puellii*, Lee and Lam., which has within the last few years been met with in Britain and was supposed to have been an indigenous plant hitherto overlooked, occurs only in localities which are not free from the suspicion that the plant has been introduced with agricultural seeds. This opinion receives some weight from the fact that the seed of this grass is being increasingly used by seedsmen to adulterate that of *A. odoratum*. The seed of *A. Puellii* differ from that of *A. odoratum* in being enclosed in straight paleæ, entirely covering the seed, and having hairs arranged in lines along the midrib and veins along the edges, and two or three irregular teeth at the apex. The seeds also are of a paler colour than in *A. odoratum*. In the latter the two paleæ are arched, so as to allow a portion of the seed to be seen between the open edges, are everywhere clothed with hairs, and are rounded at the apex, not toothed.

The means by which the function of aeration, usually performed by lenticels, is carried on in those climbing shrubs in which they are absent, has been recently investigated by Herr Klebahn, who finds that, in all cases which he has examined, there are a number of parallel cellular interspaces extending through the cortex, cambium, wood and medullary rays, and are thus in connection with the interspaces of the wood, forming a very eficient system of aeration for the stem.

In the leaves of *Abies pectinata* Herr Wilhelm has found a peculiar structure of the stomata, apparently intended to hinder transpiration. These openings contain a number of nearly black patches, composed of a great quantity of minute granules of the nature of wax, apparently identical with that which covers the surface of the leaves. They are present in the stomata at all times of the year.

The root hairs of plants have formed the subject of an exhaustive study by F. Schwarz, with regard to the morphological and physiological relations. He finds that the increase of absorptive surface presented by the presence of these hairs as compared with that of naked roots is from 5·5 to 18·7. Their development is interfered with either by too much or by too little moisture; too little causing a local increase, and too much causing a general decrease in the amount of root hairs formed. In some experiments made by J. Vesque on the oleander and garden bean, it was found that the absorption of water by the roots of these plants increased in the case of the former in proportion to the atmospheric pressure, osmose not always appearing to be very active, since when the atmospheric pressure was reduced to about 60 c.m. of water, absorption was arrested.

Observations made by V. Marcona on the movements of the sap in plants in the tropics indicated that in the plants examined, viz., *Carica Papaya* and a liana, there are two periods of maximum rapidity in the twenty-four hours, one between 8 and 10.15 a.m., and the other between 1 and 3 p.m., the rapidity in the latter being less than in the former and sinking gradually to zero, the activity commencing again after sunrise.

W. Detmer regards the organic acids as being the chief promoters of osmose, and consequently of the turgidity of the cell; the conversion of starch into sugar being also largely dependent on the presence or absence of free acids, small quantities of hydrochloric, nitric, phosphoric, acetic and oxalic acid promoting this conversion in a remarkable manner. He has also found that no transforming ferment can be formed in the cells of higher plants in the absence of oxygen. This fact may throw some light on the formation of gum more readily where trees are wounded.

The commercial samples of liquid starch sugar, or "glucose," examined by the Committee appointed in the United States to investigate the subject of starch sugar, to which reference was made recently, were found to contain from 34·3 to 42·8 per cent. of dextrose, 0 to 19·3 per cent. of maltose, 29·8 to 45·3 per cent. of dextrin, and 14·2 to 22·6 per cent. of water. The samples in the solid form—"grape sugar"—ranged in composition from 72 to 73·4 per cent. of dextrose, 0 to 36 per cent. of maltose, 4·2 to 9·1 per cent. of dextrin, and 14 to 17·6 per cent. of water. Three specially prepared samples of "grape sugar" contained respectively 87·1, 93·2 and 99·4 per cent. of dextrose, the last being "crystalline anhydrous dextrose." The ash in the "glucoses" varied between 0·325 and 1 per cent., and in the "grape sugars" between 0·335 to 0·75 per cent. The reporters add that in the United States starch sugar is chiefly used in making table syrup and artificial honey, in brewing and vinegar making, as well as in the adulteration of cane sugar and as a substitute for it in confectionery and canning fruits. It is estimated by the Committee that the industry in the United States gives employment to twenty-nine factories, which together represent a capital of one million sterling, consume about forty thousand bushels of maize daily, and produce "glucose" and "grape sugar" to the value annually of two million pounds.

At the Pharmaceutical Meeting in Philadelphia on January 15, Professor Maisch exhibited a root called cinnamon root, which was said to be used in Europe for the purpose of adulterating powdered cinnamon. The root had a flavour of cinnamon and cloves. Dr. A. W. Miller stated that in the neighbouring city of Camden there was a factory for roasting and grinding cocoa nut shells, the powder of which was used for adulterating spices; it sells at $2\frac{1}{2}$ cents per lb., and enables the fraudulent operator to dilute the spice and obtain large profits (*Amer. Journ. Pharm.*, Feb., p. 124).

Hyoscine, the second henbane alkaloid, which about three years since (*Pharm. Journ.*, [3], xi., 351) was isolated by Herr Ladenburg from residues from the preparation of hyoscyamine, has been further investigated by the same chemist (*Berichte*, xvii., 151). He has confirmed his previous experiment that when hyoscine is treated with alkalies it splits up, like atropine, into an acid and a base, the acid being identical with tropic acid, but the base being only isomeric with tropine (pseudotropine). The identity of the acid was proved by combining it with tropine, under the influence of hydrochloric acid, to form atropine. All attempts however to regenerate hyoscine by recombining the tropic acid and pseudotropine were without result. Pseudotropine is described as crystallizing in rhombohedra, and being less hygroscopic than tropine, but soluble, like it, readily in water and chloroform and less freely in ether. It melts at 106° C., and boils between 241° and 243°. By treatment with hydrochloric or sulphuric acid a new base can be obtained from pseudotropine, which is isomeric with tropidine.

"Belladonnine" is another little-known solanaceous alkaloidal substance that has been investigated by Herr Ladenburg. The name was originally given by Herr Hubschmann to a basic substance noticed in belladonna root, and the subject was afterwards investigated by Herr Kraut, who left the decision as to its composition unsettled. The question has therefore been taken up by Herr Ladenburg (*Berichte*, xvii., 152), working upon material supplied by Messrs. Gehe. This consisted of a brown, viscous, semi-solid mass, obtained from the mother liquor of atropine sulphate, and agreed in its characters with the substance examined by Herr Kraut. It was only slightly attacked when heated with baryta, but went completly into solution when boiled with alkalies. The alkaline solution gave up to chloroform or ether a basic mixture, one part of which consisted of tropine, and the other of a strong base which was at first thought to resemble pseudotropine, but which on analysis was found to be oxytropine. The acid products of the decomposition proved to be tropic acid and its derivatives, atropic and isatropic acids. It is therefore thought probable that the substance used in the investigation was a mixture of atropine with oxyatropine. Herr Ladenburg proposes to revert to the subject of belladonnine in a future paper.

Another interesting step towards effecting the complete synthesis of alkaloids has been taken by Herr Ladenburg in the conversion of pyridine into piperidine (*Berichte*, xvii., 156). The reverse operation, the conversion of piperidine into pyridine, had already been effected by Professor A. W. Hofmann and others, whilst Herr Ladenburg had obtained a similar result with tropidine (*Pharm. Journ.* [3], xii., 1049). Herr Ladenburg had therefore proposed to work upwards from pyridine, through piperidine, to hyoscyamine, but hitherto all attempts to hydrogenate pyridine by the usual agents had failed. This has now, however, been accomplished and piperidine has been obtained by the action of sodium upon an alcoholic solution of pyridine. It is also hoped that homologues of piperidine may be obtained by similar treatment of the other tar bases.

Reference has already been made in these columns to the divergent opinions expressed by different investigators with respect to the nature of picrotoxin (*Pharm. Journ.*, [3], xi., 352, 897). It will be remembered that, according to Messrs. Barth and Kretschy, ordinary picrotoxin would consist of a mixture of three distinct bodies, separable by fractional crystallization from benzol and water, which they proposed to call "picrotoxin," "picrotin," and "anamirtin," and that Messrs. Schmidt and Löwenhardt considered two of these bodies at least to be products of decomposition resulting from the action of the hot solvent. Herr Schmidt has now published (*Annalen*, ccxxii., 313) the results of a further investigation which are quite confirmatory as to the homogeneity of picrotoxin. Samples prepared by himself, and others obtained commercially and purified by repeated recrystallization from strong alcohol and water, were found to consist of colourless stellate crystals, having uniformly a composition represented by the formula $C_{30}H_{34}O_{13}$ and a constant melting point of 199–200° C. This product was, however, easily decomposed by hot benzol, or even by chloroform at the ordinary temperature, into two other bodies which he calls "picrotoxinin" and "picrotin." The melting point of a mixture of these bodies is, however, not uniform, since although it commences to fuse at 200° C., it does not completely melt before 210° to 230° C. The decomposition is represented by the equation:—

$$\underset{\text{Picrotoxin.}}{C_{30}H_{34}O_{13}} = \underset{\text{Picrotoxinin.}}{C_{15}H_{16}O_6} + \underset{\text{Picrotin.}}{C_{15}H_{18}O_7}$$

Picrotoxinin melts at 201° C., is bitter and poisonous; whilst picrotin melts at 255°–256° C., and is bitter and non-poisonous.

The well-known red coloration of carbolic acid has been the subject of a number of theories and assertions, but none put forward yet has enabled the manufacturers to overcome the difficulty, which frequently involves them in considerable loss. The *Pharmaceutische Post* (Feb. 2 and 6, pp. 101 and 131), contains an account of the results of a large number of experiments, which, as they promise to be of some practical use, may be briefly summarized. It was found that English crystallized crude carbolic acid contained certain volatile and colourless substances, which under the influence of light, and to a less degree of warmth and air, were converted into red and yellow-brown non-volatile compounds, and that of these compounds that which afterwards became red passed over in distillation with the first portion of the carbolic acid, and that which became yellow-brown with the last. In a fractional crystallization these colour-yielding compounds did not form part of the carbolic acid crystals, except to the extent that they were enclosed mechanically, but were concentrated in the mother liquor. They were only slightly soluble in cold water, and insoluble in benzin, but could be readily extracted from a solution by means of water acidulated with sulphuric or phosphoric acid. Contact with oxidizing agents during the distillation appeared to affect the compounds only partially. But in aqueous solution in the presence of free sulphuric acid oxidizing agents attacked both the colour-yielding compounds; the resulting oxidation products appeared to be more easily soluble in water than the original substances, whilst they had lost their volatility or passed over in small quantity only with the last portions of the acid. Referring to the theory that the colour is attributable to lead derived from the glass vessels used in the distillation of the acid, it is stated that no metal could be detected even in strongly coloured glass-distilled samples of carbolic acid.

The unpleasant consequences that sometimes follow the inhalation of an atmosphere charged with emanations from freshly painted surfaces are well recognized. The *Lancet* (Feb. 16, p. 313) appears to be disposed to attribute these to the action of some volatile compound of lead, notwithstanding that lead compounds are supposed to be non-volatile, and that the inconveniences are by no means confined to lead paints. The observation, however, upon which the *Lancet* bases this conclusion is sufficiently curious to be worth further investigation, it being to the effect that luminous paint, the basis of which is calcium sulphide, when unprotected is found to be perceptibly blackened by the fumes from fresh lead paint in its vicinity.

An interesting note upon the preparation of ferric ethylate and the separation from it of a colloidal ferric hydrate has been forwarded to the French Academy by M. Grimaux (*Comptes Rendus*, xcviii., 105). He states that when a molecule of ferric chloride dissolved in absolute alcohol is allowed to react upon six molecules of sodium ethylate, there is an immediate precipitation of sodium chloride, leaving a clear very dark brown solution that no longer contains chlorine, but in which the iron is present in the state of ferric ethylate. A solution made with 3·25 grams of ferric chloride dissolved in 25 c.c. of absolute alcohol and 1·40 grams of sodium dissolved in the same weight of alcohol can be distilled in a water-bath without alteration, and leaves as a residue a black pasty mass, soluble in absolute alcohol, benzine, chloroform, ether, petroleum and methylic alcohol. But if this residue be heated in a vacuum so as to remove all traces of the solvent there is a separation of a brown powder consisting of ferric hydrate; the small quantity of water that may be present in the alcohol or that may have been acquired during the manipulation reacting upon the ferric ethylate and decomposing it almost entirely. When the alcoholic solution is exposed to the air it absorbs moisture rapidly and the ferric hydrate separates as a thick coagulum. When the solution is thrown into excess of water a clear liquid is obtained, presenting the characters of solutions of colloidal hydrate of iron described by Graham, but which coagulates spontaneously after a longer or shorter time. The coagulation takes place more rapidly the smaller the quantity of water, and is also promoted by heat. The coagulum of ferric hydrate forms a thick jelly, at first transparent and retaining by capillary affinity so much water that even in dilute solutions it occupies the entire bulk. But gradually in the cold, and more rapidly when heated, the jelly contracts, the water separating and forming a kind of supernatant serum, the phenomena resembling in many respects those observed in the coagulation of blood.

The alteration in the blood caused by the administration of nitrite of sodium has recently been the object of spectroscopic investigation by M. Hénocque, who has made known his results to the Société de Biologie (*Medical Times*, Feb. 9, p. 197). He finds that under the influence of this drug hæmoglobin temporarily loses its power of absorbing oxygen and becoming converted into oxyhæmoglobin. He considers the action to resemble the asphyxia caused by carbonic acid rather than that resulting from carbonic oxide, since the effect gradually passes off and the corpuscles ultimately regain their normal functions.

Dr. T. M. Dolan, in the *British Medical Journal* (Feb. 9, p. 261), recommends sulphide of calcium in solution as a satisfactory lotion in scabies, and much superior to sulphur ointment, it being more easy of application, cleanly and speedy in its action. The mode of application is to give a warm bath, paint the patient's body with the lotion, and when the itching has ceased give another warm bath. The lotion is made by boiling together flowers of sulphur, 100 parts; quicklime, 200 parts; water, 1000 parts. The clear solution is preserved in hermetically-sealed bottles.

Paraldehyde does not appear to be received with much favour at the present time. Dr. J. C. Wilson, in the *Maryland Medical Journal*, states that he has employed it in nine cases; but that several patients complained of the disagreeable after-taste. On account of its unpleasant taste and odour it requires to be given with a considerable quantity of water. In his opinion it may form a useful addition to the ordinary hypnotics, but is not likely to supersede them. The dose he has given is one fluid drachm, but this quantity soon ceases to produce its effect and the dose soon requires to be increased (*Medical Times*, Feb. 9, p. 198).

Dr. R. Shingleton Smith, in a paper in the *British Medical Journal* (Feb. 16, p. 314), confirms the statements made by Dr. Filehne that kairine is a powerful antipyretic, and that it will reduce the temperature in from two to six hours to the normal state with perfect safety to the patient. He considers that the quickness of its action gives it a great advantage over quinine, the only disadvantage attending its use being that its effects are more evanescent than those of quinine. Dr. Smith considers that kairine is a valuable drug, which will perform quite safely, quickly, and pleasantly the office which has hitherto been effected by nothing else than the disagreeable and troublesome cold bath. Further observations recorded in the *Medical Press* (Feb. 13, p. 143) indicate, however, that kairine is not without certain disadvantages. Dr. Guttman states that patients complain very much of the taste of the drug, so much so, that it had to be given in wafer paper, whilst the course of the disease is not in the least altered by the medicine. Messrs. Colin and Zadek state that in intermittent fever especially, or the malarial form even, large doses did not cut short the attack. According to Dr. Menche, also, collapse sometimes follows its administration in typhus and pneumonia.

Dr. J. B. Mitchell in the *Lancet* (February 9, p. 283) recommends castor oil as a most satisfactory lubricant for use in the insertion of catheters, its viscidity and tenacity causing it to adhere to the instrument where other lubricants would become removed before the bladder is reached. It does not, as might have been supposed, produce any irritation.

An illustration of the saying that "doctors differ" may be found in the pages of the *Medical Press* (Feb. 6, p. 127) under the head of "Is Lobelia a Poison?" Lobelia is generally considered by the medical profeision to be as much a poison as tobacco, when taken internally; yet in the recent trial of a medical botanist, one witness, a M.R.C.S., stated that for thirty years he had been in the daily habit of using and prescribing it, and had himself taken it in doses of 1 drachm. There can be no doubt that the drug is largely used in full doses by the followers of Skelton and Coffin, and yet comparatively few cases of poisoning occur. This is probably due to the fact that it is usually given in conjunction with large doses of cayenne pepper, and the rapid emetic effect which follows administration of the drug in this combination prevents it from being absorbed into the system. That it is a powerful drug and should only be used by those who are well acquainted with the conditions under which it may prove dangerous or fatal, is evident from the narrow escape the late Professor Palmer had from death by a large dose of the drug, although in his case it ultimately cured instead of killing him.

Professor Lustgarten is reported (*Pharm. Post*, Jan. 26, p. 86) to have made some experiments with mercurous tannate, which have shown it to surpass all other mercurial preparations for therapeutic purposes. The dose is one decigram two or three times a day.

Bromine is strongly recommended by Dr. Schiltz (*Pharm. Central.*, Feb. 14, p. 71) in the treatment of diphtheritis. One form in which he uses it is as a solution prepared from aqua chlorata, 30 parts; aqua dest., 150 parts and potass. brom., 3 parts. The bromine separated by the chlorine from the bromide of potassium remains dissolved in an excess of the latter, like iodine in potassium iodide. The standard for aqua chlorata, P.G., is lower than that for chlori liq., B.P., since it is only required to contain "at least" 0·4 per cent. of chlorine as compared with 0·6 per cent.

The physiological effects of jequirity still continue to be a subject of investigation by Messrs. Cornil and Berlioz. In a paper recently read before the Académie de Médecine they state that an injection of 10 to 20 drops of the infusion into the breast of a fowl caused rapid poisoning terminating in death, copious diarrhœa being the most marked symptom. If a small quantity only be injected local œdema and damage to the neighbouring muscle is produced, but immunity is acquired (*Lancet*, February 9, p. 267).

A new micro-organism, *Bacillus beribericus*, has been discovered in the blood of patients suffering from the disease known in the tropics as beri-beri. The organism consists of cylindrical branched filaments, with genuine joints and sometimes refracting brilliant points which are believed to be spores. The filaments cultivated after Pasteur's method and injected into rabbits have caused all the symptoms of beri-beri. M. de Lacerda believes that the parasite is originally derived from rice which has undergone a peculiar alteration (*Lancet*, Feb. 9, p. 268).

Some further particulars as to the results obtained by the Cholera Commission sent out to India by the German Government have been received from Dr. Koch, writing from Calcutta on the 17th ult. The first experience in India was that in dissecting the dead bodies of nine cholera patients, in every case the same bacilli were discovered with the aid of the microscope that were observed by the Commission whilst in Egypt (see before, p. 321). But this left it still undecided whether these bacilli did not belong to the regular parasites of the gut, having made their way into the mucous membrane of the intestine under the influence of the cholera disease. Some of the bacilli were, therefore, isolated from the intestinal contents of the purest cholera cases and cultivated in gelatine, so that their form and growth might be sufficiently studied to allow of their being distinguished from other bacilli. In this way it was demonstrated that this kind of bacillus was present in all the choleraic evacuations examined, as well as in all the intestinal contents from persons who had died of cholera. On the other hand, the bodies of eight persons who had died of pneumonia, dysentery, phthisis and kidney disease have been examined, as well as bodies of several animals and other substances abounding in bacteria, but in none of these cases has anything been found like the cholera bacillus. It is also reported that the same organism has been discovered in water from a tank, which had been suspected of having been a source of the disease.

In connection with this subject reference may be made to the recent important decision of Mr. Justice Pearson, in the case of *Ballard* v. *Tomlinson*, that the owner of a well may use it as a receptacle for sewage, even though in doing so he may contaminate other wells in the same water-bearing stratum. In this particular case the plaintiff was a brewer depending for a supply of water upon a well sunk into the chalk, which had been in use for the same purpose for thirty years. Within one hundred yards is another well, sunk into the same water-bearing stratum, which has of late been used by the defendant as a cess-pit. That both wells have a common source was not denied; indeed this was proved by putting chloride of lithium into the defendant's well and finding it forty-eight hours afterwards in water taken from the plaintiff's well. It was admitted also that in like manner the defendant's sewage made its way into the plaintiff's well, poisoning the water and rendering it entirely unfit for brewing or any other dietetic use. But it was claimed that this was within the defendant's right, both to abstract water from the well and to return it to the well polluted to any extent he pleased, and this claim has been upheld by the Court. The possible effect of this decision upon the public health will be evident, and Dr. Frankland has pointed out in a letter to the *Times* (Feb. 15), that there would appear to be nothing to prevent the establishment of an aniline colour factory in the neighbourhood of the deep wells in the chalk used by the Kent Water Company for the water-supply of a part of the metropolis, and the discharge of its waste arsenical liquors into the subterranean reservoir from which the water is drawn. The inconsistency exists, therefore, that whilst a manufacturer is not allowed to discharge any noxious material into surface water, he may do as he pleases with subterranean water.

REPORT ON ANALYSES OF SPECIMENS OF CINCHONA BARK.

Forwarded from Madras, through Her Majesty's Secretary of State for India, to the Pharmaceutical Society.

(1) This and two following samples are from *C. Condaminea*, How. variety.

(2) These botanical specimens and also the bark were taken from coppice shoots.

(3) The bark belonging to this specimen is renewed, after the tree had been subjected to the Java shaving process. In this the outer cellular portion is shaved or pared off, the inner vascular layer being left intact.

(4) Bark covered externally with a thick corky layer, very peculiar, of officinalis type but undetermined species.

(6) Large leafed or *C. Uritusinga*, Pavon type.

(7) This is the No. 2 variety, in the estate nomenclature, of the variety *C. angustifolia*, How.

(14) This species was discovered by Hasskarl, cultivated on a large scale in Java and found to be worthless. From Java it was introduced into India, where its culture never went beyond the stage of an experiment.

(17) This plant was said by Cross, on his recent visit to the Nilghiris, to be the *C. crispa* of which he sent seeds from the Loxa Mountains. That it came from Loxa there is no doubt, as the few specimens of it on the estate of Dodabetta are growing amongst the "crown" barks introduced from that region. It differs, however, very much from the *C. crispa* of Tafalla, which belongs to the *C. officinalis* group of Weddell. In general appearance it is more nearly allied to Weddell's section *Pahudianæ*. Its bark is also very peculiar, in fact unique.

(20) This form of the *C. Calisaya* grows to a considerable size and has bright green shining leaves, some of which measure from 6 to 7 inches in length by 3½ to 4 inches in width. Flowers pink, very sweetly scented.

(21) This plant approaches the *Boliviana* form of Weddell, but the *Calisayas* are most variable.

(23) This plant, according to Howard, is a hybrid between *C. Calisaya* and *C. succirubra*. On the other hand it is said to come perfectly true from seed. Mr. Surgeon-Major Bidie thinks it to be only a variety of *C. Calisaya*.

(26) This is not the *C. pubescens* of Vahl, but a plant which was considered to be a hybrid by the superintendent of the cinchona estates, the late Mr. McIvor. Mr. Cross regards it as the pubescent form of "Cuchicara," referred to by Dr. Spruce in the Parliamentary Blue Book of 1863, p. 116. Mr. McIvor stated that it is a hybrid between *Cinchona succirubra* and *Cinchona officinalis*.

(29) Pata de gallinazo of Cross.

When the valuable series of specimens of Madras cinchona bark was presented to the Museum of the Pharmaceutical Society by the Indian Government, through Dr. Bidie, it appeared to be important that analyses should be made, in order that the specimens might be rendered thereby more useful for reference, and that the analyses might be available for comparison with others which might be made subsequently on the plantations. Therefore having learnt from Mr. Holmes, the Curator of the Society's Museum, that portions could be spared from the Museum specimens without destroying their value for reference I undertook to carry out the examination. Unfortunately, the smallness of some of the samples precluded the possibility of dividing them. Only eleven specimens, however, out of the forty-nine received were too small to be divided. The preceding table gives the results obtained. The footnotes are taken from remarks written on the Herbarium specimens by Dr. Bidie. The specimens No. 39 to 43, marked "India," are barks which were forwarded last year from Darjeeling by Dr. King.

These specimens of bark illustrate very well the influence of hybridization in masking the characteristic features of the bark of particular species of *Cinchona*, and the difficulty of forming an opinion as to the source of samples as well as their value in regard to amount of alkaloid.

I learn from Mr. Holmes that a comparison of the samples of *C. officinalis* bark indicates that the only one which could be easily recognized is No. 4. In this sample the bark presents an extraordinary development of the suberous or corky layer, which is divided into angular pieces about half an inch square, each piece exhibiting a stratified appearance. It is totally different from Nos. 17 and 18, in which the suberous layer, although very much developed, presents a rough granular appearance more like toasted bread-crumbs and is very friable. The corky *C. officinalis* also possesses more quinidine (0·45) than the other varieties, and a good percentage (4·08) of quinine. No. 4 is evidently the bark referred to by Dr. Trimen in his report "On the Nilgiri Plantations," as being the "crispa" of McIvor and Beddome, of which a vigorous propagation was going on by seed. If it can be shown, therefore, by further analyses on the plantations that these percentages are tolerably constant, this variety would appear in every way to be specially suited for pharmacy.

On examination of the several specimens of renewed bark of *C. officinalis*, Mr. Holmes is of opinion that it would not be possible to recognize by physical characters bark rich in alkaloids from a poor one, and that however valuable such bark may be to the quinine manufacturer it would not be expedient for pharmaceutical use, unless a guarantee as to alkaloidal strength were supplied to the retail pharmacist. It is also of interest to note that in Nos. 2, 6 and 8 the smaller amount of quinine found by analysis is associated with an increased amount of cinchonidine. The fact that No. 2 was obtained from coppice shoots adds weight to the supposition that the age of the tree may have something to do with the yield of cinchonidine; while the fact that the renewed (No. 6) and the natural (No. 8) *Uritusinga* varieties yield less quinine than the *angustifolia* and *Condaminea* points to the latter as being the better varieties, *i.e.*, so far at least as can be gathered from a limited number of analyses.

The bark of *C. Pahudiana* might easily be mistaken by an unpractised eye for that of *C. officinalis*, and it seems desirable that such an inferior bark should be eliminated from the plantations as speedily as possible, lest by cross-fertilization it should deteriorate the seed of more valuable species. The same remark applies to the corky barks, Nos. 17 and 18, which, although very different in appearance from *C. Pahudiana*, are produced by a tree which has on its young shoots and capsules the peculiar coarse hairiness of that species, although in a less degree, forming a feature by which it is easily distinguished.

The specimens of the bark of *C. anglica*, from the Nilghiris, are not easily recognizable by physical characters, and Mr. Holmes considers that they bear evidence of the hybridization of the plants with *C. succirubra*, particularly No. 23, which gives 1·90 of cinchonine. This, he thinks, is further confirmed by the large leaves, resembling in size, shape and venation those of *C. succirubra*. The capsules also more nearly approach in size those of that species, being much larger than those of *C. Calisaya*.

With respect to the barks from Darjeeling, No. 39 to 43, Mr. Holmes is of opinion that the samples, judging from their physical appearance, were evidently collected from several different varieties of each species, and therefore the analyses cannot reveal anything special concerning them.

Judging from its physical characters the Ledger bark, No. 42, is good typical *Calisaya* bark, and does not at all resemble the thick bark with scattered warts which was recognized by Mr. Howard as Ledger bark, and of which samples presented by him exist in the Museum of the Society. Taken in conjunction with the analysis, the characters of the No. 42 bark indicate that it approaches most nearly to the *Boliviana* variety of *Calisaya*.

The Nilghiri *Calisaya*, No. 21, appears to be identical with that of Darjeeling. The herbarium specimen of the latter is marked 2000 feet, an elevation that is hardly high enough to develop the alkaloidal richness of the *Calisaya* to its utmost degree.

In Dr. Trimen's recent report on the cinchonas of the Nilghiris he lays great stress on the importance of analysis as a guide in the selection of plants for cultivation, and he expresses his conviction that in the present state of our knowledge, selection based on analysis is the most promising direction for the improvement of the trees as alkaloid yielders. From this point of view he recommends the isolation of trees with high analysis, together with other precautions to prevent cross fertilization, care in collecting seed, analysis of a selection of the resulting plants and destruction of all that do not reach the standard of their parent. It is by the continuation of this mode of procedure in the cinchona districts of the Madras Presidency that Dr. Trimen considers the interests of the great industry of cinchona growing in India can alone be efficiently promoted.

The attempt to draw deductions from the figures of the analyses now published of a limited number of specimens must, of course, be regarded as subject to correction by results of further examinations of a larger series of similar botanical specimens and barks that may come under future notice; but it may be hoped that the facts brought out by analyses of these specimens may prove of some value to the pharmaceutical public and to the energetic Directors of the plantations in India and elsewhere.

THE USES OF POTASSIUM PERMANGANATE IN ANALYSIS.*

BY ARTHUR G. HADDOCK, A.I.C.

My paper does not contain any novelties but is written with a view of showing what an exceedingly useful reagent the chemist possesses in potassium permanganate. I mean as a standard solution for use volumetrically.

I think every chemist who has technical analyses to make will admit that the system of volumetric determination is of the utmost use and convenience. It may be better to use gravimetric methods in cases were the substance can be precipitated in a definite form, in the pure state, and in a form absolutely insoluble in the menstruum used. But these three conditions, which are essential to the success of the operation, cannot always be obtained, and very often, even when it is possible, the number of operations which have to be gone through is so great, and the time required so long, that it would be a source of great inconvenience to the technical chemist to adopt this system. Both volumetric and gravimetric methods have their place in analysis, and it is sometimes convenient and desirable to adopt one system and sometimes the other.

For instance, if a determination of iron was required in a substance containing that metal or any of its compounds, together with manganese, no one would think of going to the trouble of separating the two, and precipitating and weighing the iron as oxide, but a volumetric agent such as bichromate or permanganate of potassium would be used, which would give the required result in a tithe of the time occupied by the other method, and, probably, with greater accuracy.

Permanganate of potassium is one of the most useful solutions which can be placed in a laboratory. The diversity of substances which can be tested with it, the simplicity of its application, and the accuracy of the results which are obtained, entitle it to a very prominent position in the analyst's cupboard.

The crystals may be obtained in commerce in an exceedingly pure form. We have some in the laboratory now, which were bought in the ordinary way, which are practically free from impurity. To try to make the salt on a small scale in the laboratory is both expensive and unsatisfactory, as it is very difficult to get it to crystallize nicely. However obtained, its purity should not be taken for granted, but after making the solution, its strength should be tested. For general purposes, perhaps, decinormal is the most convenient strength to make the solution. This would be obtained by dissolving 31·6 grains of the pure crystals in 10,000 grains of distilled water. It is better to dissolve a little more than the theoretical quantity, as it is very easy to dilute it to the proper strength after standardizing. The solution thus obtained may be standardized in several ways.

One is, by seeing how much FeO it will convert into Fe_2O_3. The purest soft iron wire is used for this purpose. About 2 grains is accurately weighed out and dissolved in dilute sulphuric acid in a flask fitted with a reducing cork to exclude the air, diluted with about 3000 grains cold water, and the permanganate solution run in without loss of time from a graduated burette. The operation is finished when the colour is no longer discharged, but a slight pink shade remains in the liquid. If the solution is decinormal it should require 357 grain measures for 2 grains of iron.

It is difficult to get pure iron wire. Soft binding wire or thin pianoforte, which are about the best, contain from $\frac{1}{4}$ to $\frac{1}{2}$ per cent. impurity, so that it is necessary to test the wire gravimetrically, once for all.

The double ferrous and ammonium sulphate is often recommended for standardizing with. It is stated to be exceedingly stable, and may be kept for months without oxidation. If pure materials are used in making it, and great care is taken in its preparation, this probably is so, but, otherwise, it is not to be depended on. When pure, 7 grains of this salt contain 1 grain of iron. It is dissolved in water, acidulated with dilute sulphuric acid, and the titration effected as with the solution of the iron wire.

I prefer to use oxalic acid to standardize with. It can be obtained very pure and is easily crystallized, so that by recrystallizing the commercial article it can be obtained in a state of absolute purity. 63 grains of the crystals ($H_2C_2O_4 2H_2O$) are equivalent to 31·6 grains permanganate. 3·15 grains may be weighed off and dissolved in about 3000 grains of water, and a little dilute sulphuric acid added. The action in this case only takes place in a hot solution; it must, therefore, be heated to about 70° C. and the permanganate run in as before. The colour is not discharged so quickly as with the iron salt. The solution first goes brown, then yellow, and, finally, colourless. The end-reaction is, however, very distinct, as it is impossible to mistake a brown or yellow shade for the final pink. 3·15 grains would require 500 grain-measures of $\frac{1}{10}$ normal permanganate.

The solution when standardized should be placed in a well-stoppered bottle and kept as much as possible in the dark. It sometimes deposits a little soon after it is made, and is apt to become slightly weaker on that account. After a few months all alteration ceases, and if dust and organic matter is kept out of it, the strength will remain constant for a very long time. I had a solution which, after the first six months, did not vary at all for over two years, and, indeed, very little alteration (2 per cent.) had taken place at the end of five years, and this was a solution I was constantly using. If a deposit forms it should always be restandardized.

With this solution many different determinations may be made. The following are some of the substances which may be estimated by it:—Iron, manganese, lead, calcium, oxalates, ferro- and ferri-cyanides, prussian blue, tannin, methyl alcohol, organic matter in water, etc.

Its equivalents are—

1000 =	3·16	$KMnO_4$
	5·6	Fe.
	6·3	$H_2C_2O_4.2H_2O$.
	2·8	CaO.
	42·2	$K_4FeCy_6.3H_2O$.
	32·9	K_3FeCy_6.
	4·156	Galls tannic acid.
	6·234	Oak bark tannin.
	28·67	Fe_7Cy_{18} (Prussian blue).
	0·80	Oxygen.
	4·53	$MnSO_4$.

Iron.—To estimate the amount of iron in a sample, it is treated in any convenient way to get it into solution in acid, then reduced by means of pure Z_n (preferably amalgamated) to the ferrous state and titrated as before described in the standardizing.

$$10FeSO_4 + K_2Mn_2O_8 + 8H_2SO_4 = K_2SO_4 + 2MnSO_4 + 5Fe_2 3SO_4 + 8H_2O.$$

It is, of course, necessary that all organic matter shall be got rid of. In the case of samples containing only a small quantity of iron, it is desirable to concentrate it by precipitating it as hydrate or phosphate, and dissolving this in a litile acid. It is generally stated that unless a sulphuric acid solution is used the results are incorrect. No doubt, if a great deal of hydrochloric acid is present the results are vitiated to a certain extent, but it has been my experience that if the hydrochloric acid solution is reduced with zinc, and the action allowed to go on till the solution is neutral, and it is after this acidified with sulphuric acid, the results are very concordant and accurate. In iron ores and samples where the iron is in very considerable quantity, I prefer to use bichromate as the oxidizing agent, but in cases where the amount of iron is comparatively small, I think permanganate is preferable.

To estimate the iron in animal charcoal, which contains

* Read at a meeting of the Liverpool Chemists' Association, January 17, 1884.

from ·10 to ·60 per cent., I ignite 50 grains, dissolve in nitric acid, dilute to about 3000 grains, add ammonia in excess, then acetic acid in excess. The acetic acid dissolves the precipitated calcium phosphate, and leaves the phosphate of iron and alumina. These I filter off, wash slightly, ignite, dissolve in hydrochloric acid, reduce the iron with zinc until neutral, acidulate with sulphuric acid, dilute, and titrate with permanganate. The results obtained in this way agree very closely with each other. It is better for this purpose to have a weaker solution of permanganate, say $\frac{1}{20}$ normal.

Manganese.—The estimation of manganese gravimetrically is not at all an easy or satisfactory operation. The different precipitates have an extraordinary tendency to retain alkaline salts, and also on ignition it is extremely difficult to obtain the protosesquioxide in a fully oxidized state. It must also be separated from nearly every other base or they precipitate along with it.

But volumetrically, fortunately it is extremely easy to estimate it with the greatest accuracy. If solution of permanganate is added to a neutral or nearly neutral hot solution of a manganese salt, there is a precipitation of the manganese contained in both of them as dioxide.

$$2\,H_2O + K_2Mn_2O_8 + 3\,MnSO_4 = 5\,MnO_2 + K_2SO_4 + 2\,H_2SO_4.$$

The sample to be analysed is dissolved in aqua regia, diluted largely, neutralized as nearly as possible with Na_2CO_3, which is added until the precipitate which forms redissolves with difficulty, the solution heated nearly to boiling and permanganate solution added from the burette. A brown-black precipitate falls, which rapidly subsides, leaving a clear supernatant liquid, which remains colourless till the whole of the manganese is precipitated, when it retains a rosy-red colour. With care, it is easy to titrate it to a drop, and the results are very satisfactory. Any bases, other than manganese, which may be in the sample, are in a fully oxidized state, and do not at all interfere with the process. It is a point that the neutralized solution should be nearly boiling, as at lower temperature different reactions occur.

The manganese in an ore may also be determined by dissolving it with dilute sulphuric acid and a weighed quantity of pure oxalic acid in excess, when carbonic dioxide is liberated and 126 parts of crystallized oxalic acid are decomposed by every 87 parts of manganese dioxide present. The solution is diluted, boiled, and the excess of oxalic acid titrated with permanganate in the usual way. This process gives accurate results unless the sample is not completely decomposed by treatment in this way. Some samples of pyrolusite for instance are very difficult of solution. Unless any residue which remains undissolved is of a light colour it is not safe to trust to it. In any case the sample should be powdered exceedingly fine; five minutes with an agate pestle and mortar will often save an hour's subsequent bother.

Calcium is generally estimated gravimetrically by precipitation as oxalate, and conversion of the precipitate into carbonate by ignition. If the heat is very carefully regulated this gives good results, but it is difficult to know when just sufficient heat has been applied to decompose the oxalate, and not so much as to drive off the carbon dioxide from the resulting carbonate. However carefully the heating has been performed, the carbonate is always of a grey colour, and on dissolving it in acid organic matter is left behind. In limestone and similar substances I always use a volumetric process, as I have found it next to impossible to obtain satisfactory results in the other way.

The calcium may be precipitated in the usual way as oxalate, washed, transferred to a flask, acidulated with dilute sulphuric acid, and the oxalic acid titrated with permanganate, which indirectly gives the calcium.

$$5\,CaC_2O_4 + K_2Mn_2O_8 + 8\,H_2SO_4 = K_2SO_4 + 2\,MnSO_4 + 5\,CaSO_4 + 10\,CO_2 + 8\,H_2O.$$

Or a weighed quantity of pure oxalic acid in excess may be added, the solution made up to a bulk and an aliquot portion of the clear filtered liquid titrated with permanganate, which will give the excess of oxalic acid which has been added.

Lime, when in large quantity, as in limestones, I prefer to estimate as follows:—Ignite the precipitated oxalate strongly or at any temperature higher than sufficient to decompose it. Dissolve the resulting carbonate and oxide in standard hydrochloric acid, and neutralize the excess of acid with standard solution of caustic soda. Making experiments with pure Iceland spar I have several times got within ·05 per cent. of the theoretical quantity.

Ferrocyanides.—If permanganate is added to an acid solution of a ferrocyanide it converts it into ferricyanide.

$$10\,K_4FeCy_6 3\,H_2O + K_2Mn_2O_8 + 8\,H_2SO_4 = 10\,K_3FeCy_6 + 6\,K_2SO_4 + 2\,MnSO_4 + 38\,H_2O.$$

About 3 grains of the sample are taken, diluted largely with water, acidulated with sulphuric acid, and standard permanganate solution added until the yellow colour disappears and a faint pink tinge takes its place. The end reaction is not very clearly defined, but a little practice accustoms one to the reaction and a number of analyses of the same sample may be made differing very slightly from each other. Some chemists prefer to add a few drops of dilute ferric chloride solution; this gives a greenish coloration as long as any ferrocyanide is left, and which disappears when the operation is finished. Whether this is advantageous or not seems to depend a great deal on which colour the experimenter is sensitive to.

Ferricyanides may be estimated by first converting them into ferrocyanides. This is effected by boiling with caustic potash, and adding ferrous sulphate solution from time to time until the precipitate which falls is black, and then filtering from the precipitated oxide of iron. The solution is then made very dilute, acidified with sulphuric acid, and the ferrocyanide titrated as before.

Prussian blue may be estimated by boiling with caustic potash, filtering, acidifying, and titrating the ferrocyanide produced with permanganate solution.

$$Fe_7Cy_{18} + 12KHO = 3\,K_4FeCy_6 + 2\,Fe_2 6\,HO.$$

Tannin.—A number of methods have been devised for the estimation of tannin in barks, wood extracts, etc., all claiming superiority, but I am afraid none of them come up to an ideal standard of perfection. The results obtained for the same sample when tested by different methods exhibit a charming variety, and indeed it is a pleasure to get anything like the same result twice together by the same method. The methods generally adopted are all volumetric and I think the best of them is the one devised by Lowenthal, and improved by Neubauer, which consists essentially in oxidizing the tannin by means of permanganate. Whether this process gives the true amount of tannin or not, I cannot say; but, at all events, the same results (or thereabouts) can be obtained from the same sample time after time, so that a comparison can be made of the relative values of different specimens of the same kind of material. This process is described in Sutton's 'Volumetric Analysis,' and in Allen's 'Commercial Organic Analysis.' The fullest description, with the latest improvements, will be found in the latter work. There are one or two curious bits of arithmetic in the calculations, but they will be self-evident to any one who works the process. It is there recommended to separate the tannin with Cologne glue, which I suppose is a kind containing very little oxidizable matter; but it seems difficult to obtain, and I therefore have used isinglass, which answers quite well.

Methyl alcohol.—Permanganate solution has been proposed by Cazeneuve and Cotton (*J. Pharm.*, ii., 361, 367), as a means of estimating the amount of methyl alcohol in ethyl alcohol. There is an abstract of the paper in the *Journal of the Chemical Society*, 1881, p. 198. By using this process, I have succeeded in detecting 10 per cent. methylated spirit (90 ethyl, 10 methyl) in ethyl alcohol, or that is to say 1 per cent. of pure methyl alcohol when mixed with ethyl. In using this process the alcohol should be previously distilled to eliminate colour and organic matter.

Organic Matter in Water.—Permanganate of potassium was years ago in great repute as an indicator of the amount of organic impurity in potable waters, but for a time got into bad odour with chemists, and the results obtained by it regarded with distrust. However, by devising several improvements in the manner of applying it, Dr. Tidy has succeeded in re-establishing its reputation, and it is now once more regarded as a valuable agent in determining the organic pollution of potable water.

I have noticed that whenever we get a bad water to analyse it invariably consumes a large quantity of permanganate solution, and I have come to look on this test as *primâ facie* evidence of organic contamination. A water which rapidly decolorizes permanganate, which when evaporated to dryness gives a coloured residue, and whose residue when exhausted with alcohol and the alcoholic solution on evaporation to dryness leaves a coloured and deliquescent residue, is one which I look on with great suspicion.

A simple way of applying the permanganate test to a potable water is to measure 8 ounces of the water into a *clean* flask, acidulate it with 10 to 20 drops sulphuric acid, and add a solution of permanganate (4 grs. in 10,000) from a burette, until the coloration which is produced by 3 drops does not fade in thirty minutes or so. When the colour remains permanent after that lapse of time, the operation may be considered finished. If, working in this way, the water consumes less than 40 grains of the permangauate solution it may be regarded as sufficiently free from sewage contamination to produce any injurious effects, but if it takes more, further examination is required before it is safe to pass it as a good water. If the permanganate is rapidly decolorized, it points to sewage infiltration; if slowly, to peaty and vegetable matter. If the water is turbid from suspended matter it should be filtered previous to making the test, and the floating matter examined microscopically. This process which is so easy of performance, is of course, not so scientifically perfect as Dr. Tidy's, but as a preliminary test it seems to afford valuable information as to the organic purity, or otherwise, of a potable water.

The uses which I have mentioned are sufficient to show that in permanganate of potassium the chemist has a valuable agent, and one which no doubt can often be beneficially employed.

NOTE ON HYDRARGYRUM FORMAMIDATUM.*

BY JAMES C. WILSON, M.D.

Some accounts of this preparation have appeared in recent journals. Towards the close of last year, Professor Liebreich proposed, in a meeting of the Berlin Medical Society, a new drug for the treatment of syphilis by the hypodermic method. Chemically, this drug belongs to the amide group. Liebreich was led to use it, from the fact that the ordinary amides of the body, of which urea is the principal one, are eliminated in an undecomposed state. When, however, the amide is in combination with a metal, decomposition occurs, and the metal is reduced and deposited. Liebreich found, by actual experiment, that this statement is true of mercury. It is supposed that the formamidated mercury, after hypodermic injection, undergoes decomposition, and that the metal mercury is set free in the tissues. The preparation is soluble in water, of neutral reaction, does not coagulate albumen, is not precipitated by caustic soda, and the presence of mercury can be demonstrated by potassium sulphide. It produces its effects very surely and rapidly. Liebreich regards it as the best remedy known for the hypodermic treatment of syphillis by mercury, as it is but little liable to excite local troubles or salivation. Later (*Med. Times and Gazette*, July 7, 1883), we find that Professor Zeissel, in Vienna, after trial of this remedy in fifteen cases of syphilis, was well satisfied with the results. In three of these cases salivation was produced. Some pain followed its injection, which was not, however, so severe as that following the hypodermic use of mercuric chloride. Twenty injections was the maximum number required to disperse the manifestations, even in severe cases.

Dr. Schacht, of Berlin (*New Remedies*, September, 1883), writes as follows:—

"Formamide is a colourless liquid, boiling at about 195° C., which can be distilled without decomposition only *in vacuo*. It is prepared by acting upon formate of ethyl by ammonia. When pure it is neutral, but easily becomes acid.

"If a *concentrated* solution of formamide be *boiled* with precipitated mercuric oxide, decomposition ensues, and metallic mercury is separated.

"On the other hand, if a dilute solution of formamide be *warmed* on the water-bath with precipitated mercuric oxide, a clear, colourless solution results, in which soda (hydrate of sodium) produces *no* precipitate. Sulphide of ammonium, however, precipitates the mercury as sulphide, both from the formamide of mercury and from mercuric chloride. Solution of albumen is precipitated by the latter salt, but not by the formamide.

"Formamide of mercury is prepared in the following manner:—10 to 13 grams of freshly precipitated, completely washed and still moist mercuric oxide are generally warmed with a little water in a porcelain capsule, with gradual addition of 10 grams of formamide. As soon as solution has taken place, the resulting colourless liquid is filtered into a litre-flask, and the latter filled to the litre-mark with distilled water. Each cubic centimetre contains 0·01 gram of mercury, which is the quantity representing one hypodermic dose. Formamide of mercury keeps well in brown-coloured bottles, and should also be dispensed in these."

In a note from Vienna (*Med. News*, October, 13, 1883), it is stated that Professor Neumann is now trying hydrargyrum formamidatum on a large scale as an antisyphilitic. It is used hypodermically in doses of 1 c.c. It acts with far greater efficacy upon the recent efflorescences than upon the later manifestations. Pain of great severity and active local inflammatory troubles have resulted in Neumann's cases.

The preparation I exhibit, made by Merck, of Darmstadt, is a 1 per cent. aqueous solution, and the dose of it is from half to one ordinary hypodermic syringeful.

It has not been possible to obtain this drug in Philadelphia until the present time.

THE USE OF LITMUS, METHYL ORANGE, PHENACETOLIN AND PHENOLPHTHALEIN AS INDICATORS.*

BY ROBERT T. THOMSON.

The number of indicators which have been proposed to supersede litmus is now very great, but none, as far as I am aware, have been thoroughly tested as regards their efficiency in presence of the impurities which constantly occur in the alkaline hydrates and carbonates of commerce. There is no lack of information to be obtained concerning the high tinctorial power of these indicators compared with that of litmus, and their delicacy when

* Read before the Chemical Section of the Philosophical Society of Glasgow, January 22, 1883, and reprinted from the 'Proceedings.'

employed in the determination of alkalies in solutions of the pure hydrates and carbonates; but on the question of their value in presence of sulphites, thiosulphates, sulphides, phosphates, silicates, aluminates, etc., little or no attention has been bestowed.

In the following paper are detailed the results of a series of experiments I carried out with the view of testing, in as complete a manner as possible, the merits of litmus, methyl orange, phenacetolin, and phenolphthaleïn as indicators in the estimation of alkalies and certain free acids. Instead of taking these indicators in succession, and recording all the tests made with them, I have considered it preferable to take the substances which were tested by the standard acid or alkali, and state the result obtained with each indicator. By this means a close comparison of the behaviour of the different indicators with the same substance will be secured.

The tests were made in such a way that the solution employed would measure about 100 c.c. when the end-reaction was observed. The strengths of the indicator solutions (·5 c.c. of which was used for every experiment) were so arranged that equal volumes of each gave, as nearly as could be judged from their different tints, the same intensity of colour at the point at which the change caused by the addition of excess of acid or alkali was just complete.

I.—Delicacy of the Indicators in Absence of Interfering Agents.

This was tested by adding the ·5 c.c. of the indicator solution to 100 c.c. of distilled water, and finding how much decinormal acid or alkali (1 c.c. = ·0031 gram Na_2O or ·004 gram SO_3) was required to change the colour.

Litmus.—This indicator, as is well known, is naturally blue, and remains so in presence of alkalies and alkaline carbonates, but changes to red when a slight excess of acid is added. The litmus solution employed contained 20 grams of the dry extract per litre. Half a c.c. of this was mixed with 100 c.c. of distilled water, and decinormal sulphuric acid added from a burette, drop by drop, till no further alteration in colour was observed. To accomplish this ·5 c.c. of the acid was consumed. This is equal to ·05 c.c. (about 1 drop) of normal acid, which is the strength usually employed in alkalimetric tests.

Methyl orange.—It is soluble in water with formation of an orange yellow liquid, which is unchanged in colour by alkalies or alkaline carbonates and bicarbonates, but is transformed to a deep pink by a mineral acid. The solution employed contained ·15 gram of the methyl orange per litre, and ·5 c.c. of decinormal acid was required to effect a complete change in the colour, when tested in exactly the same way as the litmus solution. It is thus on an equality with litmus as regards delicacy in absence of all salts.

Phenacetolin.—This substance is soluble in alcohol with formation of a dark brown liquid, which gives with the hydrates of potassium and sodium, even in presence of carbonate, a scarcely perceptible yellow, with ammonia and the normal alkaline carbonates a dark pink, with the bicarbonates a much more intense pink than with the normal carbonates, and with mineral acids a golden yellow colour. The solution employed contained 2 grams of phenacetolin per litre, and was tested by decinormal carbonate of sodium, of which ·1 c.c. was required to produce a decided change from a faint brown tinge to a dark pink.

Phenolphthaleïn.—This indicator gives rise to a fine red colour in presence of alkaline hydrates and carbonates, but with bicarbonates (in absence of normal carbonates) and free acids no colour is produced. Phenolphthaleïn is almost insoluble in water, but is readily soluble in 50 per cent. alcohol. The solution used contained ·50 gram per litre, and was of a pale yellow colour, which was probably due to a slight impurity. When tested under the conditions observed in the case of the other indicators, ·1 c.c. of decinormal hydrate of sodium caused a sudden transformation, the colourless solution becoming red.

In the following Table (I.) will be found a summary of the results given above.

Table I.

Showing the delicacy of the indicators in the absence of interfering agents.
Amount of distilled water used for each test . . 100 c.c.
Amount of indicator solution used for each test . 0·5 c.c.

Name of Indicator.	Grams of Solid Matter per litre of Indicator solution.	Amount of decinormal acid or alkali required to change colour of indicator.
Litmus	20·0	·5 c.c. H_2SO_4
Methyl orange .	·15	·5 c.c. "
Phenacetolin . .	2·0	·1 c.c. Na_2CO_3
Phenolphthaleïn .	·5	·1 c.c. NaHO

II.—Application of the Indicators to the Determination of Soda existing as Hydrate with a small Proportion of Carbonate.

The solution of caustic soda employed was of normal strength, and each test was made with 50 c.c., which thus contained 1·55 gram of available soda. The soda existing as carbonate in this quantity was ·024 gram and was estimated by precipitation with chloride of barium.

Litmus.—When this indicator was used exactly 50 c.c. of normal sulphuric acid were consumed. The solution was, of course, boiled thoroughly after each addition of acid, especially when near the neutral point, and only a single drop was required to effect the end-reaction.

Methyl orange.—The great advantage claimed for methyl orange over litmus is that with the former no boiling is required, as carbonic acid has no effect on the colour. On making several determinations of soda with this indicator, I found that its delicacy was by some means considerably impaired, as the pale yellow colour became just perceptibly tinged with pink when 49·95 c.c. of the normal acid were added. The change in colour was very decided when 50, but was not fully developed till 50·15 c.c. were consumed. In these cases ·2 c.c. of the acid was necessary to bring out the full intensity of colour, while ·05 c.c. produced the same result in absence of interfering agents. It would be naturally expected that if half the quantity of methyl orange were used, a proportionately more delicate end-reaction would be secured, but at least ·15 c.c. of the normal acid was required to occasion the alteration in tint. Again, the same expectation might reasonably be entertained with regard to varying the proportions of soda, but I found that when ·775 gram of soda was tested ·15 c.c., while with 3·1 grams of soda, ·25 c.c. of the test acid was indispensable in effecting the complete transformation. It is evident that this extension of the end-reaction over from ·15 to ·25 c.c. of normal acid must be due, either to the liberated carbonic acid, or to the salt of sodium produced by the action of the acid on the hydrate and carbonate of sodium. That it is solely owing to the latter cause I shall show when the action of the neutral sulphates, chlorides and nitrates of the alkalies is under consideration. On looking over these results the question arises, At what point is the estimation of alkali, when methyl orange is used as indicator, to be reckoned as finished? The point I have adopted is that at which the first *decided* change in colour is apparent, and this end-reaction coincides exactly with that of litmus. The intensification of the colour by the further addition of acid serves as a confirmation of the first reading. Greville Williams, in a paper which appeared in the *Chemical News*, xxxix., 98, recommends for each determination the use of from ·1 to ·2 c.c. of a solution containing ·1 gram of methyl orange per litre. The larger of these quantities is about one-fourth of that which I have employed, and when excess of acid is added gives a very faint pink colour, which is sensibly less intense in presence of much sulphate of sodium. It is obvious, however, that the amount of the indicator solution used must be varied according to the volume and colour (if any) of the solution in which the alkali is to be determined.

Phenacetolin. — This indicator was introduced by Degener for use in the determination of the respective proportions of hydrate and carbonate of sodium in the same solution, and was tested by Professor Lunge, whose results will be found in the *Jour. Soc. Chem. Industry*, i., 55.

To determine the hydrate of sodium the normal acid was added till the scarcely perceptible yellow colour gave place to a rose-pink, which remained permanent for a few minutes at least. Two tests gave respectively 49·1 and 49·2 c.c. of acid consumed, which are equal to 1·523 and 1·526 gram of soda existing as hydrate, as against 1·526 obtained by deducting the soda existing as carbonate (which was determined by chloride of barium) from the total soda. It must be carefully borne in mind that the rose colour should be permanent, for it may be developed by adding a drop of the acid, even when there is still a little hydrate present, and then fade slowly away. The first reading can be confirmed by adding a drop or two more acid, which should render the colour more intense.

To find the proportion of soda existing as carbonate the addition of acid was now continued. The colour at first was intensified, then became mixed with yellow, and finally all the pink tinge was eliminated, and a golden yellow was produced. For each test 50 c.c. of the normal acid were consumed, thus giving in the one case ·9 c.c. for the soda as carbonate, and in the other ·8 c.c., showing respectively ·027 and ·024 gram of soda existing as carbonate, as against ·024 estimated by chloride of barium. A much sharper end-reaction is obtained by boiling off the carbonic acid after each addition of acid when determining the portion of soda existing as carbonate.

Phenacetolin is not adapted to the estimation of small quantities of hydrate in presence of a large proportion of carbonate of sodium or potassium, as is evident from the following test. To a solution containing 2·65 gram of carbonate of sodium and 0·4 gram of hydrate of sodium in 100 c.c., phenacetolin was added, but even after an hour had elapsed the dark pink colour did not disappear, as it should do if the process were of any value.

Phenolpthaleïn.—This indicator, which seems first to have been employed by Luck in that capacity, can also be used for the determination of the proportion of hydrate and carbonate of sodium in the same sample. The method of procedure is to add the normal acid to the cold alkaline solution till the red colour is discharged, taking care, by using a dilute solution and keeping the point of the burette in the liquid, that no carbonic acid escapes. The point at which the colour is dispelled is when all the hydrate is neutralized, and the carbonate has been converted into bicarbonate according to the following equation:—

$$2Na_2CO_3 + H_2SO_4 = 2NaHCO_3 + Na_2SO_4.$$

By this means the whole of the soda existing as hydrate and half the soda as carbonate is determined. The number of c.c. consumed is now noted, and the estimation continued, boiling thoroughly after each addition of acid to decompose the bicarbonate of sodium, and thus bring back the red colour. It is preferable, as pointed out by Warder in his paper in the *Chem. News*, xliii., 228, to add excess of normal acid, boil off the carbonic acid, and titrate back with normal caustic soda. The results of several experiments gave 49·6 c.c. of normal acid consumed for the hydrate and half the carbonate of sodium, and 50 c.c. for the total available soda, or, in other words ·8 c.c. for the carbonate and 49·2 for the hydrate. These results agree almost exactly with those obtained by the estimation of the carbonate of sodium by barium chloride, and with the use of phenacetolin as indicator. It must be noted that the more carbonate of sodium there is present the less delicate will the end-reaction be, as the red colour gradually fades away during the first portion of the titration. It is also evident, from the nature of the process, that this method is quite unreliable for the determination of a small quantity of hydrate of sodium in presence of a large proportion of carbonate of sodium.

Table II.

Showing results obtained by each indicator when used in the determination of soda in caustic soda containing a little carbonate of sodium.

Soda, existing as hydrate, employed . 1·526 gram.
Soda, existing as carbonate, employed. ·024 gram.
Total soda employed . . . . 1·550 gram.

Name of Indicator.	Grams of total Na_2O found.		Grams of Na_2O as hydrate found.		Grams of Na_2O as carbonate found	
Litmus	1·55	1·55	...		...	
Methyl orange .	1·55	1·55	...		...	
Phenacetolin . .	1·55	1·55	1·523	1·526	·027	·024
Phenolphthaleïn .	1·55	1·55	1·526	1·526	·024	·024

III.—Estimation of Available Potash in Caustic Potash.

It is quite unnecessary for me to give any details of the results of the experiments made under this head. Litmus and methyl orange can be used for the determination of the total available potash, and phenacetolin and phenolphthaleïn for the estimation of the respective proportions of hydrate and carbonate of potassium with as great accuracy as in the case of the caustic soda.

IV.—Estimation of Ammonia existing as Hydrate.

The liquor ammonia used for the following tests did not contain an appreciable quantity of carbonate, and was free from other impurities. It was diluted with an indefinite quantity of water, and 50 c.c. of the dilute sample were employed for each determination. This quantity, according to a result obtained by converting the ammonia into chloride of ammonium and drying at 100° C., contained ·547 grams of ammonia (NH_3).

When litmus, methyl orange, or phenacetolin was used, exactly 32·4 c.c. of normal sulphuric acid were consumed, which are equal to ·550 gram of ammonia. The end-reactions in each case were quite as delicate as with caustic soda. As phenacetolin produces with ammonia the dark pink colour characteristic of its reaction with the carbonates of sodium and potassium, and not the faint yellow formed with the hydrates of these metals, the respective proportions of hydrate and carbonate of ammonium cannot be determined by titration in presence of this indicator.

In the two determinations made with phenolphthaleïn as indicator 31·5 c.c. and 31·4 c.c. of the normal acid were consumed. After 25 c.c. had been added the colour began to fade away slowly, and was fully discharged at the point mentioned. These results show respectively ·535 and ·533 gram of ammonia, and are so far below the truth as to be equal to about 3 per cent of the whole ammonia present. It is, therefore, perfectly plain that phenolphthaleïn is utterly useless for indicating the end-reaction in the estimation of ammonia. The anomalous behaviour of phenolphthaleïn is due to the action of the salt of ammonium which is formed, and which destroys the red colour produced by the ammonia when the proportion of the latter becomes small. That this is the true explanation will be shown when the effect of the neutral salts of ammonium on the indicators comes to be examined.

(To be continued.)

THE BENEVOLENT FUND.

In the present number of the *Pharmaceutical Journal* unusual prominence is given to the subject of an institution which indisputably has a claim upon the attention of every registered chemist and druggist in the United Kingdom. It is to the honour of our country that there exist in it many organizations for the relief of the indigent and sick, some of which are general in the scope of their operations, whilst others are confined within more or less restricted limits. But there is no arrogance in the assertion that not one of them is more worthy of support from the class to whom it specially appeals than the Benevolent Fund which was founded more than forty years ago by the earliest leaders of the Pharmaceutical Society, and which is still administered by the Council of that body. Instituted originally with the object of providing for the relief of any who were in distress among the Members and Associates of the Society or their widows and orphans, the true nucleus of the Fund was constituted by a donation in the year 1842 of £500 from the general assets of the young Society, and this was increased by similar sums set aside from the Society's funds in 1843 and in 1844. These sums, together with all the donations, were invested, and to this funded capital were added at intervals any unexpended balances of subscriptions and interest left from the gradually increasing annual income, until in the Annual Report for 1865, when the investments amounted to nearly £6500, the Council felt warranted in recommending the Society to incur the responsibility of granting annuities. In that year accordingly two persons were chosen to receive the sum of £30 each annually from the Fund, and since then no year has passed without the election of fresh annuitants. Up to that time previous connection with the Pharmaceutical Society had been a qualification essential to a successful application for assistance; but a desire to extend the sphere of the application of the Fund induced the Council, which was just then seeking the legislation that came eventually in the shape of the Pharmacy Act, 1868, to avail itself of the opportunity to obtain powers that would authorize the extension of the benefits of the Fund to the needy of the whole body of qualified chemists and druggists as constituted by that Act. In order to appreciate properly the liberality of this course, it must be remembered that the Pharmaceutical Society was not then nearly so representative of the trade as it is now, and the immediate effect was to extend the potential scope of the Fund from about 2500 persons to more than 12,500. Nevertheless, two years afterwards, in 1870, another donation of £500 was voted from the funds of the Society to be invested in what had now become a General Benevolent Fund for chemists and druggists. In addition to this it may be stated that from its initiation the Fund has been administered by the Council of the Pharmaceutical Society and has never been subjected to any of those expenses for management which constitute so serious—and yet unavoidable—a charge upon the income of nearly all benevolent institutions.

It is not surprising therefore that, fostered thus carefully, the Fund has prospered. The investments now amount to £19,400, whilst the income from annual subscriptions and donations last year reached the respectable sum of £1922. On the other hand, the annuitants have now increased to forty—a number which bears no unworthy proportionate relation to the total number of registered chemists and druggists, and which represents an annual sum of £1350, whilst the money expended last year in casual relief amounted to £675. The Fund has therefore now attained proportions, both in respect to its receipts and its expenditure, upon which all chemists and druggists may well be congratulated, especially since it can now be officially declared that "no genuine case of necessity presented to the Council is left unaided by temporary assistance." In order, however, to maintain this degree of efficiency, not only has the Council to exercise the greatest vigilance through its Committee in the careful examination of all applications for help, but it has also continually and persistently to urge the claims of the Fund to the generous consideration of all chemists and druggists who are in a position to contribute towards the alleviation of the distress of their less prosperous brethren.

There is one direction, however, in which the repeated appeals of the Council have not been responded to in the degree that might have been expected. We refer to the large number of chemists and druggists that still abstain from connecting themselves with the Pharmaceutical Society as Members or Associates, and who, apparently as a corollary, do not subscribe to the Benevolent Fund that it dispenses. For it is a fact, that whilst nearly 50 per cent. of the Members and Associates of the Society subscribe to the Fund, only about 11 per cent. of the registered chemists and druggists outside the Society contribute to it. Or, to put the case in another form, the nine thousand chemists and druggists unconnected with the Society between them only subscribed last year £385 12*s.* 8*d.*, while the class of Pharmaceutical Chemist Members of the

Society alone subscribed £516 19*s.* 6*d.* Nevertheless there is no ground for supposing that chemists and druggists outside the Society are less willing to relieve the distress of the afflicted to the best of their ability than those who are connected with it. It is thought probable rather that, notwithstanding the numerous occasions on which the Fund has been brought under their notice, they still remain imperfectly acquainted with the catholic character of the Fund and the advantageous conditions under which it is administered. It is in the hope of promoting the removal of any such remaining misapprehension or prejudice on the subject that the occasion of sending a copy of this Journal, containing a classified list of Subscribers and Donors to the Fund, to every chemist and druggist on the Register, is utilized once more to explain the character and urge the claims of this valuable institution. In the first place it may be stated that the relief afforded from the Fund is given in two forms. Urgent cases are helped temporarily by grants of money based upon the recommendation of a Committee charged with the investigation of the *bona fides* of each application. Other cases, which are thought worthy of more permanent help, are also placed on the list of approved candidates, from which a certain number, dependent upon financial considerations, are elected every year by the subscribers and donors themselves to receive annuities for the remainder of their lives. During the year 1883 the money expended in temporary aid amounted to £660 10*s.*, of which sum £260 went to registered persons, £330 to widows, and £70 10*s.* to orphans. The annuities paid during the same year to forty-two men and women above sixty years of age amounted to £1283 15*s.* With respect to the recipients, it cannot be too distinctly stated that no other qualification for relief from the Fund is ever required than that the application is made on behalf of a person whose name is on the Register of Chemists and Druggists, or the widow or children of such a person, and that it can bear the test of an inquiry. Indeed, it may be mentioned here that the grants and annuities received last year by persons who had never been connected in any way with the Pharmaceutical Society exceeded by far the amount subscribed by persons outside it. The Fund is maintained by annual subscriptions and donations, which may be paid to any Local Secretary of the Society, or forwarded direct to the Secretary, Mr. ELIAS BREMRIDGE, 17, Bloomsbury Square, W.C. Every person subscribing half-a-crown annually is entitled to one vote at each election of annuitants, whilst each half-a-guinea represents five votes. By giving five guineas in one sum a person may become a life subscriber with five votes at each election, and each additional guinea will entitle him to another vote. Similar donations from firms or corporations entitle them to the same number of votes during ten years. In conclusion we express the hope that this simple statement may prepare the way in many instances for a favourable reception of the local secretary or whoever else may be seeking contributions to the Fund.

SCHOOL OF PHARMACY.

As will be seen by the advertisement in the present number, the courses of lectures on "Chemistry and Pharmacy" and "Materia Medica and Botany," in connection with the Pharmaceutical Society's School of Pharmacy, 17, Bloomsbury Square, will recommence on Saturday, March 1, at 9 a.m., when Professor BENTLEY will give his first lecture on Botany. Professor REDWOOD will commence his course on "Chemistry and Pharmacy" on Monday morning, March 3, at 9 o'clock.

Students will find the ensuing five months a favourable period for studying at the School, for between March 1 and the end of July they will have an opportunity of attending not only Practical Chemistry in the laboratories and the usual courses of lectures on Chemistry and Pharmacy and Materia Medica and Botany, but also the summer course on Practical Botany and the Classification of Plants, at the Royal Botanic Society's Gardens, in the Regent's Park, where every opportunity will be afforded to them of obtaining a practical acquaintance with medicinal plants and the natural orders.

In addition to the above courses of lectures and Practical Chemistry, there is also Mr. INCE's class for "Practical Instruction in Dispensing," which will recommence on Tuesday, March 4, and be continued until the end of July.

THE CHEMISTS' ASSISTANTS' ASSOCIATION.

IT is pleasant to be able to congratulate the Chemists' Assistants' Association once more on the success of its Annual Dinner, which was held on Wednesday evening last, at the Holborn Restaurant, under the presidency of Mr. S. R. ATKINS, the Vice-President of the Pharmaceutical Society, one hundred and fifty members and their friends being present. The Chairman, in proposing the "Medical Profession," referred to the great amount of unpaid labour and the other important services which the members of it are continually rendering to the public. On the one hand, he said, the eminent London specialist is consulted by the friends of the peer, and on his decision, as the ultimate court of appeal, life or death may be said to hinge; and on the other, the hard-worked, ill-paid provincial practitioner is summoned long distances, regardless of wind and weather, to attend the wife or child of the peasant. He took the opportunity, also, to remark that pharmacists wished to be true to the traditions of the Pharmaceutical Society and to keep to their own line of action, whilst they hoped that the medical profession would keep to theirs. Dr. H. MACNAUGHTON JONES, in replying, reviewed the progress of knowledge of disease during the past forty or fifty years and said that much of this had depended on the valuable assistance of pharmacists. Speaking as an examiner he regretted that medical students were not compelled to learn more pharmacy than was now required of them. In his opinion the prescribing of proprietary preparations by medical practitioners went dangerously near to empiricism. The toast of the "Pharmaceutical Society" was proposed by Mr. Millhouse, who said that the claims of the Society for further State recognition were based upon the technical education which had been provided and fostered by it. Mr. Greenish replied, and referred to the absence of community between members of the trade before the institution of the Society, and he drew a contrast between the educational facilities of to-day and those which existed forty years ago. The Chairman then proposed the toast of the evening, "The Chemists' Assistants' Association," and referred to the great advantages which the Association afforded from a social point of view, and also to its claims to recognition on account of the good scientific and practical work which it was doing. Mr. Parkinson, in replying, spoke of the formation and subsequent work of the Association, and said he hoped it would soon become self-supporting and would not have to depend upon the subscriptions of gentlemen who were not members of it. He thought there ought to be a sufficient number of members to make the Association a success financially. The toast of "The Visitors" was proposed by Mr. Winfrey and replied to by Professor Attfield, and, lastly, that of "The Chairman" was proposed by Mr. Braithwaite and suitably acknowledged by Mr. Atkins.

In the evidence given by Dr. Campbell Brown at the recent trial of two women at the Liverpool Assizes for the murder by poisoning of the husband of one of them, he stated that the liquor contained in a flask produced was a neutral solution of arsenic, resembling the liquor which he had obtained by extracting eight out of nine samples of fly paper with water. Although Dr. Brown does not seem to have committed himself absolutely to the theory that fly papers had been the source of the arsenic used in the poisoning, it is understood that one of the prisoners, since her conviction, has admitted that this was the case. We venture, therefore, to remind our readers that about five years since (*Pharm. Journ.*, [3], viii., 1039), Mr. Plowman called attention in our correspondence columns to the prevalence of arsenical fly papers, and the evil results that might be consequent on their unrestricted sale.

* * *

The proceedings under the Massachusetts Adulteration Act for the sale of faulty drugs, to which reference was made a few weeks since, appears to have created much uneasiness among the druggists of the State. As one consequence a letter has been addressed by the President of the Boston Druggists' Association, Professor Markoe, to the Board of Health, asking that any druggist who may be found to have supplied an article in violation of the law may receive official notification of the fact and that prosecutions may not be instituted except when a person continues to sell the challenged article after receiving such a notice. The Board has, however, declined to take the course suggested, on the ground that it would be neither reasonable nor just and would make the "Board directly responsible for the condition of the whole drug market." The *Sanitary Engineer* goes further and describes the request as "a piece of effrontery that we have seldom seen equalled

* * *

We understand that Herr Knapp, the Curator of the Herbarium of the Vienna General Pharmaceutical Association, is to accompany a scientific expedition that will start next month for Northern Persia to explore the fauna and flora. It is to be hoped that the journey may incidentally contribute to our knowledge of materia medica.

* * *

Notwithstanding the existence in New Zealand of a "Sale of Poisons Act" which, although it allows scheduled poisons to be sold by others than qualified pharmacists, contains provisions as to the registry of sales, labelling, etc., similar to those in the British Pharmacy Act, the Colonial Government has recently by an Order in Council added other restrictions upon the sale of arsenic and strychnia. Henceforth it will be illegal for any person in New Zealand to sell either of these poisons unless before making the requisite entry of the sale he obtains from the intending purchaser a statutory declaration setting forth his or her name, occupation and address, the exact quantity of the poison required, the express purpose for which it is intended to be used, and the place or places where it is to be used or deposited. Immediately after the completion of the sale the seller is to forward the statutory declaration to the registrar of the district. A meeting of pharmacists was to be held in Dunedin to consider the effect of this Order.

* * *

Professor Bentley, Professor Attfield and Mr. E. M. Holmes have been elected Honorary Members of the Philadelphia College of Pharmacy, "as a mark of respect for their scientific researches and acquirements." Professor Attfield was elected a Corresponding Member in 1869.

* * *

On Friday, the 15th inst., the Institute of Chemistry Bill was presented in the House of Lords, read a first time, and referred to the Examiners.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, the 27th inst., when a paper on "Coal Tar Derivatives used in Pharmacy" will be read by Mr. Joseph F. Burnett.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, February 28, at 8 p.m., when a paper on "Some Silicon Compounds" will be read by Mr. F. MacDiarmid, and a Report on Botany will be made by Mr. E. Baily.

* * *

The next meeting of the Manchester Pharmaceutical Association will be held at The Owens College (Coupland Street entrance), on Tuesday evening next February 26, at 7.30 p.m. when the following papers will be read:—"Disinfectants," by Mr. W. Kirkby, and "A Note on Exotic Henbane," by Mr. W. Elborne.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The annual general meeting was held in the Society's Room, on Wednesday evening, February 6. Mr. J. Preston, the retiring President, in the chair.

The minutes of the last general meeting were confirmed.

The Secretary announced that the following donations had been received during the year:—The *Pharmaceutical Journal*; Calendar of the Pharmaceutical Society; Register of Chemists and Druggists, from the Pharmaceutical Society of Great Britain; the 'Year-Book of Pharmacy,' from the British Pharmaceutical Conference.

It was unanimously resolved, on the motion of the President, that the best thanks of the Society be given to the respective donors.

On the motion of Mr. Smith, seconded by Mr. Marshall, Messrs. Brookes, Chatterton, Cobban, Grierson, Holleley, Humphrey, Jacques, Johnson and Kite were elected Associates of the Society.

The Annual Report was then read by the Secretary, as follows:—

"Annual Report, 1883.

"Your Council in again presenting its report for the year would call attention to the following items of business:—There have been five general meetings and six Council meetings, all of which show a full attendance and testify to the vitality of the association.

"The financial condition of the Society is a matter of congratulation, inasmuch as the balance in hand has not been greatly touched upon, especially when we consider the extraordinary calls which have been made upon it. The receipts for the current year amount to £10 5*s.* 1*d.*, which is mainly made up of the small subscriptions. This with balance in hand, £16 16*s.* 2*d.*, brings the total to £27 1*s.* 3*d.* The expenditure for the year is made up as follows:—Rent, £5; gas, 10*s.*; coals, 2*s.* 3*d.*; insurance, 3*s.*; printing, stationery and other secretarial expenses, £8 2*s.* 3*d.*, make a total on the other side of £13 17*s.* 3*d.*, which, with bank interest 7*s.*, leaves a clear balance in hand of £13 11*s.* 0*d.*

"It will be noticed that the balance now in hand is a decrease on that of last year, but this is owing to the extraordinary demand which has been made upon the funds, and which is not likely to occur again. The Council would suggest that the original sum of 10*s.* for membership should be again adopted.

"A pleasing feature of the year's work is that gentlemen not directly connected with the trade have freely given their edifying services, whose efforts were fairly appreciated by the full attendances at the respective meetings. Your thanks are specially due to Messrs. Hibbert and Wood. The services of members of the association have greatly contributed to maintain the life and activity which has marked its career during the year.

"A special meeting of the members of the Society and the trade was called during the year to consider the proposed Pharmacy Acts Amendment Bill, the discussion on which was fully reported in the pages of the *Pharmaceutical Journal*, and at no little expense to the Society, but your Council has the satisfaction of knowing that the views then enunciated were respectfully considered, and appreciated in high quarters and elsewhere.

"During the year a communication with respect to the Pharmacopœia revision was discussed at one of the Council meetings, and the action then taken we have reason to believe was much appreciated by the Pharmaceutical Society of Great Britain.

"At the meeting of the British Pharmaceutical Conference at Southport, in September last, your Society was represented by Messrs. Furness, Learoyd, Newsholme and Ward as delegates.

"Your Council has perseveringly kept the subject of education before it, and a scheme was propounded and inaugurated, the lecturers of Firth College considerately adapting their course of lectures and laboratory practice to the requirements of the curriculum of the Pharmaceutical Society. These efforts have met with some success, and your Council believes that the small beginnings augur hopefully for Sheffield as a pharmaceutical centre. The efforts in this direction will not be relaxed until circumstances prove that they are no longer needed.

"Your Council has been greatly encouraged by the increased attendance at the monthly meetings, especially of the younger members of the trade, and it recognizes with gratitude the growing desire amongst many to fit themselves for the high position which they will probably, at no distant time, have to occupy.

"Your Council also desires to record the fact that a junior association has lately sprung up, holding its meetings in the Society's rooms twice a week, having for itself a President in the person of Mr. N. S. Smith, 4, High Street, and a Secretary, Mr. J. Marshall, 74, Market Place, the objects of the Association being purely intellectual, viz., for the study of the subjects required for the Minor examination and on the principle of mutual improvement; judging from its beginnings it will doubtless prove helpful to all concerned.

"In conclusion, your Council feels that it cannot close this report without again referring to the good work the Society is doing, not only in promoting good feeling amongst the chemists generally, but in providing opportunity for mutual benefit and improvement."

The adoption of the report was moved by Mr. Preston, and seconded by Mr. Maxey, and carried unanimously.

The election of President now took place.

Mr. W. Ward, in proposing that Mr. Preston be again elected to the Presidential chair, referred to the good work done by him during his two years of office, and said that the Society had never been in so prosperous a condition as at the present time, and that Mr. Preston had contributed largely to this by his energy and attention to the interests of the Society.

Mr. Furness seconded the resolution, which, being put to the meeting by Mr. Ward, was carried unanimously.

Mr. Preston, on rising, said that whilst he accepted the office of President for the third time he did so reluctantly. He considered that they had greatly honoured him in proposing him again, and he should not have been induced to accept the responsible position had it not been for the pressing representations made to him. However, in accepting, he did so partly because he had been encouraged by the success which had marked the efforts of the Council in the past; a success which was evidenced by the increased attendance at the monthly meetings and the lively discussions which had ensued, also by the increased numbers which had recently joined their ranks, especially from amongst the younger members of the trade. He believed that it was better that new blood should be alike introduced into the Presidential office as well as into the body corporate of the association, and this conviction was dead against the position he now took up. He would have refused to undertake the duties they now desired him to take, if by doing so he would not have laid himself open to a charge of sheer stupidity, and inasmuch as he did not lay claim to belong to the particular animal which bore this character he bowed to the wish of his *confrères*. In looking forward to the future, his hopes were that, the Society would prove still more useful to its members, by that mutual interchange of opinions, on trade topics, so necessary, in the present condition of trade, with its varying usages and in the hard competition going on all around. He believed that it could be made still more useful in a higher sense also, by the reading of papers and discussions thereon of subjects having a pharmaceutical interest; and, it might be, by advancing the chemical knowledge, which the public—an increasingly discerning public—demanded from them. And lastly, not least, certainly, by proving an aid to their younger friends who were now showing a vitality in self-education which was hopeful for the future status of the pharmaceutical chemist. He believed that knowledge in this direction was not only power, but a lever which would, if rightly used, advance their positions in innumerable ways. The absence of this in the chemist of the future would be folly, and must consign the owner of it to a position of ridicule among his fellow men. He recently heard of a case where such a young man, in the last part of his apprenticeship, was asked by a customer what the difference was between "proto sulphate of iron and sulphate," and to his shame he replied, Well, he knew there was a difference, but he was not able to say what it was. To these ends he trusted the Council and members of the Society would press, and with self-denying help from the masters and a wise use of the opportunities which such an association as this, with the help which our local schools afforded, the younger members themselves, he hoped, would be able to acknowledge the benefits which accrued from their membership, remembering that the battle was not always to the strong or to the swift, but to the persevering and the plodding.

The following were the other officers elected for the year:—Vice-Presidents, Mr. J. M. Furness and Mr. Joseph Watts; Hon. Secretary, Mr. G. T. W. Newsholme; Treasurer, Mr. W. Jervis; Auditor, Mr. G. A. Cubley; Council, Messrs. Dobson, Ellinor, Fox, Learoyd, Maxey, Smith and Ward.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eighth general meeting of the thirty-fifth session was held at the Royal Institution, January 31. Mr. Edward Davies, President, in the chair.

The minutes of the previous meeting were read and confirmed and the following donations to the Library and Museum were announced:—'The Annual Report of the Liverpool Amateur Photographic Association, 1883,' from the Association; 'The Year-Book of Pharmacy, and Transactions of the British Pharmaceutical Conference, 1883,' from the Conference; 'The Calendar of the Pharmaceutical Society of Great Britain' and the *Pharmaceutical Journal*, from the Society; and *The Science Monthly Illustrated*, from the Editor.

Mr. L. S. Ward was elected a member.

Mr. A. C. Abraham exhibited a specimen of kola nuts and also a portion of his apparatus for milk analysis.

Mr. A. H. Mason drew attention to a letter from Mr. Blunt, in the *Pharmaceutical Journal*, January 26, in reference to Mr. A. C. Abraham's statement, in the previous week's Journal, that he (Mr. Abraham) believed that the difference in strength in lime water, when made from unwashed lime, was due to the presence of sulphates and chlorides of potash and soda in the chalk, which would be converted into the hydrates during the process of burning. Mr. Mason remarked, that same years ago, *viz.*, in 1874, he had drawn attention to a similar fact, which was recorded in the transactions of that date.

Mr. A. C. Abraham said that as this matter had been referred to, he might point out that while Mr. Blunt had confirmed his statement with regard to the presence of hydrates of potash and soda, he had also strangely stated that the amount which he found was not sufficient to account for the excessive strength noted in the lime water, whereas as a matter of fact, the quantity found by Mr. Blunt would account for this difference many times over.

Mr. Davies thought that Mr. Blunt had probably overlooked the fact that all the hydrates of potash and soda would be taken into solution in the first washing, whereas but a small portion of the lime was dissolved.

The President then called on Mr. J. C. Bredin to read his paper on "Alchemy." The paper gave a very interesting *résumé* of the alchemists of the Middle Ages, and showed how their groping after the secrets of the production of the different forms of matter led to the foundation of the modern science of chemistry. The paper was interspersed with anecdotes, and evinced throughout much care in its compilation.

Mr. Conroy proposed, and Mr. A. C. Abraham seconded, a vote of thanks to Mr. Bredin for the pleasure the meeting had derived from his maiden effort before the Association. The vote was carried unanimously.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Wednesday evening, February 6, the half-yearly meeting of the above Association was held at the rooms, No. 4, Halford Street, when the members sat down to a substantial tea. After which votes of thanks were passed to the retiring Committee, and to Mr. Edwards.

The Honorary Secretary then read the report of the session, in which the fact of one of the present members having passed the Major examination of the Pharmaceutical Society was prominently noticed. It also contained expressions of thanks to the honorary members for their continued support and to the Society and Conference for their supply of Journals and gift of the 'Year-Book of Pharmacy.'

The financial statement shows a balance of about 21*s.* due to the Treasurer; a state of affairs which is considered more satisfactory than in the corresponding half-year of 1883.

A new Committee was elected, from whom Mr. J. J. Edwards was chosen President, Mr. E. Brice Vice-President, Mr. J. Garrett Honorary Secretary, and Mr. W. B. Clark Treasurer.

On the following Wednesday, February 13, the President, Mr. J. J. Edwards, inaugurated the new session with an able description of the microscope together with its uses. Towards the close he exhibited several specimens of starches and physiological substances, to the great delight of his audience.

A vote of thanks to the lecturer, proposed by the Chairman, Mr. E. Brice, concluded the meeting.

EDINBURGH CHEMISTS' ASSISTANTS' AND APPRENTICES' ASSOCIATION.

The eighth meeting of the sixth session of this Association was held in the Pharmacentical Society's rooms, 118A, George Street, Edinburgh, on Thursday evening, February 14, at 9.15; Mr. Claude F. Henry, President, in the chair.

The minutes of the previous meeting having been read and confirmed, the Chairman called upon Mr. William Pirie to read a paper on "Mineral Waters.'

After sketching briefly the origin of springs with the probable manner in which the more common ingredients of mineral water were taken into solution, Mr. Pirie gave some quaint information regarding the composition of mineral waters as related by writers of last century. He then proceeded to discuss the more important waters under four groupings, namely, sulphurous, chalybeate, acidulous and saline. The composition of several of the more common waters was then treated of and the essay was concluded with some thoughtful remarks on the different therapeutical properties of natural as contrasted with artificial saline solutions.

The Chairman, in proposing a vote of thanks to Mr. Pirie, said that he was confident that all had received instruction from the thorough, yet lucid and happy manner in which the essayist had brought the subject before them.

Mr. Turnbull seconded the motion, which was heartily awarded.

There followed a discussion which was taken part in by Messrs. Coull, Crowden, Hill, MacEwan, Stephenson and others.

Queries were then submitted and replied to by many members. The Chairman intimated that at the next meeting Mr. Peter Boa will read a paper entitled "The Cultivation of Taste in the Practice of Pharmacy."

Proceedings of Scientific Societies.

ROYAL INSTITUTION.

The Chemical Work of Wöhler.

On Friday the 15th inst., Professor Thorpe delivered a lecture at the Royal Institution upon "The Chemical Work of Wöhler." Remarking upon the training that Wöhler had received, Professor Thorpe said he entered the University of Marburg in 1820, and though it was the wish of his family that he should study medicine, he never attended any regular course of lectures upon chemistry. The following year, however, he published his first paper on selenium, and soon afterwards placed himself under Gmelin at Heidelberg, with whom he remained until the earlier part of 1825, employing the greater part of his time in the study of prussic acid and other cyanogen compounds. Wöhler then went to Stockholm to study under Berzelius, with whom he stayed a few months, learning his modes of manipulation in mineral analysis, and of whose laboratory he gives a graphic description. Whilst in Stockholm he worked especially upon monoxychloride of tungsten, and succeeded in convincing Berzelius that chlorine was a better name than oxidized muriatic acid. He formed a great friendship with Berzelius, and afterwards translated his 'Jahresbericht.' Returning to Germany the same year, he was appointed to the Technical School at Berlin. In 1827 Wöhler succeeded in isolating aluminium, and in the following year he accomplished the synthesis of urea, which revolutionized previous ideas as to organic compounds. In 1829, he investigated the nature of mellitic acid, and his results were published simultaneously with those of Liebig, who had unknowingly worked upon the same subject and arrived at the same conclusions as Wöhler. Soon afterwards Wöhler returned to the study of cyanic acid, whilst about the same time Liebig and Gay-Lussac experimented upon fulminic acid. The results of these investigations showed that these two acids, though widely differing in their properties, had the same composition; this difference was afterwards explained by Wöhler in his treatise on Isomerism. Becoming acquainted with Liebig, he suggested that they should make a joint investigation upon the benzoyl compounds, which work was very completely carried out in 1832. After a lapse of five years Wöhler made another series of experiments, conjointly with Liebig, upon amygdylin and bitter almond oil; and in the following year, 1838, he made his last important investigation with Liebig, upon the nature of uric acid. Wöhler then gradually turned his attention more towards the analysis of mineral bodies, though occasionally he worked with Liebig, as in the investigation of opianic acid, and on the derivatives of cyanic acid and urea, as well as thialdin and selenaldin. In 1850 he experimented upon the cyano-nitrides of titanium, and in 1852 and the three following years he devoted his time to the study of the tellurium compounds with organic radicals. In 1857, he made, with Ste.-Claire Deville, a joint investigation of boron and the nitrides of silicon and titanium, and in the same year discovered hydride of silicon. In 1860, Wöhler accomplished the last of his principal investigations, that of theobromine, the organic base in cocoa. Though little known in England, Wöhler, who was the first chemist that succeeded in effecting the synthesis of organic bodies, had many distinctions conferred upon him by various societies, amongst which was that of the Copley Medal in 1872. Ten years after receiving this medal he died, at Gottenburg, at the age of eighty-two years.

Parliamentary and Law Proceedings.

Supposed Poisoning by a Narcotic.

Mr. Wightman held an inquest on Tuesday last at Park, Sheffield, on the body of Frederick Castle, aged six weeks.

Sarah Ann Castle identified the body as that of her son. He had been a healthy child, with the exception of crying a great deal. A week ago, as the druggist's shop was closed, she went to a grocer named Mr. Wilcock, in South Street, and asked him if he had anything that would "do for the baby," as it was always crying. He said he had some "stuff," and another person had used a great deal of it. Witness then went and procured a bottle and bought a pennyworth. She did not know what it contained, or what it was called, for there was no label on the bottle, but Mr. Wilcock told her to give the child ten drops. She gave the child the "stuff" at 10.30 on Friday night. About 11.30 p.m. she gave deceased some bread, water and sugar, and then went to bed at twelve o'clock, the child appearing to be as usual. When she awoke at 6.30 the next morning, the child was lying with his hands clasped together and his eyes open, and making a noise. She got up at nine o'clock and left the child in bed, and that was the last time she saw it alive. On going upstairs at 11.35 death had taken place.

The coroner's officer produced a bottle containing a few drops of liquid of a brownish colour. Witness said the bottle was that she had fetched the "stuff" in. There was no label upon the bottle.

The Coroner, after smelling at the contents, said that he thought it contained laudanum and paregoric. He should order a *post-mortem* examination to be made. The inquest was then adjourned.

At the adjourned inquest on Wednesday, Mr. Arthur Hallam, surgeon, said he had made a *post-mortem* examination. The deceased appeared to be about six weeks old, and seemed to be fairly well nourished. He found congestion of the lungs and brain. The appearances were consistent with opium poisoning. That was the cause of death, in his opinion. Death had been slow. If the child had had convulsions it would have died rapidly Mr. Hallam went on to say that the child looked as though it had not had any food for ten or twelve hours before its death. He had seen the bottle which containe the mixture purchased by the deceased's mother, and there was a strong smell of laudanum in it. He could not tell what the mixture was, but he perceived a distinct odour of laudanum. The mixture had not been prepared by a qualified medical man.

The Coroner: What would be the effect of ten drops on a child six weeks old?

Mr. Hallam: Well, I know that a fifth of a grain of opium would kill a child three months old, and that is only equal to two drops of laudanum.

The Coroner here read the evidence of the deceased's mother given the previous day and said: Are these symptoms at all consistent with poisoning by opium?

Mr. Hallam: Certainly.

Mr. Thomas Wilcock said he was a grocer at No. 81, South Street, Park. He had known Mrs. Castle and her husband for three years. He remembered her coming to his shop a week ago last Saturday. She brought a child between two and three years of age with her. She said she wanted some infant's mixture for the child which she had with her, and she purchased a quarter of an ounce of the mixture.

The Coroner: Did you tell her how much to give the child?—Yes; I read it from the label on my bottle.

You did not put a label on her bottle?—No.

How much did you tell her to give the child?—I told her about ten drops would be a proper dose.

Witness, continuing, said he got the mixture from Messrs. Davy Brothers, wholesale grocers, and they got it made up by Mr. Lindley, chemist, Sheffield Moor. He did not know that it contained laudanum, and did not ask what it contained. He sold it by what the label on the bottle said.

The Coroner: Does the label on your bottle say poison?

Witness: No, sir. He advised Mrs. Castle to have some of the mixture because he thought it would do the child good.

The Coroner: How could you recommend that mixture when you did not know what it contained?

Witness: I sold it to another woman, and she used a lot of it.

The Coroner: Would you have objected to give the woman any if she told you it was for the baby?

Witness: I do not think I should have objected, but I should have recommended a smaller dose.

The Coroner: I may as well tell you that if you sell that stuff it is your duty to know what it is; and if it contains poison you are bound to put on a label, which label must contain the name of the article, the word "poison," and the name and address of the seller. It does not matter whether you sell it yourself, or whether your apprentice or assistant sells it. If you do not put a label on it, and it is found that there ought to have been one, you are liable to a penalty of £5 for the first conviction and £10 for the second. Ignorance is no excuse. Whatever may be the result of this inquiry, I think you may go from this room with the conviction that you will be prosecuted, and it ought to be a warning to all in a similar position.

Mr. Wilcock's bottle, from which the mixture was taken, was here produced. It bore the following label:—

"Carminative Mixture for Infants.

Children one to three months old					5 to 10 drops
,,	4 ,, 6	,,	,,		10 ,, 20 ,,
,,	8 ,, 12	,,	,,		half a teaspoonful.
,,	13 months to 3 years	,,			one teaspoonful.

H. Lindley, Dispensing Chemist,
57, South Street, Sheffield Moor."

The Coroner: If this bottle contains opium Mr. Lindley is in the same comfortable position as you are. He is liable as well. (To Mrs. Castle): Will you swear that the bottle which you took had no laudanum in it?—Yes, I will. It had only a little brandy in it.

The Coroner: It is just possible that the mixture does not contain laudanum. According to the smell there does not appear to be much doubt that there is some proportion of laudanum in it.

Mr. Hallam recalled, in answer to the Coroner, said that he was of opinion that the few drops of the mixture left in the small bottle were of a similar nature to that in the large bottle.

The Coroner: Can you undertake to swear that the child died from any narcotic at all?

Mr. Hallam: No, I cannot swear; but I can find nothing else to account for death.

The Coroner said he did not feel justified in closing the inquiry without knowing whether there were narcotics in the mixture or not. The contents of the bottle might be harmless, but it was just as much the duty of the jury to find out that as whether they were hurtful.

The inquest was accordingly adjourned until the 3rd of March, to allow of the contents of the bottle being analysed.

Reviews.

Lectures on Practical Pharmacy. By Barnard S. Proctor. Second edition.*

The name of this well-known writer is quite sufficient recommendation for anything he may have to say on practical pharmacy. He has himself worked out the subjects on which he treats, and the reader has before him in these pages the printed results deduced from long experience.

The present volume constitutes a second and enlarged edition, with much careful revision of the original lectures. The text has undergone general correction, and sundry details have been omitted to make way for necessary additions without a too great increase of space.

The value of the book has been enhanced for reference purposes by a copious index, the absence of which was a defect in the manual as first published. We have still the lecture form retained, and the instruction conveyed is more a record of personal observation than an exposition of teaching derived from accredited sources.

Mr. Proctor is especially good when attempting to describe a pharmacopœial process, an illustration of which may be found in the pages devoted to Percolation. "Filtration," says the author, "is the passing of a liquid through a solid, with the view of the solid separating something from the liquid; percolation is the same operation, with the view of the solid imparting something to the liquid." After this definition he proceeds to sketch the manner in which percolation may be applied; the precautions indispensable to success when operating on various substances; approved forms of apparatus and the importance of intelligent packing.

Probably the degree of attention to this last point accounts for the discrepancy of opinion entertained by experimenters as to the value of the process.

Turning to quite a different subject, the unguentum hydrargyri nitratis, one is relieved to find that that interminable question is not made an excuse for an essay, and we thoroughly agree with the writer when he states:—"There has been much stated about the difficulty of making a good nitrate of mercury ointment, and a great number of formulæ have been suggested. There need not, however, be any deviation either from the ingredients or the mode of operating directed in the British Pharmacopœia." When once official authority had sanctioned the proportions of mercury and nitric acid which had long been used in private laboratories, no further change was requisite.

Following Mr. Proctor behind the dispensing counter, those who themselves are practically versed in compounding medicines will recognize in the lecturer a safe guide for others who are anxious to learn the art and mystery of dispensing.

We miss indeed certains excellent excipients for pill masses of difficult combination, and each pharmacist of any standing would be able to suggest minor improvements; but a general exposition of the subject is given, sufficient to direct the student in all material points; and we have no intention of blaming the writer of a book for being unable to supply that peculiar knowledge which personal and actual manipulation can alone supply.

The same remark applies to the series of autograph prescriptions, which gave so distinct a character to these lectures on their first appearance.

The selection (thirty-two in number) is soon exhausted, and may be taken rather as a sign-post to indicate the path to the traveller than as a guide-book to direct his steps. The facsimiles are now relegated to the end of the volume at the conclusion of the text in order that the student may not be tempted to read the commentary

* London: J, and A. Churchill. Demy 8vo. Pp. i.–xvi., 1–493. With 32 plates. 12s.

before having made a fair effort to decipher the handwriting of the formulæ.

In example No. 28 a doubt rests on the reading of an ingredient which looks much like infus. diosmæ. It was so read by Mr. Proctor:—"I felt no hesitation in reading the infusion as diosma, though the patient said it was not the same as he had previously. Infus. quassiæ seems next in order of probability." Since the appearance of this facsimile several pharmacists in Buxton assured the author that they were familiar with the handwriting and the custom of the writer, and that the infusion was undoubtedly quassia. We felt, in 1873, no more hesitation than Mr. Proctor; and we would venture to express regret that a member of the profession should have the custom to write one thing and to mean another.

With this brief notice we must leave the lectures on practical pharmacy, stating only that the pharmacy of special drugs has been considerably enlarged, and that there is a new chapter entitled "Supplementary Notes on Pharmaceutical Testing.

We cordially commend the volume, and consider it indispensable to the rising pharmacist. It is now ten years since Mr. Proctor came before the public as the author of a treatise which was then most favourably received, and the present issue bears marks throughout of the maturer judgment and larger experience of the author.

CHEMISTRY: GENERAL, MEDICAL, AND PHARMACEUTICAL, INCLUDING THE CHEMISTRY OF THE U.S. PHARMACOPŒIA. By JOHN ATTFIELD, F.R.S., etc.* Tenth Edition. Specially Revised by the Author for America.

This Manual of the general principles of chemical science and their applications in medicine and pharmacy is too well known in this country to need any description or criticism. The work is almost as popular in the United States, where indeed it probably is more widely used by pharmaceutical students than any other text-book on chemistry. The present is, we believe, the fourth edition that has been prepared with special reference to the United States Pharmacopœia, and has been thoroughly revised so as to cover the widely extended area and the altered conditions of the last edition of that work. Although the typographical arrangemeet is not, in our opinion, so hel; ful to the eye as that in the English edition, in respect to the paper, printing and binding, the American book is far superior, and reflects especial credit upon the publishers.

Correspondence.

⁂ *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE PHARMACEUTICAL SOCIETY.

Sir,—I have read, with feelings of amazement almost, the letter in last week's Journal on the above subject, signed "W. Wilkinson," and I should like to say a few words in reply. I cannot believe that Mr. Wilkinson will be very much gratified at seeing his strong effusion in print, notwithstanding that he expresses a wish that it should be printed. Surely he might be a little more charitable in his mode of expressing his "disgust," for, as you say, such strong language as he uses only tends to minimize the efficiency of the Pharmaceutical Society as a representative body. I am quite of the opinion that the registered chemist, in however small a way of business, should be on an equality with men in a larger way, and that no co-operative store should be allowed to deal in poisons.

But I think if instead of writing so strongly Mr. Wilkinson would show a little more loyalty to the Pharmaceutical Society, to which I presume he belongs, and, if he chooses, only vote for those members of the Council who pledge themselves to use their influence to restrain co-operative stores from dealing in poisons at all, he would be much more likely to gain the sympathy of his brother chemists. I trust some one more able than myself will reply to Mr. Wilkinson, but I hope he will forgive me if I advise him to be more considerate in his denunciations and just in his criticisms, and also lend a helping hand at any time he can do so to the Society; he will thus be far more likely to further the objects of the Pharmaceutical Society and the interests of pharmacy, which I trust he has at heart.

Stoke Ferry. W. H. NEWSAM.

Sir,—Mr. W. Wilkinson is scarcely fair to the Pharmaceutical Society. Surely it is not their fault if the House of Lords pronounced an insane decision *re* "limited companies," a decision that may be law, but assuredly is not common sense, and, if legal, the state of the law cries loudly for alteration.

Certainly the remarks about juries, however, seem remarkably tame! Why go cap in hand, when the law for once is distinctly on the pharmaceutical chemists' side.

Again, *re* sale of poisons. Why should not every chemist adhere strictly to the letter of the law, and then sell in accordance with it, and resent the expression of every insulting coroner, who demands, as is not unusual, more caution than the law compels? This might help in passing more wholesome and stringent protective laws.

It is useless for Mr. W. Wilkinson to clamour for protection for chemists direct. It can only be obtained indirectly by pleading and proving the necessity for the safety of the public.

Does Mr. W. Wilkinson, moreover, wish the "poor beggar" to compete with him without qualification?

A CHEMIST.

Sir,—I do not quite perceive which you consider the "weakest link of the chain" in my letter, nor what you mean by its serving "to illustrate one of the influences which tend to minimize the efficiency of the Pharmaceutical Society as a representative body," unless you agree with what I have written.

I can only say that it was the expression of a feeling that prevails very widely both amongst the members and the trade outside, and could you read the expressions of sympathy and approval I have received since its publication you might perhaps come round to the opinion that the efficiency of the Pharmaceutical Society would be very much increased by a more vigorous policy.

Cheetham Hill, Manchester. W. WILKINSON.

"*Detective*."—In order to make your caution of any service our statements would have to be more precise than we could venture to make them with our present knowledge of the facts. In this and all similar cases application of the adage "*caveat emptor*" is the only real safeguard.

T. and T.—The gelatine capping is made by adding to seven pounds of light coloured glue ten ounces of glycerine and three pints of water. When the glycerine and water have been absorbed by the glue the whole is placed in a water-bath and the pigment added. See papers in *Pharm. Journ.*, [2], vii., 448 and 511.

W. D.—We cannot advise you; consult your solicitors.

W. T. Frost.—Apply to the Secretary for a copy of the pamphlet 'Hints to Apprentices and Students.'

Fritz.—(1) Any person may extract teeth, but only a registered person can legally represent himself to be a dentist. (2) The labels approach the limits very closely, if they do not transgress. It would be better to submit them to the Inland Revenue authorities.

Mr. Ward is thanked for his communication.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Fletcher, Cruickshank, Corry, Pring, A. K. F., W. R. F., F. J. F., Dispenser.

ABSTRACT OF RULES IN REFERENCE TO VOTES AT THE ELECTIONS OF ANNUITANTS.

Annual Subscribers of—Half-a-crown are entitled at each election of Annuitants to ONE Vote.
Five Shillings ... ... TWO Votes.
Half-a-guinea ... ... FIVE Votes.
One Guinea ... ... TEN Votes.
And to increase in the same proportion.
Five Guineas are entitled to ... ... FIVE Votes for life.
Ten Guineas ... ... TEN Votes for life.
And to increase in the same proportion.

Should any Subscriber or Donor, or the widow of any Subscriber or Donor, become a Candidate for an annuity, such number of votes shall be placed to his or her credit, at the first succeeding election, as shall be represented by the whole amount of subscriptions or donations to the Benevolent Fund he or she (or, in the case of a widow, her husband) may have contributed.

Cheques and post office orders to be made payable to ELIAS BREMRIDGE.

FORM OF BEQUEST TO THE BENEVOLENT FUND.

"*I give and bequeath the sum of* *unto the* PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, *the same to be paid out of my pure personal estate, and to be applied for the purposes of the* BENEVOLENT FUND *of the said Society.*"

THE COMPOSITION OF POTASSÆ SULPHAS CUM SULPHURE.*

BY T. MABEN AND M. DECHAN.

Having found in the course of business that the potassæ sulphas cum sulphure of commerce varied considerably in character, our attention was directed to the preparation of the substance, and it subsequently occurred to us to ascertain its composition and, if possible, the causes of the variations therein. This very old remedy was at one time held in high estimation, but of late years it has fallen into disuse, save in its connection with the preparation of artificial Harrogate salts. So far as we know, its composition has never been systematically investigated, which is, however, hardly to be wondered at, seeing that the substance has only a limited application.

The directions for the preparation of pot. sulph. c. sulph. are as follows:—"Take equal parts of nitrate of potass and of sulphur and mix them thoroughly. Throw the mixture in small successive portions into a red hot crucible and when the deflagration is over and the salt has cooled, reduce it to powder and preserve it in well-closed bottles."† When prepared strictly in accordance with these directions, the salt obtained varies very little in composition, provided small quantities only are operated with; with large quantities considerable variation may be expected.

The colour of the substance ranges from yellowish-white to grey. The more yellow powder is obtained when the preparation is conducted throughout at a red heat, the colour varying slightly with the temperature. If a glazed crucible is employed and care taken in the preparation, the salt should always be more or less of a yellow colour.

Very different opinions have been expressed regarding its composition, but this is not at all surprising; considering the difficulty of obtaining specimens of the salt identical in every respect, it would be a matter for surprise had it been otherwise. One author states that the popular idea that it contains sulphate of potass with a little sulphur is, so far, incorrect; another, that it is composed of "sulphate mixed probably with some sulphite;" while a third thinks that in the reaction that takes place "sulphuret with sulphite, hyposulphite or sulphate are probably formed." Christison found that "sulphuretted hydrogen is not disengaged on a strong acid being added," while the late Mr. John Mackay‡ states that this gas was given off on the addition of water. Mr. Mackay's opinion was that the substance consists of sulphate and sulphuret of potash and free sulphur in the respective proportions of 55, 35 and 10.

It is more than probable, in consideration of these conflicting opinions, that the authorities cited have been describing, under the same name, salts in some respects quite distinct from each other, and our own experience strongly supports this conjecture.

We have met with specimens of the salt that did not give off appreciable quantities of sulphuretted hydrogen on the addition of a strong acid, while other specimens evolved an abundant supply of that offensive gas on being mixed with cream of tartar and water.

The cause of this variation is, as already stated, the degree of heat employed. Thus, we found that if the crucible is brought to a dull red heat before commencing operations, and this temperature maintained throughout, the percentage of sulphide is reduced to a minimum. If, on the other hand, the mixed powders are thrown into the crucible before red heat is attained, even though deflagration takes place, or if the heat is withdrawn before the operation is complete, the proportion of sulphide is certain to be higher than in the former case. If prepared in small quantities there is no difficulty in having a compound practically free from sulphide, as the necessary temperature for this end can be well kept up, but with large quantities this is not possible.

It is quite easy, therefore, to account for the different results obtained by Christison and Mackay. The former would doubtless prepare only a small quantity, and that at a red heat according to the directions, while the latter operated with large quantities, and he expressly states that he began to throw in the mixture before red heat was attained, one of his reasons for so doing being that the loss was greater at the higher temperature. We have verified this statement, having found that from 40 to 45 per cent. of finished product can be obtained according to the temperature employed.

We have analysed the seven samples which are on the table, the detailed results being as follows:—

	1	2	3	4		6	7
Potassic sulphate . .	95·9	92·5	97·75	96·5	97·0	96·0	97·5
Potassic sulphide . .	0·6	1·2	0·4	0·1	0·7	0·8	0·6
Free sulphur	1·0	0·4	0·5	0·5	0·4	0·5	Trace
Insoluble matter . .	0·5	4·1	0·5	1·5	0·6	0·5	0·25
Moisture and loss . .	2·0	1·8	0·85	1·4	1·3	2·2	1·65
	100·0	100·0	100·00	100·0	100·0	100·0	100·00

Nos. 1, 2, 3 and 6 were bought in the usual course of business; Nos. 4, 5 and 7 were prepared by ourselves. No. 4 was prepared in very small quantity and at red heat; No. 7 was also prepared at red heat, but in larger quantity, and No. 5 was prepared at the lowest temperature at which deflagration took place. No. 2 contains a trace of sulphite from which the others are free. None of the samples contain hyposulphite. The insoluble matter in No. 2 was chiefly iron; the salt had evidently been prepared in an iron crucible. No. 4 was prepared in a Hessian crucible, which may account for the larger proportion of insoluble matter in it than in Nos. 5 and 7.

The sulphate was estimated with barium in the usual way. The sulphide, being present in rather small quantities for weighing, was estimated by means of sodic nitroprusside, the colour reaction of which is exceedingly delicate, though, without special precautions being taken, it is difficult to obtain reliable results by means of this reagent. The sulphide was present as one of the polysulphides, probably the pentasulphide. Owing to the intense heat required in the preparation, it is almost impossible for hyposulphite to be formed, while with the nitric acid as an additional oxidizer, the presence of sulphite other than as traces can hardly be expected.

It will be noticed that while all the samples contain sulphide, No. 2 alone can be said to have more than a trace. It is perfectly possible, however, that the salt may be prepared under such conditions that it will contain a larger percentage of the sulphide should such be desired. So far as we can judge all the samples on the table have been carefully pre-

† 'Edin. Pharm.,' 1841.

‡ *Pharm. Journ.*, [1], i., p. 319.

pared according to the directions already quoted, but we have met with those regarding which this could not be said.

The question now arises, ought pot. sulph. c. sulph. to contain sulphide or not when used to make Harrogate salts? It is well known that this preparation has very little relation to the Harrogate mineral water, and, but for the sulphurous odour, would bear no resemblance whatever to it. As, however, Harrogate salts is a standard article, and in very great request as a family remedy, it is of importance that its composition should be as uniform as possible. Some might argue that since Harrogate water gives off sulphuretted hydrogen, so also ought a solution of Harrogate salts; while others might very fairly hold that the artificial compound has no relation to, and whatever may have been the original idea, it ought not now to be regarded as a substitute for, Harrogate water.

If the general opinion of the trade was in favour of a compound containing no sulphide the wholesale houses would soon satisfy the demand, and *vice versâ*. At present each maker will doubtless have his own standard, and unless the substance be always got from the same source its character is sure to vary. Indeed, as we have pointed out, variation may even occur to a considerable extent in different samples supplied by the same house. It is with the view of directing attention to this, the effects of which had frequently given us annoyance before we recognized its cause, that we have placed on record the results of our investigation.

PIPITZAHOIC ACID OR VEGETABLE GOLD.

BY THOMAS GREENISH, F.C.S.

At the annual general meeting of the German Apotheker Verein, which took place last autumn (1883), in Wiesbaden, there was exhibited by Herr Vigener, of Bieberich, a sample of a Mexican drug, rad. pereziæ, called by the natives "raiz del pipitzahuac." This root, but little known in Europe, has long been medicinally employed in Mexico, where it is much esteemed by the natives as an agreeable and energetic purgative. Prepared with brandy, it is considered by them a universal remedy for all diseases, including cholera. It is chiefly found in North Mexico in the valley of Tenancingo in the province of Toluca. Together with the root there were shown some samples of pipitzahoic acid which had been extracted from it in a more or less impure condition, varying with the solvents used—one specimen being in fine flakes, the result of subsequent sublimation, and of a brilliant golden yellow colour, hence the name "vegetable gold" applied to this product of the root.

The first notice of this drug in European scientific literature is in 1855, when Dr. Schaffner, a young German pharmacist, obtained of Dr. Leopold Rio de la Loxa, Professor of Chemistry and Pharmacy in Mexico, a sample of the pipitzahoic acid isolated first by him in a crude state by the dry distillation of the root, and also a second specimen of the acid, one of greater purity, the result of extraction with alcohol and subsequent crystallization.

A small quantity of this acid was forwarded to Professor Liebig for analysis, and he handed it over to his assistant, Weld. A notice of this analysis will be found in the *Annalen der Chemie und Pharmacie*, 1855. The sample was found to be soluble in spirit, but not completely soluble in absolute alcohol or ether, and almost insoluble in water; but as the pure acid is soluble in absolute alcohol and ether, Weld concluded that the sample was contaminated with some foreign resinous substance. On the evaporation of the alcoholic solution the pipitzahoic acid crystallized in leafy tufts and from the ethereal solution in small shining oblique-rhombic tabular crystals. The acid, of a golden colour, remains unaltered in the air; it is almost insoluble in water, easily soluble in alcohol and in ether, from which it is precipitated by water in a voluminous yellow mass. It melts at 100° C. to a red fluid which on cooling assumes a crystalline form. At a temperature only a little above 100° C. it volatilizes without decomposition and condenses in golden yellow leaves. The small quantity of acid at the disposal of Weld did not allow of his making further experiments, but the chemical formula he gives as $C_{30}H_{20}O_6$.

From 1855 to 1876 the literature of chemistry, pharmacy or medicine makes no mention of this substance, but Mr. J. R. Jackson, in his report on the Chemical and Pharmaceutical Products in the Philadelphia Exhibition, 1876, referring to the Mexican exhibits says, "Amongst chemical products are first pipitzahoic acid and pipitzahuina, the extracts of a composite plant variously stated by different writers as, *Perezia fruticosa*, *Acourtia rigidia*, *Dumerilia alamani*, and in the Mexican catalogue as trixis pipitzahoac. The organic compounds extracted from this plant are described as interesting not only because of their novelty but of their prospects of future usefulness. Pipitzahoic acid is of a 'brilliant golden colour and of a soft silky texture, being contained either in an amorphous state or crystallized in small prisms and laminæ.' At present pipitzahoic acid is employed in medicine as a drastic purgative; it can also be used as a colouring matter."

It is remarkable that a substance so interesting as this acid should have received so little attention; but this may probably be due to the difficulty experienced in procuring a supply of the raw material. Yet the fact of it being extensively used in Mexico as a domestic purgative points to the probability of its existence there in some quantity, and within easy reach of the natives requiring it.

The method adopted by Herr Vigener to obtain the acid which he exhibited was making a tincture with 1 part of the powdered root and 5 parts of nearly absolute alcohol; to the tincture thus prepared, boiling water was added to a point of dilution when the acid separated from the fluid in crystalline scales; by repeated solution and recrystallization it was obtained in a tolerably pure state. All his samples, however, the results of extraction by different menstrua, on being sublimed, left more or less of a tarry residue. The sublimed product had also a trace of it, but he purposed experimenting further in this direction, and hoped by repeated sublimation to obtain an acid in a state of greater purity and free from the contamination. The fine purple colour which this acid yields when mixed with alkalies or alkaline carbonates induced Herr Vigener to think that in chemical investigation there was a future for this substance as a colour indicator.

Pipitzahoic acid appears to be an anthraquinone derivative, but differs from every other through the property it possesses of subliming without decomposition at a very low temperature, even that of a water-bath, and subsequently condensing in golden crystals.

Through the courtesy of Herr Vigener I was presented with a few of the roots and a very small quantity of his sublimed acid, and on my return to England it occurred to me that a histological investigation embodying the chief characters of the root without needless detail would possess some interest, more especially as the pipitzahoic acid is allied to and possesses some features in common with chrysophanic acid.

Botanically, the Perezia plant belongs to Mutisiaceæ, a subdivision of the Labiatifloræ (Compositæ); it has no representative in Europe, but is found, with allied plants, in Central America and Mexico.

The roots, as furnished me, were in pieces of from 8–10 cm. long and 2 mm. thick, externally of a brown or reddish-brown colour, more or less furrowed longitudinally on the surface, apparently through the shrinking of the root in the process of drying; its taste was decidedly bitter, leaving a pungency on the tongue which remained after the bitterness had passed off, and this pungency was somewhat persistent.

In a transverse section of the root the yellow spots of pipitzahoic acid were visible to the naked eye, and more distinctly seen in their relation to the other parts when the section was slightly magnified with a lens, as in fig. 1. A segment of the

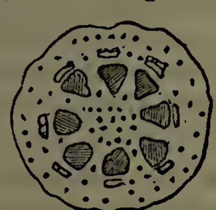

Fig. 1. Section of root, slightly magnified.

same section more highly magnified is seen in fig. 2.

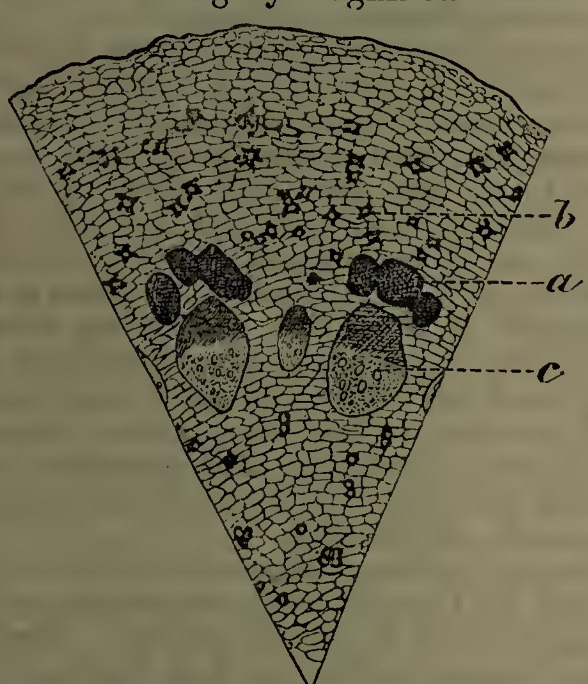

Fig. 2. Transverse section; *a*, pipitzahoic acid; *b*, stone cell; *c*, vascular bundle.

The outer cortical layer consists of a double row of thickened tabular cells, tangentially disposed and deeply coloured; this is followed by a layer, several cells deep, of collenchymatous tissue passing inward to the fundamental parenchyma of the root. *a* represents the pipitzahoic acid in its secreting cells, in groups of from three to five; the acid is in yellow lumps of a crystalline structure. These depositories of the acid, striking in the entire section, are arranged in a circle and correspond to the fibrovascular bundles indicated by *c*. The stellate spots *b* scattered throughout the fundamental tissue from the collenchyma to the centre of the root are due to certain cells only of the tissue becoming thickened by secondary deposit, and converted into sclerenchymatous or stone cells with laminated structure, the intercellular spaces being filled with a dark coloured deposit. These cells are found mostly single, but occasionally in groups of two, three or more. Fig. 3 is a longitudinal section showing, in

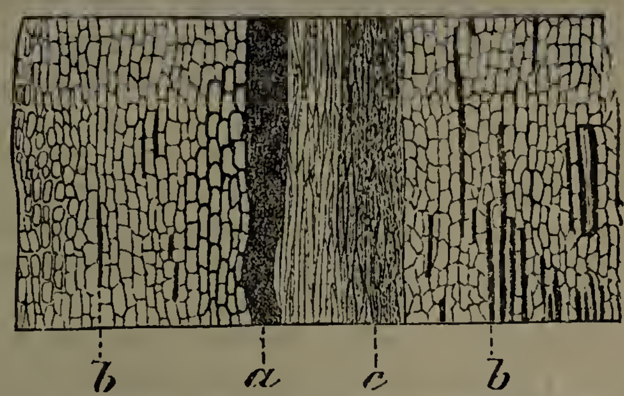

Fig. 3. Longitudinal section.—*a*, pipitzahoic acid *b*, stone-cell; *c*, vascular bundle.

addition to the relative positions of the cells referred to, the more characteristic constituents of the root as pipitzahoic acid, and the dark deposit around the stone cell traversing the length of the root. Fig. 4

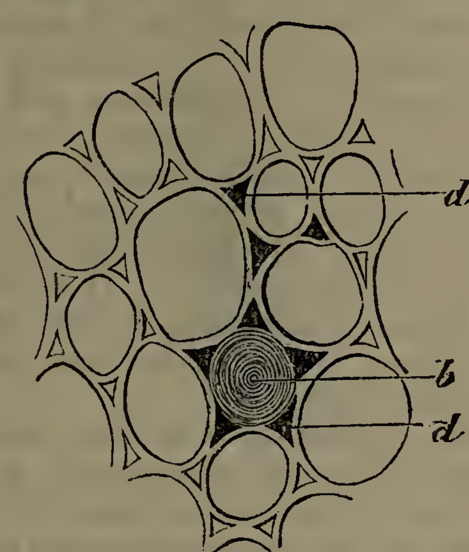

Fig. 4. Transverse section, showing a stone-cell.—*b*, stone-cell; *d*, intercellular secretion or deposit.

is a still further enlargement of the stellate spots as seen in fig. 2, the intercellular dark deposits with and without the presence of a stone cell are depicted in this drawing. Fig. 5 is a longitudinal section

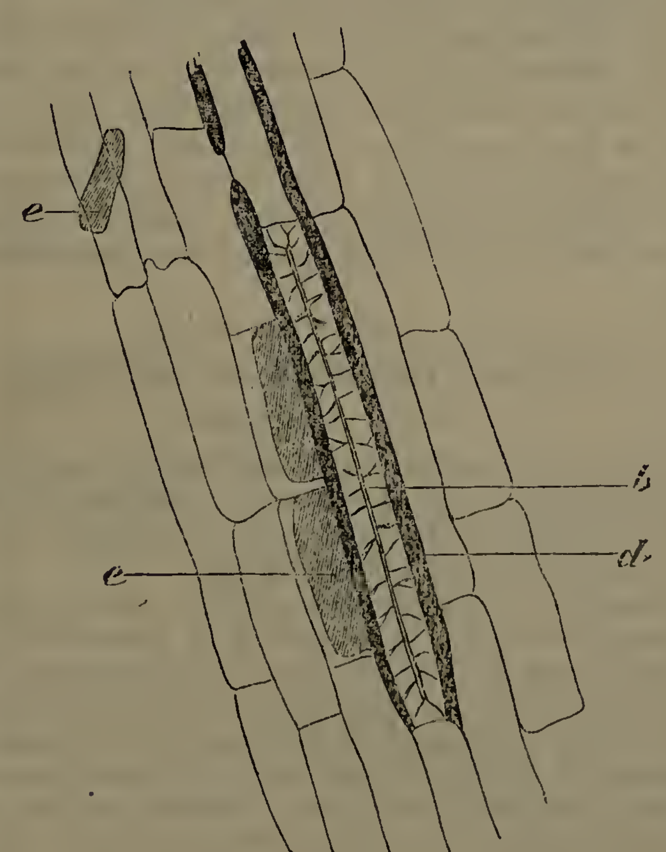

Fig. 5. Longitudinal section, showing a stone-cell. *b*, stone-cell; *d*, intercelluar secretion; *e*, inulin.

showing a stone cell in its entire length and surrounded throughout by the deposit just referred to. Most of the parenchymatous cells contain grains of inulin, which are seen at *e*, *Perezia* being one of the Compositæ, and containing inulin as the equivalent of starch present in the plants of other orders.

This brief account of the microscopical structure of the Perezia root will, with the drawings, serve to make the more salient features in its histology intelligible. The quantity of root placed at my disposal was only 2 grammes, and that of acid 0·33 of a gramme; it must, therefore, be obvious that few experiments beyond those afforded by micro-chemistry could be undertaken.

A transverse section of the root in which the lumps of pipitzahoic acid were visible was subjected to micro-sublimation on a microscopic glass slide, and at a little over 100° C. the acid sublimed on the cover-glass in yellow crystals. An alcoholic tincture of the root, yellow from solution of the acid, brought into contact with a dilute solution of caustic alkali or alkaline carbonate, developed that fine purple colour which induced Herr Vigener to suggest a probable future for the acid as a colour indicator in chemical investigations. The tincture on evaporation yielded crystals of pipitzahoic acid.

I was unable to satisfy myself as to the character of the intercellular dark deposit *d*. It was not affected by alcohol, ether, benzol, chloroform or turpentine; neither did caustic alkali dissolve it; it was decomposed by nitric acid. If from the negative results of these experiments I may be allowed to offer an opinion, it would be that the deposit in question is dried latex.

When the pipitzahoic acid first came under my notice it occurred to me as probable that its formation might be due to a degradation of tissue and a rearrangement of its elements similar to that which takes place in araroba or goa powder; but a careful anatomical investigation does not support that view. It appears to be a true secretion in certain cells occupying the same relative position throughout the root, and unaccompanied by any of that breaking down of the surrounding cells so marked in the microscopical investigation of araroba.

The *Perezia* may prove a valuable medicinal plant, but to determine that point there are yet wanting those careful therapeutic investigations which should precede the appearance in general practice of any new drug, a series of well conducted experiments which very few seem capable of conducting, and for the results of which still fewer have the patience to wait.

DIASTATIC FERMENT OF BACTERIA.*

BY J. WORTMANN.

Recent investigations have conclusively established the universal occurrence of diastatic ferments in different parts of plants, and have thrown a new light on the processes of nutrition and fermentation.

According to earlier observations, the presence of diastase in the plant was limited to germinating wheat or barley, and knowledge in regard of its wider diffusion has been advanced by the recent works of Gorup-Besanez, Will, Kranch, and especially Baranetzky. The researches of Musculus, E. Schulze, O'Sullivan, and others, have afforded an insight into the quantitative relations and the modifying external factors of temperature and acidity concerned in the action of diastase in the transformation of starch into glucose.

Having in view the action of bacteria as causes of putrefaction or fermentation, in which the destruction of the putrescible or fermentescible body is accomplished by the appropriation for the purpose of nutrition by the bacteria of constituent nitrogen or carbon, the question may be asked—Can bacteria also obtain their carbon from starch, just as by the researches of Pasteur and Cohn they have been proved to be capable of obtaining it, not only from sugar but from ammonium tartrate? Are bacteria, by the secretion of a starch-transforming ferment analogous to diastase, or in any other but not clearly defined way, capable of transforming starch into soluble, diffusible, and nutrient combinations? Notwithstanding the numerous investigations into the chemical and physiological relations of bacteria, very little has been made out in regard to their action on starch—a circumstance from which it may be presumed that the solution of starch by bacteria can be effected only in certain instances. In his work, 'Ueber die niederen Pilze,' Naegeli refers to the secretion by these organisms of a special energetic ferment capable of changing milk-sugar into fermentescible sugar, starch and cellulose into glucose, and of dissolving coagulated albumin and other albuminates, and Sachsse alludes to the circumstance of starch solution undergoing no change so long as it is protected from the influence of organic germs by which otherwise it quickly undergoes transformation.

Some experiments, made by the author in the summer of 1881 with milky juices, led him to believe that certain appearances of corrosion exhibited by the starch granules present must be due to the action of bacteria. The result of further precise experiments, undertaken to decide this point, led to the conclusion that bacteria are capable of drawing their supply of carbon from starch, and that the appearances of solution or corrosion exhibited by the solid starch granules are identical with those caused by the action of diastase or saliva.

The method used by the author was as follows:—To about 20 or 25 c.c. a mixture of inorganic salts (sodium chloride, magnesium sulphate, potassium nitrate, and acid ammonium phosphate) in equal proportions was added to the extent of 1 per cent. The same quantity of solid wheat-starch was then added, and the liquid then inoculated with one or two drops of a strongly bacterial solution, shaken, corked, and allowed to remain in a room at a temperature of 18° to 22°. [*Bacterium termo* was the predominating organism in the inoculating fluids employed.] In from five to seven days, the first signs of commencing corrosion of the starch grains become visible, the larger grains being the earliest attacked, and much later, when these have almost completely disappeared, the lesser granules are attacked.

In a second series of experiments soluble starch was substituted for the solid form, the progress of the reaction being watched by the aid of iodine. Samples taken from time to time exhibited at first the blue colour, then violet or dark red, passing to wine-red, and, finally, when the starch had disappeared, underwent no change.

As Baranetzky has shown, the starch granules of different kinds are acted on with very unequal rapidity by the diastatic ferments of plant juices, the strongest ferment of all—malt diastase—being well known to have no perceptible influence, even after long exposure, on solid potato-starch granules, whilst wheat and buckwheat are dissolved with facility.

Experiments were made with a view to ascertain whether the action of bacteria on starch was analogous; in these, wheat-starch grains are shown to be by far the most readily attacked by bacteria—in several instances having even completely disappeared before other sorts of starch were attacked. Differences were also noticed in regard to the times when palm-starch, canna-starch, turmeric-starch, and iris-starch were attacked, their degree of resistance being in the order given. Potato-

---

* From *Zeitschr. Physiol. Chem.*, vi, 287–329. Reprinted from the *Journal of the Chemical Society.*

starch alone resisted attack. When wheat-starch in the solid state was mixed with starch solution or with starch-paste, the solution became entirely (and the paste in greater part) changed before the solid granules were attacked.

With regard to this unequal power of resistance shown by different kinds of starch, the author concludes from his further observations, that the difference of rapidity with which a given kind is attacked and dissolved by a ferment is inversely proportional to its density, provided always that the granules in question are entire and uninjured by cracks or fissures. In the same way are explained the differences in point of time in which granules of the same kind are sometimes observed to undergo change accordingly as these are intact or otherwise.

The cause of potato-starch, or of bean-starch, and, even under certain conditions, wheaten starch resisting attack, in spite of the abundant presence of bacteria, is apparently to be sought for in the fact that other more easily accessible sources of carbon nutriment were also present, certain albuminoid constituents of the potato slices or of the beans employed affording this more readily than the starch granules, just as in the experiments, above cited, with wheaten starch solution and solid wheaten starch, the former was preferentially attacked; only after all, or at the least chief portion of the albuminoids present, had been used up was the starch in these cases attacked.

Experiments were also made with the same results in which, after Cohn, ammonium tartrate was employed along with starch as a nutrient medium for the bacteria, with the result that so long as even a trace of this salt was present with the starch, the latter was not attacked by bacteria in the slightest degree, but, on its disappearance, appearances of solution became at once visible in the starch granules. Another point was also established in the course of these experiments, that if air is excluded, no appearances of corrosion or solution of the starch granules are manifested.

Other researches were made to answer the problem as to whether the nature of this action of bacteria on starch was such that an unformed ferment analogous to diastase was secreted by those organisms to which the corrosive appearances may be ascribed, these being, as already stated, precisely similar to the resulting action of diastase itself.

That the starch in the process became changed in part to glucose was easily ascertained by testing with Fehling's solution, and a detailed series of experiments, made with a view to eliminating if possible the ferment itself, yielded evidence showing that bacteria possess the remarkable property of producing a starch-transforming ferment only when no source of carbon other than starch is at their disposal, and this ferment is incapable of changing albumin into peptone, just as in the case of diastase. It is well known that the pepsin of gastric juice acts only in an acid medium. The plant juices which possess a diastatic property exhibit likewise a more or less acid reaction, so that as Baranetzky assumes, the co-operation of an acid in the case of diastase is a necessary condition of its activity. The solutions in which starch in one or another form was submitted to the action of bacteria were always slightly acid, due to the presence of acid ammonium phosphate, and when the solutions were purposely made neutral, the process of starch transformations went on more slowly. Detmer some time since has shown that addition of small quantities of citric acid to a solution containing diastase, hastens its action on starch. The author's observations are in harmony with this, but in addition show that the process of starch transformation by bacteria is capable of going on in the absence of acid, and that the bacteria do not yield any acid in the process. The results of the author's researches may be briefly recapitulated.

1. Bacteria are capable of acting on starch, whether in the solid state, as paste, or in solution, in a manner analogous to diastase.

2. As in the case of diastase, different kinds of starch are attacked by bacteria with different degrees of rapidity.

3. The action of bacteria on starch is manifested only in the absence of other sources of carbon nutriment, and when access of air is not prevented.

4. The action of bacteria on starch is effected by a ferment secreted by them, and which, like diastase, is soluble in water, but precipitable by alcohol.

5. This ferment acts precisely as diastase in changing starch into a sugar capable of reducing cupric oxide, but is not possessed of peptonizing properties.

6. The ferment itself is also capable of acting on starch in the absence of oxygen.

7. The ferment is secreted by the bacteria also in neutral solution of starch, and exerts its influence under these conditions.

8. This influence is expedited in slightly acid solutions.

The author concludes his paper with speculations as to the conditions under which bacteria are capable of generating this amylolytic (diastatic) ferment, instead of the ordinary peptonizing one.

MEDICATED WATERS.*

BY JOSEPH W. ENGLAND, PH.G.

The U. S. Pharmacopœia of 1870, in the formulæ for these waters, gave in all cases, either one or the alternative of two processes. First: Distillation of the odorous part of the plant with water, after previous comminution and maceration if necessary; or, second: Trituration of the volatile oil of the plant with magnesium carbonate, the addition of distilled water and filtration.

During the process of "distillation" the water carries over with it in suspension the vapour of the oily product used and both are condensed in the receiver in separate layers. The oily portion is separated by suitable apparatus, leaving the water impregnated with its taste and fragrance. The fragrance is at first masked with a foreign odour that gradually disappears on exposure to air; leaving the true one, partially modified to one of finer quality, through the supposed presence of certain volatile acids and compound or mixed ethers. Distillation while admittedly the best in comparison with the present methods pursued, is to a great extent in the limited uses of most pharmacists impracticable for general employment. It requires for its successful exercise, the manufacture on a large scale, great care and skill on the part of its operators, and the use of vegetable products of quality seldom found in commerce to secure the best results. Its general application, therefore, is far from being a universal one.

The process of triturating the oil with magnesium carbonate is directed for the property possessed of reducing, mechanically, the size of the oily globules in order to present a greater surface to the solvent action of the water. The main objection to its use, rests upon the fact of its appreciable solubility in distilled water and to a still greater extent, when ordinary water containing in solution, as it usually does, carbonic oxide. The medicated waters thus made and holding in solution this alkaline-earth salt may, when prescribed with alkaloids, their salts or certain metallic oxides, precipitate them from solution on standing and possibly lead to grave and serious results. To overcome this defect the substitution of paper-pulp, chalk, pumice stone, or charcoal has been proposed. These, however, are poor expedients and all fail through their inherent lack of the necessary power of diffusion of the oily ingredient upon trituration. The advantages of the "trituration process" to the general pharmacist are so manifold that they scarcely need comment. The readiness of manufacture on a small scale, the short time necessary for its performance with results

* From the *American Journal of Pharmacy*, February, 1884.

equally satisfactory, except in a few isolated instances, and the cheapness of preparation, are a few of the points of value which yield it preference for general usage.

The late revision of the U. S. Pharmacopœia discards, entirely, the use of the "trituration process" and employs in its stead a method which consists, simply, in the distribution of the oil, in small portions at a time, upon cotton; picking the same apart after each addition until the whole is thoroughly impregnated with it, packing in a conical glass percolator and displacing with distilled water. The exceptions to this mode are bitter almond water, prepared by direct solution of the oil in water by agitation, and rose and orange flower waters made by distillation. A practical acquaintance with this process does not impress one with either its worth or general utility. Its supposed advantages are more than counterbalanced by the very unsatisfactory results arising from its use. In the first place when the oil is added to the cotton, no matter how faithfully its dissemination may be executed, a large proportion is necessarily lost upon the fingers in picking the fibres apart. Then when it is placed in the percolator, if packed too loose, the added water rushes through without dissolving any of the oil. If too tight, the process is impeded to such an extent that percolation becomes impossible. The right degree of packing is hard to obtain and when secured yields but little better results. As to the use of distilled water, very few follow the pharmacopœial directions in this particular. Without exceptions, all pharmacists with whom the author has conversed substitute ordinary water and claim in extenuation, that extreme purity of that liquid is unnecessary, and that they are perfectly justified in the replacement from the fact that distilled water is frequently of a musty, unpleasant odour, vapid and disagreeable taste, and as likely may contain metallic impurities from the uncertain, careless methods of commercial manufacture; further their efficiency is called into question from the physiological fact that distilled water is difficult of digestion and not as acceptable to irritable stomachs. These statements may be regarded as extreme, yet it must be admitted that the greatest efficiency of all medicines is desired, in a physiological sense as well as a pharmaceutical one. If the reasons advanced are tenable and do not arise from economic considerations they are certainly worthy of further notice. Certain it is that the products made by them, seem to give equal satisfaction with those made by standard authority. In whatever way we view the U.S. (1880) process, its wasteful and objectionable manipulations are so evident, that if the imperfections in the directions of the earlier Pharmacopœia (1870) were open to severe comment, those of the latter (1880) are doubly so by comparison.

As previously stated, the greater the subdivison of an oil, when brought in contact with an aqueous solvent, the larger the quantity that will necessarily be taken up in solution. As an aid to this fact and also their supposed insolubility, rests the adaptability of the bodies mentioned above as diffusive agents. Some of the objections to the use of magnesium carbonate and several of its proposed substitutes have already been noted. Upon trial I have found precipitated calcium carbonate to be preferable, mechanically, to the magnesium salt; yet it is open to the same adverse criticisms. Another possibly important objection to the use of alkaline earth carbonates, which has not been previously discussed, may reside in the fact of the presence of odorous volatile acids, ethers, etc., in the volatile oils used and the neutralization of those acids by the alkaline carbonates, to form neutral and inodorous bodies, which may or may not be soluble. This view is a plausible one when we consider the delicate chemical constitution of the oils in general, especially those containing the previously mentioned compounds. Upon this fact may be based the superiority of "distilled" over "triturated" waters, as in distillation the water is impregnated with the oil direct and unchanged; while in trituration, if performed with carbonates, some changes undoubtedly ensue, since the products from the latter process are of less fine qualities than those of the former; although both may be made from the same oil. It is absolutely necessary on this account, to use a body free from these objectionable features and one which has all the essential requisites in the greatest degree. After numerous trials I have found precipitated calcium phosphate to possess all the desired properties and to yield products that were in all respects the equal of those obtained by distillation.

This lime salt is a neutral, impalpable solid, wholly insoluble in water, neutral or carbonated, and when used permits filtration much more readily and effectively than any other medium. In diffusive power it is fully the equal of any of the bodies previously mentioned; leaving nothing to be desired. Before its use, although generally very pure, tests should be always applied to determine that fact. It should be wholly soluble in dilute hydrochloric acid without effervescence (absence of carbonates). Its washings with distilled water should yield no opalescence or precipitate with test solutions of silver nitrate (absence of chlorides), barium chloride (absence of sulphates) or ammonium oxalate (absence of soluble lime salts).

When diffusive agents are used, they require long and persistent trituration with the oil to effect thorough and minute subdivision. In order to promote this diffusion, a plan of diluting the oil with a small quantity of alcohol was tried and found to work admirably. The presumed presence of alcohol in medicated waters thus made, has no foundation in fact, if the directions in the general formula, hereinafter given, are followed, as the rubbing to dryness necessarily volatilizes the whole of it.

General Formula. — Triturate, in a mortar of broad surface, the oil dissolved in the alcohol, with the precipitated calcium phosphate, until a dry powder is secured and all the alcohol has volatilized, then add the water in small portions at a time, stirring after each addition, until the intended quantity to be made is completed. Lastly, filter; returning to the filter the first portions, if cloudy."

The following formulæ, under each heading, are expressed in two ways. One according to the method of the U. S. P. of 1870, and the other like that of the U. S. P. of 1880.

Aqua Anethi, Br.—Oil of dill, $\frac{1}{2}$ a fluid drachm; alcohol, $1\frac{1}{2}$ fluid drachms; precipitated calcium phosphate, 2 drachms; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, oil of dill, 2 parts; alcohol, 6 parts; precipitated calcium phosphate, 8 parts; distilled water, a sufficient quantity to make the finished product weigh 1000 parts.

Aqua Anisi, U. S.—Oil of anise, $\frac{1}{2}$ a fluid drachm; alcohol, $1\frac{1}{2}$ fluid drachms; precipitated calcium phosphate, 2 drachms; distilled water a sufficient quantity to make the finished product measure 2 pints. Or, oil of anise, 2 parts; alcohol, 6 parts; precipitated calcium phosphate, 8 parts; distilled water, a sufficient quantity to make the finished product weigh 1000 parts.

Aqua Aurantii Florum, U. S.—Oil of neroli (Bigarade), 12 minims; alcohol, $1\frac{1}{2}$ fluid drachms; precipitated calcium phosphate, 2 drachms; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, oil of neroli (Bigarade), 2 parts; alcohol, 15 parts; precipitated calcium phosphate, 20 parts; distilled water, a sufficient quantity to make the finished product weigh 2500 parts.

Aqua Amygdalæ Amaræ, U. S.—Oil of bitter almonds, 15 minims; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, oil of bitter almonds, 1 part; distilled water, a sufficient quantity to make the finished product weigh 1000 parts. Dissolve the oil directly in the water by agitation. Since 1 part of the oil is soluble in 300 parts of water, no further directions are necessary.

Aqua Camphoræ, U. S.—Camphor, 2 drachms; alcohol, 1½ fluid drachms, precipitated calcium phosphate, 4 drachms; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, camphor, 8 parts; alcohol, 6 parts; precipitated calcium phosphate, 15 parts; distilled water, a sufficient quantity to make the finished product weigh 1000 parts. Reduce the camphor in a mortar to a thin, smooth paste with the alcohol, add the precipitated calcium phosphate, and proceed as in general formula.

Aqua Cinnamomi, U. S.—Oil of cinnamon (Ceylon), ½ a fluid drachm; alcohol, 1½ fluid drachms; precipitated calcium phosphate, 2 drachms; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, oil of cinnamon (Ceylon), 2 parts; alcohol, 6 parts; precipitated calcium phosphate, 8 parts; distilled water, a sufficient quantity to make the finished product weigh 1000 parts.

Aqua Fœniculi, U. S.—Oil of fennel, ½ a fluid drachm; alcohol, 1½ fluid drachms; precipitated calcium phosphate, 2 drachms; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, oil of fennel, 2 parts; alcohol, 6 parts; precipitated calcium phosphate, 8 parts; distilled water, a sufficient quantity to make the finished product weigh 1000 parts.

Aqua Menthæ Piperitæ, U. S.—Oil of peppermint, ½ a fluid drachm; alcohol, 1½ fluid drachms; precipitated calcium phosphate, 2 drachms; distilled water a sufficient quantity to make the finished product measure 2 pints. Or, oil of peppermint, 2 parts; alcohol, 6 parts; precipitated calcium phosphate, 8 parts; distilled water, a sufficient quantity to make the finished product weigh 1000 parts.

Aqua Menthæ Viridis, U. S.—Oil of spearmint, ½ a fluid drachm; alcohol, 1½ fluid drachms; precipitated calcium phosphate, 2 drachms; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, oil of spearmint, 2 parts; alcohol, 6 parts; precipitated calcium phosphate, 8 parts; distilled water, a sufficient quantity to make the finished product weigh 1000 parts.

Aqua Pimentæ, Br.—Oil of allspice, ½ a fluid drachm; alcohol, 1½ fluid drachms; precipitated calcium phosphate, 2 drachms; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, oil of allspice, 2 parts; alcohol, 6 parts; precipitated calcium phosphate, 8 parts; distilled water, a sufficient quantity to make the finished product weigh 1000 parts.

Aqua Rosæ, U. S.—Oil of rose, 6 minims; alcohol, 1 fluid drachm; precipitated calcium phosphate, 2 drachms; distilled water, a sufficient quantity to make the finished product measure 2 pints. Or, oil of rose, 2 parts; alcohol, 30 parts; precipitated calcium phosphate, 40 parts; distilled water, a sufficient quantity to make the finished product weigh 5000 parts.

In conclusion, the author, in advocating the adoption of the preceding formulæ would say that any means used to insure success, are always secondary in importance to the quality of the materials used. No process, however good in itself, can hope to remedy defects in the qualities of its ingredients, or the hasty, careless manipulations of its operators. With these guarded against, there need be no disappointment in the results obtained.

AMERICAN DRUGS.*

BY J. MOELLER,

Botanist and Microscopist of the Imperial Forest Institute, Mariabrunn, near Vienna.

(*Continued from page* 565.)

4. HERBA MONARDÆ FISTULOSÆ (WILD BERGAMOT, HORSEMINT).

The coarsely-cut dried leaves gathered when the plant is in bloom. The square often violet-tinted stem is almost bare, except that it is quite hairy and somewhat swollen at the points whence the leaves proceed in pairs. These (Fig. 6*a*) are approximately oviform, somewhat pointed, rounded at the base, short-stemmed, coarsely

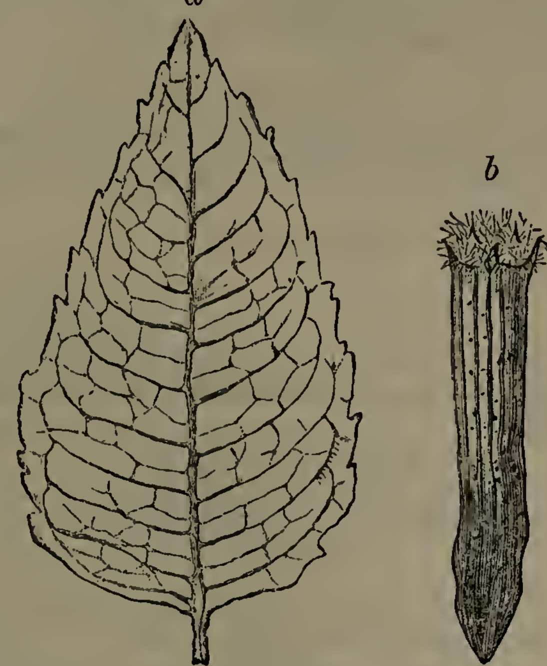

Fig. 6.

indentated at the edge, 5 cm. long, 3 cm. broad (those around the flowers being smaller, narrower and contracted towards the stem), with prominent middle and secondary nerves, the latter anastomosing towards the border. The leaves are rather smooth on both sides. The microscope, however, shows that these leaves are densely covered with small hairs, mostly but ·05 mm. in length, and consisting of but a single cell (Fig. 7)

Fig. 7.

highly interspersed with larger ones, particularly towards the edges, where they often consist of many cells. The scattered spots prove to be indentations in which the characteristic oil glands of the labiatæ are to be met with on their short broad stems. The flowers are arranged in dense pseudo verticils in the axils of the leaves, and are encircled by a thick-leaved bristly border. The calyx is nearly a centimetre in length, skinny, tubular, multiribbed, five-pronged, ciliated at the edge, naked and smooth on the inside, slightly hairy on the outside, displaying under the magnifying glass yellow glands (or glandular heads). The large double-lipped, flesh-coloured flowers are now but seldom found in the calyx.

The plant when dried has no specific odour; but when pulverized it has a penetrating aromatic odour, resembling peppermint. Its taste is strongly aromatic—almost free of bitterness.

Monarda fistulosa, L, is indigenous in the western states of the American Union. It is one of the plants most frequently met with in the territories of Montana and Dakota. It is nearest akin with the rosemary family. It is now about three years since wild bergamot (called also horsemint) was first applied as a curative. It was resorted to in cases of intermittent fever instead of quinine.

Dr. Woodward's (*Ther. Gaz.*, 1880, p. 224) reports of his experiments are as follows:—"I found that a drachm of the fluid extract every three hours, from the time of the height of the fever to the end of the attack, or

* Reprinted from the *Therapeutic Gazette.*

until a prickling sensation is felt throughout the body, or profuse sweating sets in, is the most appropriate dose for adults. In cases of simple intermittent fever, without any complications, this remedy has never disappointed my expectations, and I prefer it to quinine or any other febrifuge."

Dr. Woodward, however, does not undertake to call monarda an infallible specific for fevers, but maintains that it is well worthy of the careful notice of the medical profession.

THE USE OF LITMUS, METHYL ORANGE, PHENACETOLIN AND PHENOLPHTHALEIN AS INDICATORS.*

BY ROBERT T. THOMSON.

(*Continued from p. 672.*)

Table III.

Determination of ammonia existing as hydrate.

Ammonia (NH_3) employed for each test . . ·547 gram.

Name of Indicator.	C.C. of Normal Acid consumed.	Grams of NH_3 obtained.
Litmus	32·4	·550
Methyl orange .	32·4	·550
Phenacetolin . .	32·4	·550
Phenolphthaleïn .	31·5—31·4	·535—·533

Before writing the above, I had not met with any mention of phenolphthaleïn as an indicator for the estimation of ammonia, but, quite recently, it has been recommended for this purpose by Richter, in a paper on a "New Volumetric Determination of Potassium Bichromate, and its use as a Standard for Caustic Alkalies" (see *Chem. News*, xlvii., 19). The process he has devised may be thus briefly described. To the caustic soda, potash or ammonia solution which has been previously coloured with phenolphthaleïn, add standard dichromate of potassium till the reddish-yellow colour produced is changed to a full yellow. At this point the alkali is neutralized, a monochromate of the alkali or alkalies is formed, and the reddish tinge due to the presence of the phenolphthaleïn in the alkaline solution is discharged when the least excess of acid chromate is consumed. The quantities advised for use are such that the solution in which the titration has been accomplished should measure 150 or 200 c.c., and contain about 1 gram of the monochromate of potassium. A solution of this salt, of the strength mentioned, is to be used as a comparison in deciding at what point the end reaction occurs. Following these instructions as closely as possible, I prepared a decinormal solution of potassium bichromate (14·76 grams per litre), and, also, decinormal solutions of caustic soda, potash and ammonia, the alkali liquors being tested against decinormal sulphuric acid. Fifty c.c. of the soda solution were transferred to a beaker, diluted with 50 c.c. of water coloured with phenolphthaleïn, and the decinormal bichromate solution added from a burette. The fine red tint soon changed to reddish-yellow, which lost little or none of its intensity till it nearly reached the neutral point. The end-reaction was thus easily observed, especially when compared with the solution of monochromate of potssium of nearly the same strength as that operated upon. It must be carefully noted, however, that the change in colour is not instantaneous, as it is by titration with a mineral acid, so that when the test is nearly finished, a minute or two must be allowed to pass after each addition before coming to any conclusion as to whether the end-reaction has taken place. Otherwise a high result will be the consequence. The results of two tests were, that 50 and 50·1 c.c. of the decinormal bichromate were consumed, which are as near the truth as possible.

With regard to the determination of the potash, it is sufficient to mention that the results were substantially the same as those obtained with soda.

In estimating the ammonia in 50 c.c. of the decinormal solution of ammonia, the addition of the bichromate produced at first the reddish-yellow colour, which slowly disappeared on further addition, and gave place to the full yellow when 45·7 c.c. had been consumed in the one case, and 46 c.c. in the other. This gives a result so much below the truth, as to be equivalent to 8 per cent. of the whole ammonia present. From these results it is quite plain that Richter has not tested ammonia specially with phenolphthaleïn as indicator, but has simply assumed that it would act in precisely the same manner as potash and soda.

Table IV.

Comparison of results obtained in the estimation of alkalies by Richter's bichromate and the ordinary acid methods, phenolphthaleïn being the indicator.

Amount of soda used for each test . . ·1550 gram.
Do. potash do. . . ·2355 gram.
Do. ammonia do. . . ·0850 gram.

Name of Alkali determined.	C. C. of $\frac{N}{10}$ $K_2Cr_2O_7$ consumed.	Gram of Alkali obtained.	C.C. of $\frac{N}{10}$ acid consumed.	Gram of Alkali obtained.
Soda (Na_2O) . . .	50·1	·1553	50·1	·1553
Soda (Na_2O) . . .	50·0	·1550	50·1	·1553
Potash (K_2O) . . .	50·1	·2359	50·1	·2359
Potash (K_2O) . . .	50·2	·2363	50·0	·2355

Ammonia (NH_3) . .	45·7	·0777	46·9	·0797

V.—Determination of Alkalies existing as Carbonate and Bicarbonate.

It is not worth while going fully into the results of the tests made on this part of the subject. As almost all the noteworthy points have been already mentioned, I will just note a few necessary precautions. As is well known, litmus can be used in the direct estimation of soda and potash existing as carbonate or bicarbonate by an acid, but can only be applied to the determination of ammonia in that form when excess of acid is added, the solution boiled to expel carbonic acid, and titrated back with an alkali. The same remarks apply to phenacetolin.

Methyl orange can be employed equally well in the estimation of alkali in any of the alkaline carbonates, but special mention may be made of its application to the determination of ammonia in the commercial carbonate. This substance is a compound of bicarbonate and carbonate of ammonium, and when dissolved in water the latter of these salts takes up the elements of water and produces normal carbonate of ammonium. The sample tested did not contain any impurities except water, and 2·5 grams converted into chloride and dried at 100° C. showed ·725 gram of ammonia, while two experiments made with 2·5 grams, which consumed 43·1 and 43·05 c.c. of normal sulphuric acid, gave respectively ·732 and ·731 gram of ammonia.

Phenolphthaleïn, as stated before, cannot be used for the estimation of ammonia, and in the determination of soda and potash existing as carbonate or bicarbonate (the latter giving no colour with this indicator till decomposed by boiling), a somewhat tedious boiling is required unless excess of acid be added, the solution boiled and titrated back with caustic soda.

---

* Read before the Chemical Section of the Philosophical Society of Glasgow, January 22, 1883, and reprinted from the 'Proceedings.'

VI.—Behaviour of the Indicators with the Sulphates, Nitrates and Chlorides of the Alkalies.

Having considered the use of the indicators for the estimation of the alkalies when pure compounds are operated upon, we now come to the behaviour of the indicators with the common impurities present in commercial samples. This section, however, is chiefly concerned with the action (if any) of the neutral salts produced during titration. Litmus and phenacetolin are quite as delicate in presence of quantities of the sulphates, nitrates and chlorides of sodium, potassium and ammonium equivalent to 1·55 gram of soda (Na_2O) per 100 c.c. When these amounts of these salts were tested with the volume of methyl orange solution used in the foregoing experiments, it was found, as has been already stated, that about ·2 c.c. of normal acid was required to bring out the full pink colour as against ·05 c.c. when distilled water only was employed, although a distinct change was produced with ·05 c.c. in the former case. On the other hand, the delicacy of phenolphthaleïn is not affected by the salts of sodium and potassium mentioned above, but quantities of sulphate, nitrate and chloride of ammonium, equivalent to ·85 gram of ammonia per 100 c.c., required about 1·5 c.c. of normal caustic soda to produce even the faintest red colour, showing that ammonia and its salts must be carefully excluded when this indicator is made use of.

VII.—Effect of the Sulphites of the Alkalies.

A sample of ordinary normal sulphite of sodium was selected, tested for impurities, and the sulphurous acid, sulphuric acid, and soda determined to make certain that it was of the proper composition. This was found to be the case, and a solution was prepared of which 50 c.c. (the amount used for each test) contained 3·15 grams of sulphite of sodium. This is equal to 1·55 gram of soda (Na_2O).

Litmus.—On adding the normal acid to the portion tested with this indicator, the solution remained quite blue till about 12 c.c. had been added, but after that it became purple and slowly passed into the red. The end-reaction was observed by comparing with a solution containing the same quantity of litmus reddened. 24·9 c.c. were consumed, which is equal to ·771 gram of soda, or very nearly half that contained in the sulphite of sodium. When boiled, the colouring matter is destroyed.

Methyl orange.—In this case 25·1 c.c. of the normal acid were consumed, which is equal to ·778 gram of soda —a result slightly higher than that obtained by litmus, but still practically the same. The end-reaction was, unlike that of litmus, very sharp and decided.

Phenacetolin. — With phenacetolin the result was exactly the same as that procured with methyl orange; but, as in the case of litmus, the colour changed so gradually that the end-reaction was not very sharply defined.

Phenolphthleïn.—Sulphite of sodium is practically neutral to phenolphthaleïn, but, as has been shown, it is strongly alkaline to the other three indicators. Only ·2 c.c. of normal acid was necessary to discharge the red colour in the cold, but when boiled 4 c.c. were required. On cooling and titrating back, 3·8 c.c. of normal alkali were consumed; so that when this method is employed, the practical neutrality of sulphite of sodium may be depended upon, provided too much acid is not added before boiling. If a large excess of acid were used the boiling would expel sulphurous acid, and a high result would be the consequence.

It need only be added that potassium and ammonium sulphite act towards these indicators in the same way as the sodium compounds, except in the case of the ammonium salt with phenolphthaleïn, which cannot be used in presence of ammonium compounds.

Table V.

Results obtained in the titration of sodium sulphite with normal acid.

Amount of Na_2SO_3, used for each test. 3·15 grams.
Equal to Na_2O . . . . 1·55 grams.

Name of Indicator	C.C. Normal Acid consumed.	Grams Na_2O obtained.
Litmus	24·9	·772
Methyl orange	25·1	·778
Phenacetolin.	25·1	·778
Phenolphthaleïn (cold) .	·2	·006
Phenolphthaleïn (boiled) .	4·0	·124

VIII.—Effect of Thiosulphate of Sodium.

This salt, which is known better as the hyposulphite of soda, is perfectly neutral to litmus, methyl orange, phenacetolin and phenolphthaleïn.

IX.—Effect of Sulphide of Sodium.

To obtain pure normal sulphide of sodium a solution of sulphuretted hydrogen was prepared, the strength of which was determined by oxidization in an alkaline solution with peroxide of hydrogen, and precipitation with chloride of barium. Exactly enough hydrate of sodium was now added to form Na_2S, and the solution made up to such a volume that 50 c.c. (the quantity operated upon) contained ·284 grams of the sulphide.

Litmus.—When thoroughly boiled after each addition of acid to expel the sulphuretted hydrogen, an excellent result was obtained, 7·2 c.c. of normal acid being consumed. This is equal to ·280 grams of sulphide of sodium.

Methyl orange.—With this indicator the same number of c.c. of acid was consumed as with litmus. The liberated sulphuretted hydrogen had evidently no effect on the colour, as the end reaction was quite sharp. This has been pointed out by Lunge.

Phenacetolin behaves in much the same way as litmus, the boiling off of the sulphuretted hydrogen being necessary to the obtaining of a decided change in colour when the end of the experiment is reched. The result was the same as that obtained with litmus.

Phenolphthaleïn gave rise to the characteristic red colour with the sulphide of sodium; but this colour was discharged after the addition of 3·55 c.c. of normal sulphuric acid. This is practically equal to half of the sodium sulphide, and shows that the sodium hydrogen sulphide—which is formed by the combination of the normal sulphide with the liberated sulphuretted hydrogen—is neutral to phenolphthaleïn. On boiling the solution the red colour returned, and, altogether, 7·15 c.c. of the acid were consumed—the whole of the sodium sulphide being thus estimated.

Potassium and ammonium sulphides have exactly the same same effect as the sodium compound, always excluding phenolphthaleïn with regard to the ammonium salt.

Table VI.

Results obtained in the titration of sodium sulphide by normal acid.

Amount of Na_2S employed for each test . . ·284 gram.

Name of Indicator.	C.C of Normal Acid consumed.	Grams of Na_2S found.
Litmus	7·2	·280
Methyl orange	7·2	·280
Phenacetolin	7·2	·280
Phenolphthaleïn (cold) .	3·55	·138
Phenolphthaleïn (boiled) .	7·15	·278

(*To be continued.*)

THE PUBLIC PRESS ON THE SALE OF POISONS.

From the OLDHAM CHRONICLE, *February* 23.

"Much attention has been drawn lately to the unfortunate facility with which poisons can be obtained by persons with suicidal tendencies, or for such purposes as the poisoning cases at Liverpool, and it is to be hoped the subject will not be dropped before something is done to remedy the grievance. It is a crying evil, and we are not surprised at newspapers all over the kingdom calling for some alteration of the present state of things, which is disgraceful to a civilized community. The Pharmacy Act, of 1868, was intended to abolish this practice; but, unfortunately, it has proved inadequate. By that Act it was made compulsory on chemists, under heavy penalties, to label certain scheduled articles with the vendor's name and address, the name of the substance, and the word "poison." In this class were included laudanum, paregoric, and all preparations of opium, oxalic acid, and many other deadly drugs; while in respect to vermin killer, prussic acid, and others, the sale was also to be registered, and the articles only to be sold to persons known to the vendors, or introduced by a witness known to the seller. The same law also enacted, for the safety of the public, that after December 31, 1868, it should be unlawful for any person to sell or keep open shop for the purpose of retailing, dispensing or compounding poisons who was not a registered chemist, and that no person should assume the title of chemist, or any such similar name, under the penalty of £5; and it was also enacted that no person should be enrolled as a chemist unless he showed his fitness for the work by passing certain severe examinations approved of by the Privy Council. There is nothing in it to prevent an unregistered man keeping a chemist's shop, provided he does not call himself a chemist, druggist or pharmacist. He can call his shop a "drug shop," or himself an "herbalist" or "drysalter," and not offend, so long as he does not sell poisons enumerated in the Act. But this he is bound to do after a time from the fact that they are things in daily demand, and when his customers ask for syrup of squills or some other simple cough remedy they are annoyed at not being supplied with paregoric or syrup of poppies to go with it, and so he has to break the law to retain his business. Hence the great danger to the public. People who knowingly break the law for the purpose of gain have easy consciences, and to this source many mysterious deaths might be traced, but for one fact, viz., that these illegal traders seldom label the goods they sell, and so the chance of being detected is lessened. Another great evil is the habit, that is daily gaining ground, of small grocers and hucksters selling "Godfrey's Cordial," cough mixtures, and other articles containing opium, in violation of the Act. The extent to which these things are done is shown by the evidence given at an inquest, at St. Helen's, a few days ago. Superintendent Johnson, in answer to the coroner, stated that in St. Helen's alone there were ninety-three such shopkeepers, who sold preparations containing opium and other powerful drugs, such as the preparation that had caused the death of the child upon whose body the inquest was held. The jury, very properly, desired to make a presentment that these people should be absolutely prohibited from selling these things, and that the law should be put in force against them. But then arises the question—whose business is it to carry out the law, and why is it not done? The answer is, "Everybody's business is nobody's business." It is in the power of the Registrar of the Pharmaceutical Society only to recover penalties for falsely using the title of "chemist," but it is free for anyone to prosecute and recover penalties from all persons who sell poison otherwise than in accordance with the Act. It is a matter for the police to take up, and, perhaps, this would have been done long ago but for a want of knowledge of the provisions of the Act."

MENTHOL CONES AND THE MEDICINE STAMP ACT.

We have been favoured by Messrs. T. Christy and Co. with copies of the following correspondence:—

"The Commissioners, "*February* 15, 1884.
"Inland Revenue,
"Solicitor's Department, No. 84,
"Somerset House.

"Sirs,—Referring to our two interviews with you on the subject of menthol cones, we understand—

"1. That if pure menthol (*Mentha arvensis, f. piperascens*) is used, under these circumstances we may use labels and forms of advertisement advocating these cones as a remedy and relief in cases of nerve pain, neuralgia, headache, etc.

"2. Should wax or any other substance be added to the menthol, then it will be liable to the usual patent medicine stamp.

"3. Should advertisements in the papers, handbills or circulars of any firm recommend any 'mixture of menthol,' it is liable to the Act, and must be sold under a stamp.

"4. It has been suggested that as the wax prevents the menthol in the cone causing too much irritation of the skin, and again as the wax facilitates the plan of fixing the cone in a holder which is part of the box, that if a declaration were made on the label,—

Menthol . 90 per cent.
Wax . . 10 per cent., or

'Menthol cone with 10 per cent. of wax,' this would place it outside the claim for a stamp?

"We beg your reply to this letter making any point more clear that you may consider obscure, and we will make this decision known to the trade.

"We are,
"Your obedient servants,
(Signed) "THOMAS CHRISTY AND CO."

"R 1363, Stamps 18784.

"Inland Revenue,
"Somerset House, W.C.,
"*February* 21, 1884.

"Gentlemen,—The Board of Inland Revenue have had before them your letters of the 13th, 15th and 16th inst. to their solicitor in regard to the penalties incurred by your having sold unstamped 'Menthol Cones,' a preparation composed of menthol and wax, advertised for the relief of headache, toothache and neuralgia; and I am to acquaint you that upon the understanding that you will in future conform strictly to the provisions of the law, they have ordered that no further proceedings be taken in the matter.

"In reply to the inquiries contained in your letter, I am directed to state—

"1. That if pure menthol only be used, without any mixture with any other ingredient whatsoever, labels and advertisements recommending it as a remedy may be used without any liability to stamp duty being incurred.

"2. That should wax or other substance be added to the menthol it will, as recommended, be liable to stamp duty.

"3. That advertisements, handbills or circulars recommending any 'mixture of menthol,' would render the preparation chargeable.

"4. That a declaration on the label that the preparation consisted of—

Menthol . 90 per cent.
Wax . . 10 per cent.

would not avoid liability.

"I enclose for your information extracts from the Acts of Parliament regulating and imposing the stamp duty on medicines.

"I am, Gentlemen,
"Your obedient servant,
(Signed) "W. H. COUSINS."

The Pharmaceutical Journal.

SATURDAY, MARCH 1, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ANTISEPTIC DRESSINGS.

ONE very perceptible result of the recent enormous development of the antiseptic mode of treatment in surgical cases, which is now commonly designated under the term "Listerism," is that the surgeon has attained to a wider perception of the services that the pharmacist is able to render to him as well as to other practitioners of the healing art. On the other hand, the pharmacist has watched with an interest at least as keen as that of other members of the community the gigantic strides that have been made during the last few years in the treatment of wounds, and has found himself able sometimes—in a humble degree, it may be—to contribute to the progress by the utilization of his technical knowledge in the manipulation of antiseptics. This greater approximation of the surgeon and pharmacist was well illustrated at a recent meeting of the Military Medical Society, at Woolwich, in a most interesting discussion that followed the reading of a paper by Surgeon-Major C. H. GODWIN, on "Antiseptic Surgery in its Application to Field-practice." It is not intended to trespass here upon the domain of surgery by referring in detail to the special subject of the paper; our purpose is rather to mention some statements that were accessory and accidental to the discussion and that seem to us to present points of interest to the pharmacist. But as the value of these points is necessarily dependent upon the importance of the principal topic, we may go so far as to say that from the statistics quoted and the general consensus of opinion in the discussion it is apparent that recovery from a wound—whether inflicted in a battle or by the knife of a surgeon—is largely dependent upon the immediate occlusion, when possible, of the wound by means of suitable antiseptic dressings. Professor REYHER, indeed, has divided his cases into the "*befingerte*" and the "*unbefingerte*," — *i.e.*, cases that had been fingered by somebody before himself and cases which had not,—and one quotation of statistics will serve to show what this difference may mean. In the Russo-Turkish war Professor REYHER happened to have fourteen cases of gunshot wound of the knee-joint, seven of which were "fingered" cases and seven were "unfingered." At the time of writing to Sir JOSEPH LISTER six out of the seven "fingered" cases had succumbed and the seventh was in high fever, whilst all seven "unfingered" cases were alive and only one had suffered from fever, which was attributed to a severe face wound that could not be treated antiseptically.

Of course, therefore, antiseptic dressings naturally formed an element of considerable importance in such a discussion, and it is to mention some of the experience in respect to these, as related by different speakers, that is the special object of our referring to the subject in these columns. The author of the paper does not manifest a very marked preference for any particular dressing, provided that it be light, dry, antiseptic and absorbent, as, for instance, salicylated lint or cotton, boracic lint or cotton, or absorbent cotton; though he thinks a prepared cotton wool has the advantage that even if all the antiseptic has disappeared it would still act as a mechanical filter. Dr. W. F. STEPHENSON referred to the differences between non-volatile antiseptics, of which salicylic acid, and to a lesser degree boracic acid, might be taken as a type, and volatile antiseptics. He pointed out that whilst eucalyptus oil is valuable on account of its non-irritant properties, it is highly volatile and under certain climatic and other conditions might volatilize and leave the dressing in this respect useless. He, however, finds eucalyptus oil useful in the preparation of an antiseptic "cream," which is enclosed in an ordinary collapsing tube such as is used for scent fountains and is thus available in a portable form for anointing fingers or instruments before an operation, or even for pouring into a wound. He also described a dressing made by saturating spongio piline with a definite proportion of salicylic acid and then covering it with a film of wax impregnated with a volatile antiseptic, such as eucalyptol or carbolic acid, by which means he considers an antiseptic absorbent is provided so as to receive any discharge, together with the material for maintaining an antiseptic atmosphere in contact with the surface of the wound. Sir WILLIAM MACCORMAC, whose wide experience in military surgery allows him to speak authoritatively, said that of all known antiseptic substances iodoform seemed for the first dressing of the wounded by far the best, as it possesses the valuable properties of being very little poisonous unless applied in undue quantity, non-irritant to a wounded surface, insoluble in the discharge from a wound, and volatile and antiseptic to a remarkable degree. Deputy-Surgeon-General MARSTON also referred to the use in Egypt of iodoform as an application to wounds or, mixed with other substances, to the eyelids in purulent ophthalmia, and said that since seeing the results there he had had some miniature dredges made for using the remedy. It appears that in an advanced depot for the wounded on the day of the battle of Tel-el-Kebir, the treatment adopted was first to wash the wound and surrounding part with a solution of carbolic acid (1 in 20) and then to dust the wound lightly over with iodoform; next a piece of protective was dipped in the carbolic solution and laid upon the wound, upon which were placed two or three layers of boracic lint and above that the gauze bandage. The cases so treated did very well: when visited at a subsequent date there was no smell; the hospital atmosphere was perfectly pure and the wounds showed little or no discharge. As a material Professor LONGMORE spoke very highly of "wood wool," in respect to its absorptive powers, which he said exceeded those of cotton-wool, tow, or any substance of the kind. But although extremely soft, elastic and absorbent it has the disadvantage of not exercising any antiseptic action upon the discharge taken up by it; consequently although half a grain per cent. of corrosive sublimate is found sufficient to keep the "wood wool" itself aseptic and preserve it from putrefactive change that quantity does not seem sufficient to rely on for the protection of the wound also.

It may be almost assumed that the interest of the meeting to the surgeons present culminated in the speech of Sir JOSEPH LISTER, nor are his remarks by any means devoid of interest to pharmacists. The antiseptic to which he referred chiefly was corrosive sublimate, of which substance he appears to entertain a very high opinion on account of its wonderful effectiveness, combined with its cheapness. Referring to its use with "wood wool," he objected to that substance on account of its bulkiness, and also, like Professor LONGMORE, because the conditions under which the antiseptic is present in it are not satisfactory. Sir JOSEPH LISTER is of opinion that linen rags form at least as effective a material after they have been steeped in a solution of corrosive sublimate and dried. At present he is engaged in making some experiments with a view of obtaining corrosive sublimate in a more convenient form for application, and as a step in this direction he proposes to utilize its great solubility in glycerine. Although this property is not usually mentioned in text-books, it is not a new observation, as the speaker appears to think, for at least a quarter of a century ago corrosive sublimate was included by PARRISH in a list of substances "readily soluble in glycerine," and the fact is mentioned also in STORER's 'Dictionary of Solubilities.' Sir JOSEPH LISTER has found that corrosive sublimate is soluble in one and a half times its weight of glycerine in the cold, and this concentrated solution he proposes to dilute with water as required to form a solution of 1 in 1000, or other desired strength. For the preparation of antiseptic rags he recommends to dilute the glycerine solution with two hundred parts of water and use this aqueous liquor for steeping them in. Sponges also may be preserved in an aseptic condition most advantageously by means of this agent; for although when purified with carbolic acid they remain in a satisfactory condition for a considerable time, eventually the carbolic acid will leave them, in virtue of its volatility, whereas after purification with a solution of corrosive sublimate, sponges will remain aseptic an indefinite time until required for use. In a similar manner, instead of keeping carbolized catgut in oil, the speaker recommended that it be preserved dry, like silk, and simply dipped in the solution of corrosive sublimate for a few minutes when required for use. As to iodoform, Sir JOSEPH LISTER thinks that in the present state of our knowledge it is the agent that promises best as a first dressing for wounds with respect to portability and effectiveness. He considers it to be a very excellent antiseptic, although not the most powerful one; for it does not seem to destroy the poison of erysipelas so easily as carbolic acid, and it has been proved by experiment to be inferior to several antiseptics in destroying various bacteria. Nevertheless, in the form of iodoform wool it constitutes a very effective dressing, whilst in consequence of the non-irritating properties of iodoform and its insolubility in the discharges, he is disposed to think that to dust a wound over with iodoform powder and then cover it over with an absorbent substance, constitutes the best known treatment. For a similar purpose, Dr. LESSER, of Leipsic, has recommended that every soldier should carry in his knapsack a cartridge case full of an antiseptic powder consisting of two parts of boracic acid and one part of iodoform; but Sir JOSEPH LISTER would prefer the use of unmixed iodoform powder, on the ground that boracic acid is by no means so powerful an antiseptic as an equal bulk of iodoform.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next the 5th inst., when a communication will be read on "Logwood as a Test for Metals," by Mr. Arthur Weddell, and a paper on "The Chemical Composition and Properties of a Crystalline Principle obtained from Jambosa Root," by Mr. A. W. Gerrard. The chair will be taken at 8.30.

* * *

On another page will be found a portion of a correspondence that has taken place between the Board of Trade and Messrs. T. Christy and Co., with reference to the sale of "menthol cones." It will be seen that the Board has decided that if pure menthol only be used, without an admixture of any other substance, "labels and advertisements recommending it as a remedy may be used without any liability to stamp duty being incurred;" but that should wax or other substance be added to the menthol it will, if so recommended, be liable to stamp duty. No reason is given by the Board for this decision, but in publishing it we think it right to recommend that in the absence of such an explanation the greatest circumspection should be exercised in applying the ruling to what might appear to be analogous cases. At the end of the Schedule to the Patent Medicines Act (42 Geo. III., cap. 60), there are some "special exemptions" mentioned, among which are "all medicinal drugs whatsoever which shall be uttered or vended *entire* without any mixture or composition with any other drug," etc. It may be, therefore, that "menthol" is considered to be an "entire" drug; but we should like to know the opinion of the Board as to the definition of the essential oil of which it originally formed a portion before risking the application of the ruling to such an article.

* * *

A *projet de loi* has been introduced into the French Legislature for the reorganization of the inspection of pharmacies in France. It proposes that pharmacies and the stores of druggists and grocers shall be inspected at least once every year by special inspectors appointed by the Minister of Commerce. These inspectors, of whom there would be about ninety, or one for each department, would also be charged with the supervision and inspection of depots of mineral waters and manufactories of artificial mineral waters. In the pharmacy they would have the power to examine drugs and pharmaceutical preparations, as well as dietetic articles, and to confiscate any that might be found adulterated or to have undergone alteration, and also to deal with breaches of the law as to the sale of poisons or hydrocarbons. The fee payable for the inspection of a pharmacy would remain, as at present, six francs, and four francs for a drug store or grocery. The Bill has aroused the opposition of influential pharmacists, and it appears to be looked upon in some quarters as a covert blow at the Bill of M. Naquet, of which a summary was given in this Journal some months since.

* * *

Some further details have been published respecting the Paris Municipal Laboratory (see before, p. 345), from which we learn that the staff of the establishment consists of a director at a salary of £240, a deputy at £180, one first class chemist at £96, three second class chemists at £64 each and three attendants at £60 each. The "out-door," staff consists of eight first class inspectors who are paid £96 yearly each, eight second class at £72 each, and thirty-two ordinary inspectors. It would appear therefore that in Paris the services of an unskilled inspector are appraised at a higher money value than those of a skilled chemist. The number of the analyses made in the year was 6517, of which 3958 were gratuitous, 378 were paid for, and 2181 were ordered by the inspectors. The results reported were that 1565 samples were good, 1523 passable, 2608 bad, and 562 dangerous.

* * *

In a review of Proctor's 'Practical Pharmacy,' in the current number of the *Dublin Journal of Medical Science*, the writer makes some pertinent remarks upon the probable results of the tendency in the present day of some medical men, either through "ignorance or laziness," to ignore legitimate prescribing altogether. He says—

"Indeed it is by no means an unusual practice among some medical men, when called upon to prescribe, to do so not from any study or knowledge of their own of drugs or of disease, but with the aid of the last list of formulæ of 'selected remedies,' or of 'pills' or 'granules,' with perhaps an accompanying 'Index of Diseases,' that may have been sent to them by the active agent of some enterprising drug firm. Such a system of routine book-prescribing, although it may have some conveniences, is, we think, derogatory, and as likely to become injurious to the profession of medicine as to that of legitimate pharmacy, and certainly cannot add to the credit of either. If the public, as they surely will, find that they are being habitually dosed by book formulæ, they will probably, by procuring these lists for themselves, take their dosing into their own hands; and it is not impossible that, in some cases, by running his eye down the list, a patient might select as good a 'combination' for himself as would have been made by a practitioner who adopts such a system of prescribing."

* * *

In Victoria, towards the end of the year, fifty convictions were obtained in three weeks under the provisions of the Act for regulating the Sale and Use of Poisons, by which the sale of scheduled poisons is restricted to medical practitioners, registered pharmacists, and (in outlying districts) certificated dealers. A considerable proportion of the convictions were for the sale of chlorodyne, although that compound is not mentioned by name in the schedule to the Act.

* * *

It is announced that for the encouragement of original research in sanitary science three Scholarships, each of the value of £250, tenable for one year, are offered for competition by the Grocers' Company. Two of these scholarships will be filled up in May next, and candidates, who must be British subjects, must send in their applications not later than the last day of April.

* * *

On Tuesday the Lord Chancellor informed the House of Lords that in respect to the Institute of Chemistry Bill the examiners had reported that the standing orders had been complied with. The Bill, which has not yet been issued, now awaits a second reading.

* * *

In addition to the gentlemen whose names were mentioned last week we understand that Mr. Thomas Greenish, of London, has been elected an Honorary Member of the Philadelphia College of Pharmacy, and Dr. Symes, of Liverpool, Mr. Richard Reynolds, of Leeds, and Mr. A. W. Gerrard, of London, have been elected Corresponding Members.

* * *

At the next meeting of the Chemical Society, to be held on Thursday, the 6th inst., the following papers will be read.—"On the Hydrolysis of Sulpho-compounds and on the Recovery of Benzenes from their Sulphonic Acids," by Dr. Armstrong and Dr. Miller; a "Note on the Behaviour of the Nitrogen of Coal during Destructive Distillation and a Comparison of the amount of Nitrogen left in Cokes of various Origin," by Mr. Watson Smith; and a "Note on some Experiments to Determine the value of Ensilage as a Milk and Butter-producing Food," by Mr. T. Farrington.

* * *

A meeting of the London Section of the Society of Chemical Industry will be held in the rooms of the Chemical Society, Burlington House, on Monday next, March 3, when papers will be read on—(1) "The Manufacture of Cuprammonium and Zincammonium and their Technical Applications;" (2) "The Filtration of Potable Waters;" (3) "Some Applications of Kieselguhr."

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

February 19, 20, 21 *and* 22, 1884.

Present on each day—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow was present on the 21st on behalf of the Privy Council.

MAJOR EXAMINATION.

19*th*.—*Seven* candidates were examined. *Three* failed. The undermentioned *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Haddock, James ....Bedford Leigh.
Randall, William Joseph..... ...Wareham.
Roberts, Edmund..................Upper Norwood.
Wiggin, John Chinery............Ipswich.

MINOR EXAMINATION.

19*th*.—*Twenty-four* candidates were examined. *Fourteen* failed. The undermentioned *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Alderton, James ....Leamington.
Arthur, Samuel.....................Redruth.
Barnett, William Zachariah ...London.
Bates, John ....Bicester.
Botham, William Bland ....Sheffield.
Broumpton, Frederick Richd...London.
Clarke, Richard ....Ruthin.
Cockerill, Thomas ....Lynn.
Collen, William Cresswell ......London.
Davis, Frederick ....Oundle.

20*th*.—*Twenty-nine* candidates were examined. *Twenty-four* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Baker, Sidney George ....High Barnet.
Duckworth, William ....Blackburn.
Farlow, James Southward ......London.
Fellows, Vincent Litchfield ...London.
John, Benjamin ....Narberth.

21*st*.—*Thirty* candidates were examined. *Eighteen* failed. The undermentioned *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Baker, Walter James ....Dorking.
Jackson, Frederick ....Manchester.
Kirby, Herbert Edward.........London.
Leach, John Pickering ....New Shoreham.
Mack, George Henry ....Holt.
Miller, William Henry ....Howden.
Peacock, James, jun. ....Sunderland.
Potter, John Henry...............Nottingham.
Ramsey, William..................Pocklington.
Richards, Thomas Coombs ....London.
Sapsed, William George.........London.
Shallcross, Joseph Richard......Tunstall.

22*nd*.—*Twenty-seven* candidates were examined. *Seventeen* failed. The undermentioned *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Crowder, Charles Joseph H. ...London.
Jackson, George Granger ......Buxton.
Johnson, Frederick Edward ...Hull.
Sinclair, Matilda Anne ... .Llandudno.
Smith, Samuel Henry............Leamington.
Southwell, Charles Bullock......Bridgnorth.
Spratling, Walter...................Boston.
Tupholme, Frank..................London.
Wells, Arthur John...............Leamington.
Wookey, Edgar ....Bristol.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificate of the College of Preceptors.

Strutt, George Henry ....Saltley.

Certificate of the University of London.

Green, Henry Selby ....Penzance.

NORTH BRITISH BRANCH.

EVENING MEETING.

The fourth meeting of the present session was held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday evening, February 20, at half-past eight o'clock. Mr. John Nesbit, President of the Branch, in the chair.

The minutes of the former meeting were read and confirmed.

DEATH OF EMERITUS-PROFESSOR BALFOUR.

Before proceeding to the business of the evening the President of the Branch said that those present were aware that in the death of Emeritus-Professor Balfour the Society had lost one of its distinguished honorary members. The late professor had in various ways assisted and promoted the work of the Society, and had always shown a kindly interest in the Branch. Most Scotch pharmacists were familiar with Professor Balfour's published writings, and they would join with him in regretting the loss which natural science had received by his death, and in sympathizing with the bereaved family of the professor.

The Secretary to the Branch then intimated the following donations:—

To the Library—

'Year-Book of Pharmacy and Transactions of the Pharmaceutical Conference, 1883.'
From the COMMITTEE OF PUBLICATION.

To the Museum—

Seven specimens of Potassæ Sulphas c. Sulphure.
From Mr. THOMAS MABEN.

Specimen of the fruit of Alexandrian Senna.
From Messrs. CLARK and PINKERTON.

Thanks were accorded to the donors.

A note was then read on—

TARTALINE, A CREAM OF TARTAR SUBSTITUTE.

BY PETER MACEWAN.

My attention has lately been called to a substance which, under the name *Tartaline*, is being sold by grocers as a substitute for cream of tartar, and which from its low price seems to have commanded a ready sale amongst retailers.

The substance comes into the market as a white powder of a strongly acid taste, but devoid of that grittiness which characterizes cream of tartar. When treated with water it behaves similarly to the acid tartrate, adhering to the edge of the vessel and dissolving but slowly in the cold, so that a superficial examination of the substance is apt to convey the idea that it is in some way related to cream of tartar. A more extended examination shows, however, that it is not so. Thus we find that it is completely soluble in a small volume of hot water, the solution formed being intensely acid. A drachm of the substance dissolves in two ounces of cold water in the course of an hour, and this solution by the ordinary tests gives reactions for potash and a trace of iron in combination with sulphuric acid. The powerful acidity of the aqueous solution appeared to indicate that the substance is acid sulphate of potash, and following this indication I found that 0·51 gram of the salt yielded 0·87 gram of barium sulphate = 0·506 gram $KHSO_4$. Another weighed portion lost nothing on exposure in the hot air chamber for an hour. The substance, it thus appears, is simply the acid sulphate of potash, a salt which, though at one time recognized by the Dublin and Edinburgh Pharmacopœias, is now obsolete as a therapeutic agent. Its introduction by grocers as a substitute for cream of tartar is not calculated to render much benefit to the public, for since it possesses weight for weight, fully 50 per cent. more acidifying power than cream of tartar, its use for baking purposes is not likely to give pleasant results. If the substitution stopped here we might safely leave the public to judge of its suitability for domestic purposes, but there is a probability that ignorant retailers may assume that it possesses medicinal properties similar to cream of tartar, and have no hesitation accordingly in supplying it for medicinal purposes. Viewed in this light, the indiscriminate sale of tartaline assumes a dangerous aspect, while to the pharmacist it illustrates a development of a phase of that competition which he has to contend with at the present time.

A vote of thanks was moved by the President, and after a few remarks on the subject, the next paper, on "The Composition of Potassæ Sulphas c. Sulphure," by Messrs. Maben and Dechan, was read by the Secretary to the Branch. The paper will be found printed on p. 967.

The President of the Branch, in moving a vote of thanks to the authors, said that he had observed the difference in the article as prepared at different temperatures, and had noted that the amount of sulphuretted hydrogen liberated by acids varied with different samples. The authors in directing attention to the cause of this variation had rendered good service, for though the compound had only a limited application, it was but right that it should be uniform in composition.

The motion having been heartily responded to, the President called upon Mr. Patrick Geddes to deliver a lecture on—

The Morphology and Physiology of the Cell.

BY PATRICK GEDDES, F.R.S.E.,

Demonstrator of Botany, Edinburgh University.

Twelve months ago, I was invited to lay before you a statement of the position of my studies of the cell, and at that time I pointed out the importance of the cell theory, and outlined the history and the existing state of the subject. The conception of the organism as composed of unit masses of protoplasm, or cells, is really the deepest generalization in morphology. The cell, however, is usually conceived of as essentially comparable to the common amœba, a gelatinous mass of protoplasm of irregular, constantly changing form. I pointed out, however, that this conception was not sufficient to explain all, or even any fair proportion, of the problems which the study of physiology, vegetable and animal, brings before us. For instance, it does not enable us to form any distinct opinion as to whether plants and animals are really distinguishable, or whether, with Haeckel, we must constitute an intermediate group—the Protista—for the lowest vegetable and animal forms. If we are Darwinians at all we must be thorough-going ones. We need not shrink from pushing the theory to its uttermost limits, and considering whether plants or animals are descended from one or two distinct stocks. Then again, on the same theory we are bound to endeavour to account for the variation, or tendency to variation, in organisms which has given rise to such enormous multitudes of plants and animals. I attempted to show that the difficulties were cleared up by substituting for the conception of the cell as a simple amœboid organism the notion of a "cell-cycle,"*—of a cycle of forms through which the cell is observed to pass in certain of the lowes organisms, hitherto generally regarded as aberrant fungi, the *Myxomycetes*. These most commonly occur as vast irregular masses of protoplasm (like the *Æthalium septicum* of tanyards) flowing here and there and in all sorts of grotesque forms. This irregular slimy mass, or *plasmodium*, is compounded from the union of many amœbæ; after a season of movement in that state, it draws itself together into some definite form, generally into a more or less spiroidal mass, which surrounds itself by a cellulose wall, and thus encrusted, lies for a time perfectly quiescent. After a season, however, the protoplasm breaks up into a number of small, but definite, more or less rounded masses, and these ultimately break loose through an aperture in the wall, and swim out as active ciliated organisms. The little masses of protoplasm swim along by a delicate vibratile thread of protoplasm, by which they propel themselves. This thread acts like a tiny oar and enables the organism to find its way through the water. So that here we have a cycle of four distinct phases, the amœboid being one, and only one, of the four. The four phases are called, the encysted, the ciliated, the amœboid and the plasmodium. Now this restatement of the cell theory proposes to refer the constituent masses of plants and animals not to the amœboid alone, but to some one or all of these four phases through which the cells of the lower organisms tend to cycle.

If time allowed I might show that the various groups of lower plants and animals are all distinctly referable to this one series of forms. For instance, simple microscopic plants, like *Protococcus*, which of course are provided with cellulose walls, are very often in the habit of leaving their wall and issuing in the ciliated state, and then settling down again. In the same way a great many of the microscopic animals exhibit more or less of these phases. For instance, the monads which one finds in putrefying infusions are typically ciliated, but their life-history has recently been investigated, and it has been shown that these creatures fall down into an irregular amœboid state, and subsequently encyst themselves. So that, if time allowed, I might justify the proposition that the lower plants and the lower animals are referable to this simple primitive type of the *Myxomycetes*. This diagram expresses the matter in a clearer way. There is a myxomycete; here encysted, here ciliated, here amœboid, and here plasmodium. A bacterium, of which one hears so much, exhibits an alternation between the encysted and the ciliated state. Then again, an ovum or egg-cell corresponds at first to the amœboid state, and later to the encysted. So in this way one gets a conception of plants and animals being much more closely related in cellular structure than is commonly assumed. One regards, in fact, the lower plants and animals, and of course the higher plants and animals also, as being specialized from a form of which this cycle affords us a tolerably distinct idea. I might go on to show that the cells in the higher animals exhibit the same cycle; that, for instance, a blood corpuscle of a sea-urchin, or probably also the diseased cells of higher animals, run through a cycle of the same kind

That, then, is a very rudimentary outline of the theory which underlies the present paper. I propose going on to discuss the problem of the cell structure. What is the internal structure of the cell, and what is the explanation of that very remarkable phenomenon of contractility which protoplasm constantly exhibits? Great attention has lately been paid to this question, but there are still some problems to settle; let us consider some of these. The lowest amœboid forms are simply granular masses of protoplasm of quite irregular shape, and tolerately homogeneous. If you look at higher amœbæ on the other hand, you find that they exhibit a granular interior, and a clear pellucid exterior in which no granules are visible. Again, organisms like the Foraminifera are provided with thread-like, granular and reticulated processes from their protoplasm. On the other hand in forms like the Radio-

* Geddes, 'Proc. Roy. Soc. Edin.,' 1883-4, "A Restatement of the Cell Theory."

laria the processes instead of being granular are perfectly clear and transparent, instead of uniting with each other they remain perfectly distinct, instead of moving and flowing they remain perfectly quiescent. How is that to be explained? As yet no theory affords any ground of explanation.

Again, there are remarkable changes visible in eggs of all kinds of animals before fertilization and during it, and similar remarkable phenomena when cell division is going on. Are these granules I am speaking of really separate grains of denser matter, or the expression of the intersections of a net-work of denser protoplasm? Questions of this kind are at present being hotly debated among histologists. Then again, one of the most difficult problems, one indeed which has been discussed during the last thirty or forty years, is the problem of muscular contraction. No two histologists are agreed about it; an enormous mass of literature has been accumulated, and as yet with comparatively little result, and comparatively little unity of opinion. One cannot always be sure whether the muscle fibres of the lower animals are striped or unstriped. Then again, another series of problems which the investigator must face is that which was raised by Mr. Darwin.* Mr. Darwin put the living cells of the tentacle of the sun-dew under the microscope, and watched what was going on within their delicate cellulose walls. He showed that within this cell, when it was digesting, or when he treated it with some reagent like my dilute solution of carbonate of ammonia, or when he applied heat or electricity, the protoplasm broke up, separated into two distinct substances, one of them remaining very much the same as before, the other forming all sorts of irregular drops, granules and threads, constantly changing and flowing together.

Now, I have gone over a number of difficult questions, the structure of amœba, the question why foraminifera possessed delicate filaments of protoplasm which are granular and moving, while the radiolarians possessed stiff and non-granular threads; the question of the structure of muscle and the question of aggregation. The hypothesis by which I propose to explain and unite all these phenomena is that of extending the conception of aggregation from the vegetable cell to the cell generally. Why should not the granules be simply the expression of the same change which is going on in the insectivorous plant? Why should not protoplasm, in fact, be separating itself into the same two substances which we have there? In the same way the processes of the foraminifera, which are granular, are so because they are aggregating. In the granular interior of the amœba this process is going on; in the clear exterior not so, and therefore the protoplasm remains clear and simple. Let us see what more this conception will do for us. In the first place it suggests,—setting out from these researches of Mr. Darwin—an investigation as to what changes chemical substances produce upon cells. That of course is something which touches upon the general questions of therapeutics and pharmacy in the most direct way.

The question of applying chemical reagents to living cells is, of course, the essence of the whole affair. Now carbonate of ammonia is not all the Pharmacopœia, but it is a substance which yields most striking results when applied to the living cell. For instance, if you apply it to the sun animalcule you will notice the most curious change. The creature actually tumbles down and dies in a few minutes, losing its complex protoplasmic structure, and collapsing into a simple amœba before it breaks up. Well, what is to prevent anyone from applying a whole series of reagents, carbonate of ammonia, alkaloids, different salts and so on, to various organisms; not only to protozoa, but to the simpler plants; not only to the lower organisms, but also to the cells of higher organisms? I have no doubt, for instance, that such reagents would produce a noticeable effect upon the epidermic cells of tadpoles. One could so begin to get some approximation of the therapeutic effects of reagents upon the cells of invertebrates themselves, an investigation which might carry us far. And, again, if time allowed, I might go on to show how this explanation fitted and met various problems, such as those which I have sketched out. Take that of muscular structure alone. If we magnify muscular fibre enormously we see that the fibrils are made up of strongly refracting portions, alternating with clearer spaces, in which dots or granules occur. Some observers say that they do not find these granules. Very good: they observed it when it was in a certain state of contraction.* Others find that the ends have come together and united: they observed it in a state of more complete contraction, and so on. Now that is thoroughly in unison with the conception of aggregation in the vegetable cell; we have a cell which separates into two kinds of protoplasm and nothing more. The union and change of rods and granules are simply the union and change which we observe in the insectivorous plant. This is rendered regular by the definite limit of the fibrils. I might develop this hypothesis, a hypothesis which, on the whole, explains the facts, but which does not as yet of course lay claim to any authoritative verification. I should be very sorry if you understood me to assert that this was demonstrated fact. I offer it simply as a hypothesis. Notice, however, one of the explanations which it affords us. Long ago it was pointed out, by Mr. Herbert Spencer for instance, that we have as yet no clue to the mode in which molecular movement is converted into the movement of masses. By what change is it that the whole fore-arm can be elevated in this way by the use of the biceps muscle? How is it that the multitude of little molecular movements are added up to the large movement of the mass? No explanation is forthcoming on any view but this. If these masses of protoplasms are elongated, they tried to shorten and broaden and draw themselves into a sphere. If all these multitudinous elements of the muscle are drawing themselves towards the spherical form, are shortening and broadening, then of course you have an explanation of that general shortening and broadening which takes place in the contraction of the muscle. In the same way, if we have a drop of oil suspended in the water and it draws together into a sphere, it overcomes a slight resistance, it pushes aside the particles of water which surround it. The same thing will account then for the overcoming of resistance of masses; a muscle is able to lift a weight, because the sum of thousands of millions, perhaps, of elements all contracting and pulling together make up a power which overcomes this large resistance. And so molecular movement is converted into movement of masses; the overcoming of minute resistance is converted into the overcoming of a large mass resistance.

Now, one question more. Why should there be two protoplasms? How is it that if you treat protoplasm with a reagent it breaks itself up into two substances? I do not see how it is possible to explain that; it is an observed fact. I would be glad if any member of the Society would enlighten me on this point; could indicate any parallel case in inorganic or organic substances, where a chemical change separates a substance at first homogeneous into two distinct substances which afterwards reunite into its components, or in which an electric current temporarily segregates a complex mixture. I am not aware that any parallel case exists, but we know that it would be very inportant if something analogous could be found. This is therefore suggested as a problem, without any solution being offered. But let me just point out one interesting corollary from the general notion of cellular therapeutics. Let me start again with an observed

* 'Insectivorous Plants.' London: 1875. Article, "Insect. Plts.," 'Encyclop. Brit.'

* See Professor Rutherford's recent paper. 'Trans. Roy. Soc. Edin.,' 1883.

fact. When amœboid cells unite into a vast compound amœba, there is visible an extraordinary intensification of the activity of the mass, that is to say, when the little amœbæ, a hundred or two of them together, are united into a single compound mass they throw out extraordinarily long processes; they career about under the field of the microscope, sending out filaments of protoplasm enormously longer than any amœba can do. What one amœba cannot do, the union of many amœbæ does in a most striking manner. Why is this? Why should the union of many amœbæ produce such activity? It seems to me that these numerous amœbæ, when they flow together, serve as it were as food to one another, the protoplasm of one is poured into that of others, the waste products, the surplus water and so on, are squeezed out, and in this way we get a vast composite amœba of which the activities are summed up from its components. But more than that we saw how carbonate of ammonia was powerfully stimulating to protoplasm, and Mr. Darwin's researches have shown that alkaloids and waste products are excessively stimulating, and set up the most extraordinary aggregation, so that a poison, for instance, sets up too much of this movement of aggregation in the protoplasm. There, then, is actually a use, not only for the protoplasm, but also for the waste products, the waste product of one cell acts as a stimulant when it unites with the protoplasm of another. So, for instance, one may speculate that the store of alkaloid in a coffee bean is used to stimulate the protoplasm of the germinating plant. We may apply this notion of conjunction of cells to the union of the ovum and spermatazoon in fertilization; we may imagine, and we are reasonably entitled to do so, that the spermatazoon brings not simply an additional mass of protoplasm, but brings something of distinctly different chemical properties, differing perhaps by possessing substances especially stimulating to the vast mass of protoplasm of the ovum.

So far, of course, these considerations are speculative, but before a Society of this kind I think it not illegitimate to call attention to these speculations in cellular chemistry and cellular therapeutics.

The lecturer frequently referred to large coloured diagrams in illustration of different statements, and also rendered the discourse of greater interest by means of extempore drawings.

Mr. H. Bellyse Baildon, in proposing a vote of thanks, said that he had attended a great many evening meetings, but he did not think that he had ever listened with more rapt attention than he did to Mr. Geddes's interesting lecture. He thought that it had a special value in so far as it not only gave the issue of a number of most interesting results of his own, but it pointed out to others a most valuable field for research. The suggestions regarding the effect of chemicals upon cellular tissue of various kinds was most valuable, and skilled microscopists would not fail to obtain good results in carrying out the suggestion. The manner in which the lecturer was received was a sufficient proof of the interest attached to the subject, and this, he felt, was due to Mr. Geddies's wide generalizations, which, while suggestive, gave great interest and stimulus on the study of the subject.

Mr. Napier seconded the motion, which was heartily responded to, and in the course of reply—

Mr. Geddes stated that he thought that skilled pharmacists might conduct some of the researches which he had indicated; they would not require continuous observation, but only frequent glances of attention during several hours. The interest of the admission of a drug did not at all stop when it was conveyed to the stomach, but really began then. The question was how did these drugs affect the cells of the organism? It was really possible to investigate this by means of the microscope, and by applying solutions of proper strength to microscopic organisms or to tissues of animals.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The annual meeting was held on Friday, February 22, at the Museum and Library, Queen's Road; Mr. G. F. Schacht, President, occupied the chair.

The report of the Council and the statement of accounts were received and adopted.

The following gentlemen were elected to serve as members of the Council for the ensuing year, namely—Messrs. Allen, Berry, Pitman, Schacht, Stroud, Warren, White and Wretts.

The Chairman congratulated the incoming Council upon the slight numerical increase upon the lists, both of the members and of the associates of the Society. He was also very glad to hear from his friend, Mr. Warren, who took such anxious care of the Library, that the books were so much read and studied. He hoped when the new Council had fully constituted itself, some good useful scheme for still further developing the benefits of the Association would be arrived at.

DOVER CHEMISTS' ASSOCIATION.

At the quarterly meeting of the Dover Chemists' Association, held on the 21st of February, the following paper was read—

Peroxide of Hydrogen,

its actual strength as found in commerce.

by j. f. brown.

The increasing use of this chemical and its wide variations in price, led me to conclude that a simple test of its quality might be found useful.

The method I propose, is to make its capacity for raising a ferrous salt to the ferric state the measure of its value, thus $2FeSO_4 + O + H_2SO_4 = Fe_2 3 SO_4 + H_2O$, showing that 112 parts of iron require 16 parts of oxygen to bring about the change of state.

Pure unoxidized sulphate of iron would answer the same purpose using 278 parts, and I duplicated some of my testings in this way—without finding any discrepancy, but perhaps the employment of bright polished iron wire is, on the whole, to be recommended in preference.

As a convenient quantity, 44·8 grains of the latter were dissolved by a gentle heat in 15 fl. drs. diluted sulphuric acid in a glass flask lightly stopped with a pledget of cotton to prevent undue access of air; the cooled solution was carefully diluted to 5 fl. oz., transferred to a stoppered bottle and used as quickly as possible.

Five fl. drs. indicating $\frac{8}{10}$ths of a grain of oxygen formed the unit employed, and into this quantity the sample of peroxide to be tested was dropped from a burette until, after brisk stirring, it ceased to strike a blue colour with a drop of freshly made solution of red prussiate of potash.

The quantity used was then noted and the results are thus tabulated:—

Sample A	101	grain measures employed.
„ B	92	„ „ „
„ C	121	„ „ „
„ D	1500	„ „ „
„ F	93	„ „ „
„ G	87	„ „ „
„ H	80	„ „ „
„ I	93	„ „ „
„ J	42	„ „ „
„ K	226	„ „ „

Temperature 58° Fahr. Barometer 30 inches. Since a cubic inch of oxygen weighs ·3422 grain as compared with 252·45 grains, the weight of a cubic inch of water, $\frac{8}{10}$ths of a grain will occupy nearly 590 grain measures, and the actual volume strengths will be obtained by dividing 590 by the number of grain measures used in each case, thus: —

A	contained	5·8 volumes.
B	„	6·4 „
C	„	4 8 „
D	„	·4 „
F	„	6·3 „
G	„	6·8 „
H	„	7·37 „
I	„	6·3 „
J	„	14· „
K	„	2·57 „

Samples A and B were supplied as 10 vols. in the ordinary course of business.

C was old stock and turbid, only just enough being drained out to test with.

D was taken from a freshly opened bottle, supplied by the same wholesale house as A, but was inconceivably weak.

F was obtained for the purpose of testing from the firm who claim priority in introducing this article.

G and H were sent as samples by a leading firm of wholesale druggists as 10 volumes and 20 volumes respectively.

So also were I and J, and the latter was the only sample approaching even remotely, the double strength.

K had, I think, been kept some time.

I would only add that this paper had been projected and worked out before the publication in the Journal of two recent communications on the same subject.

HAWICK PHARMACEUTICAL ASSOCIATION.

The usual monthly meeting was held on Tuesday, February 12, when there was a fair attendance, Mr. Maben, Hon. President, occupying the chair.

The subject under consideration was, "Whether Coated Pills ought to be supplied to the Public."

Mr. J. A. Hislop, in opening the discussion, said that it was perfectly inexcusable to coat pills in order to hide defects arising from bad manipulation, and that it was unnecessary to coat them to cover their nauseous taste, as uncoated pills, after a lapse of twenty-four hours, acquire a hardened exterior, which keeps the taste from being felt for a much longer period than is required to swallow them. He had no objection to coating where this was used to prevent the solution of the pill till it reached the intestines; but where all pills are coated this exception in most cases becomes the rule. Coating is sometimes employed to prevent oxidation or volatilization of active ingredients, but pills of this class should be made when required. Lastly, coating is not sanctioned by authority, therefore should not be used unless specially desired. Mr. Hislop then detailed the results of a series of experiments with uncoated and coated pills, from which it appeared that the latter invariably required much the longer time before complete disintegration took place.

In stating the other side of the question, Mr. J. Craig, jun., said that coated pills keep soft much longer than uncoated pills, because the coating prevents the moisture from evaporating. This is especially desirable in such pills as pil. assaf. co., which if once allowed to harden would pass through the stomach unaltered. It would be wrong to use insoluble varnishes for coating, but pills can be coated so as to be perfectly soluble. Pills containing essential oils or camphor must of necessity be coated to prevent them losing their virtue, and many other pills require coating, otherwise the active ingredient would be oxidized. Then it was desirable to make pills as agreeable to the eye and as tasteless as possible, so that the tendency to nausea in invalids and others who have a difficulty in swallowing pills may be averted, but without coating this could not be done.

In the discussion that followed all present took part, and various opinions were expressed. One member stated that he knew a case where a youth took no fewer than six coated colocynth pills within twelve hours without the slightest effect being produced. The feeling of the meeting was that in some cases coating was necessary, and where not essential it was no disadvantage provided a readily soluble and harmless coating could be obtained. The experience of several members was, however, that the coated pills of commerce were often very unsatisfactory.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, February 21, Dr. W. H. Perkin, President, in the chair.

The following certificates were read for the first time:—H. Cave, F. W. Fleming, E. E. Graves, A. E. Lewis, S. Smith.

During the evening a ballot was held and the following gentlemen were declared by the scrutators, Drs. Wright and Hodgkinson, duly elected Fellows:—L. Archbutt, J. H. Burlans, D. Bain, W. H. Barr, R. A. Bush, P. S. Chantrell, A. F. Damon, H. C. Draper, T. R. Duggan, V. Edwards, W. T. H. Elsley, G. W. Gibson, F. W. Harris, T. Hilditch, R. E. Moyle, P. Morton, W. J. Orsman, F. R. Power, A. E. Simpson, C. W. Sutton, H. G. Shaw, E. F. Smith, F. W. Tompson, A. Tarn, E. W. Voelecker.

It was announced that the following changes in the Vice-Presidents and Council were proposed:—Vice-Presidents, Drs. T. E. Thorpe and W. Weldon, nominated instead of Dr. Crum Brown and Professor Emerson Reynolds, who retire; Council, Drs. Carnelly and Messel, R. J. Friswell and M. Carteighe, nominated in place of Captain Abney, Dr. Mills, Professor McLeod and G. H. Makins. Dr. Hodgkinson, Dr. Thorne and F. W. Toms were appointed Auditors.

The following paper was then read by Dr. Gilbert—

On the Composition of the Ash of Wheat, Grain and Straw grown at Rothamsted in different seasons and by different manures. By Sir J. P. Lawes and Dr. J. H. Gilbert.—This paper gives an account, including duplicates, of two hundred and fifty-three analyses, most of which were made by R. Richter, of Berlin. The ashes were prepared at Rothamsted, being burnt in oblong platinum dishes by surface heat in order to prevent, as far as possible, any fusion. Every ash is of produce of known history of growth as to soil, season and manuring. The experiments are arranged in three series. The first illustrates the influence of fluctuation of season from year to year, under three known, but very different, conditions as to manuring, during sixteen consecutive seasons. The second shows the influence of four characteristic seasons, two favourable and two unfavourable, under nine different conditions as to manuring. The third demonstrates the influence of continuous exhaustion or supply of certain constituents as it represents the proportionally mixed produce for the ten years 1852–61 and the ten years 1862–71 from ten differently manured plots. In the first series the three plots were respectively (1) unmanured; (2) treated with 14 tons farmyard manure per acre; (3) treated with about 200 pounds of ammonium sulphate and 200 pounds of ammonium chloride per acre annually. The principal points of interest in the analyses are the relative quantities of potash and phosphoric acid. The chief conclusions are—that with normal maturation the grain is of nearly uniform composition whatever the manure, that the deviations from normal mineral composition are associated with deviations from normal development of the organic substance, and that the season has much more influence on the mineral composition of the grain than the manure. An obvious difference can nevertheless be detected in the average composition of the grain under the different conditions as to manuring. Thus the grain grown by ammonium salts alone shows exhaustion of potash, and especially of phosphoric acid. In the second series of analyses the following four seasons were selected: 1852, bad both as to quantity and quality of produce; 1856, quantity fair, but quality indifferent; 1858, quantity moderate, quality above the average; 1863, good as to quantity and quality. As to manuring the conditions were unmanured; farmyard manure had ammonium salts alone; ammonium salts and superphosphate; ammonium salts, superphosphate and soda salt; ammonium salts, superphosphate and potash salt; ammonium salts, superphosphate and magnesia salt; and, finally, a mixture of the last three. In the third series of analyses the manures employed were almost the same as those used in the second series, but the analyses relate to a period of twenty consecutive years. The results confirm those obtained in series I. and II. It is seen that the amount of mineral constituents taken up by the plant over a given area depends very directly on the amounts in available condition within the soil and that while the quantity stored in the grain is nearly uniform, the amounts remaining in the straw have a very obvious connection with the supply or exhaustion in the soil. The influence of season is also well marked. The composition of the grain, as to its mineral constituents, seems only to vary with the manure when there is a very abnormal deficiency of one or more constituents, having regard to the amount of growth which is induced by the liberal supply of others. The paper is very lengthy (over 70 pages), and contains eighteen tables of analyses. The authors promise in a future communication to give a similar series of analyses of ashes from barley, leguminous crops, root crops, potatoes, and the mixed herbage from grass land.

The President complimented Dr. Gilbert on the lucidity with which he had communicated the paper; it seemed to him a most interesting fact brought out by this remarkable series of ash determinations, that the composition of the grain should be so uniform.

Mr. T. Farrington gave an instance of the importance of the season with reference to the action of manure with potatoes. In a wet season the addition of kainit was without beneficial influence on the crop, but in a dry season its use was found to be very beneficial; he had also noticed that nitrates had at first more effect than ammonium salts in promoting growth.

Mr. Lloyd was much impressed with the fact that the mineral constituents in a poor crop were relatively larger than in a good crop. The roots probably gathered the mineral constituents independently of the season, and so if the weather was bad and the organic constituents were not formed, the amount of mineral matter would be apparently increased. As the straw seemed to vary more or less with the manure applied, an analysis of the straw ash might perhaps serve as an index of the mineral constituents wanting in the soil.

Dr. Gilbert said that at present it would be difficult to differentiate the mineral constituents of the straw ash. There was no doubt that in bad seasons the maturation of the grain was sluggish and the starch formation was imperfect, and so the percentage of mineral matter was raised.

On the Analysis of Shotley Bridge Spa Water. By H. Peile.—Apparently only one analysis, and that incorrect, has been made of this water. The author has obtained the following numbers indicating grams per litre:—Barium chloride, 0·0569, ammonium chloride, 0·0042, calcium chloride, ·2632, magnesium chloride, 0·0437, lithium chloride, 0·0565, potassium chloride, 0·0513, sodium chloride, 1·7333, calcium bicarbonate, 0·3964, ferrous bicarbonate, 0·0155, magnesium bromide, 0·0075, traces of magnesium bicarbonate and iodide, manganous bicarbonate, silica, phosphates, albumenoid ammonia. The water tastes strongly of iron.

The Society then adjourned to March 6, when a paper by Drs. Armstrong and Miller, "On the Hydrolysis of Sulpho Compounds" will be read.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above Association, held on Wednesday, February 13, Mr. Parkinson (President), in the chair, a paper on the "Human Eye" was read by W. J. Frankish, M.R.C.S.E.

The lecturer divided his subject into sections. He drew attention to the orbit, the strength of its margins and how well it preserved the eye from injury, as witnessed by the number of persons who at some time in their life have been wounded or contused in the region of the eye, without that organ being injured. How useful and necessary are the eyelids, which by their action are continually wiping off the particles of dust which settle on the cornea, was demonstrated. By means of diagrams he illustrated the cause of long and short sightedness, and showed the action of the muscles which move the eye. The lecturer also by the use of diagrams showed the action of the lachrymal gland, its position, etc., and how the tears are carried off. In explaining the anatomy of the eye the author compared it with the photographic camera and showed the superiority of the eye over any mechanical apparatus by its adaptability to any distance and to any sized picture. There was not time to enter into the phenomena of vision and illusions of sight.

A long discussion followed, in which the President, Messrs. Braithwaite, Burnett, Glew, Hartridge, Parker and Millhouse took part, after which a cordial vote of thanks to Mr. Frankish for his valuable and interesting paper was proposed by Mr. Parker and seconded by Mr. Millhouse, and carried unanimously.

Mr. Frankish having replied, the meeting was adjourned.

Parliamentary and Law Proceedings.

Prosecution under the 17th Section of the Pharmacy Act.

At the Oldham Police Court, on Wednesday, John Wood, 125, Manchester Street, was summoned for illegally selling poisons.

The summons was taken out by Alfred S. Wright, the Assistant Secretary of the Chemists and Druggists' Trade Association of Great Britain. Mr. Porter (Glaisyer and Porter, solicitors, Birmingham) was for the prosecution, and Mr. Hodgkinson for the defence.

Mr. Porter said the summons was taken out under the 17th section, 31 and 32 Victoria, chapter 131, entitled An Act to Regulate the Sale of Poisons, which stated that it was unlawful to sell poisons, wholesale or retail, unless the box, bottle, or vessel, in which such poison was contained was distinctly labelled "poison," with the name and address of the seller, and the name of the poison, and any person convicted under the Act was liable to a penalty not exceeding £5 for the first, and £10 for the second and each subsequent case. The facts of the case were as follow:—On the 14th inst. the Assistant Secretary, from representations made to him, came to Oldham, and went to defendant's shop, and among other things asked for a pennyworth of oxalic acid, which was supplied in a packet, which bore a label on which was the word "poison," but neither the seller's name, or the name of the poison. The case was of great importance to the public, as scarcely a paper could be taken up that did not contain an account of some case of accidental poisoning, in consequence in many cases of the poisons being insufficiently labelled. The object of bringing the case before the public was to show reckless traders that they could not controvert the Act of Parliament in this manner.

Alfred Wright, Assistant Secretary of the Chemists and Druggists' Association of Great Britain, stated that on the 14th inst. he went to 125, Manchester Street, the name over the window being "Wood." He went into the shop and asked for a pennyworth of oxalic acid, and one or two other things. It was handed to him in the packet produced, which had on simply the word "Poison," without the name and address of the seller or the name of the particular poison. The packet was in the same state as when purchased, excepting that a portion had been taken out for analysis.

Mr. Hodgkinson: Is that poison?

Mr. Porter: Most decidedly.

Mr. Hodgkinson: You have not proved it.

The Complainant, cross examined by Mr. Hodgkinson, said: I went into other shops in Oldham, but have not taken out any other summonses. I first asked for a quarter of a pound of linseed meal, then for two pennyworth of laudanum. He supplied the linseed meal, but said he did not keep laudanum. I asked for a pennyworth of rottenstone. That was not poison. I asked for a pennyworth of oxalic acid. He did not say he would not supply it. The defendant remarked, "You must be careful with it; it is poison." I said "I know it." He did not say he was a wholesale dealer, and that he supplied it only in large quantities to wholesale dealers. I have not been prejudiced by the purchase. I do not believe that anyone has been prejudiced by the purchase. The defendant asked if the oxalic acid was for cleaning harness. I said it was for cleaning brass.

Joseph Pendleton, poor-rate collector, said the rates for the premises were paid by the defendant.

Mr. Hodgkinson characterized the prosecution as paltry, and said the complainant went into the shop for the purpose of trapping the defendant. He said he would call the defendant.

The Clerk: He cannot be called, as it is a criminal offence.

Mr. Hodgkinson: It was allowed in O'Donnell's case.

The Clerk: It was a favour; not a right.

Mr. Hodgkinson said he would withdraw from the case, so that the defendant might make his own statement.

The defendant then said that he informed the complainant that he did not sell oxalic acid except by wholesale. The complainant asked for a small quantity for the purpose of cleaning taps. He (defendant) was in a hurry to catch a train, and he put a small quantity in a piece of paper, attaching the word "Poison." He received a penny for the poison produced.

The Bench inflicted a fine of £1, with the ordinary court costs.

Mr. Porter asked for extra costs, observing that the proceedings were taken for the benefit of the public. There had been a couple of journeys by the Assistant Secretary to Oldham, and extra expense for a solicitor's fees. They heard that in Oldham there had been a lot of illegal trading going on.

Mr. Hodgkinson said the Bench had already done that which would meet the justice of the case, considering the circumstances under which the poison was obtained—under false pretences.

Mr. Porter objected to the latter statement.

The Bench: Obtained for the purpose of the prosecution. They declined to alter their decision.—*Oldham Daily Standard.*

Poisoning by Chloral Hydrate in an Infirmary.

An inquest was held at the Gloucester Infirmary on Tuesday afternoon on the body of Anne Frost, who died very suddenly on the previous Friday. The house surgeon stated that Dr. Washbourn, senior physician, prescribed for deceased a sleeping draught. The mixture was to contain syrup of chloral hydrate, and each draught to contain 1 drachm. In such a dose there would be 10 grains of chloral hydrate. The prescription was dictated by Dr. Washbourn and taken down by Mr. Ancrum, who left out the word "syrup." The difference in the amount of chloral hydrate is 60 grains instead of ten. The prescription as taken down by Mr. Ancrum was evidently a mistake. Mr. Ancrum had been a pupil at the infirmary six or seven months The woman died a quarter of an hour after the dose. He should consider she died from syncope, brought about by the draught administered and the condition of her heart and lungs. The draught contained chloral hydrate 1 drachm, instead of syrup of chloral hydrate 1 drachm. Mr. A. P. Carter, surgeon, practising in Gloucester, said such a dose, in his opinion, would be almost certain to cause death. The inquest was resumed yesterday, and other evidence having been taken, the Jury, after an hour's consultation, returned a verdict "That deceased came to her death owing to the administration to her by mistake at the infirmary of an excessive dose of chloral hydrate," and expressed their opinion that the system disclosed by the inquiry as existing at the infirmary, with reference to the dictating of prescriptions without any signature of a responsible medical officer being appended, was a very dangerous one, and one which ought to be remedied.—*Times.*

Correspondence.

The Benevolent Fund.

Sir,—I was pleased to see in last Saturday's Journal the "Local List of Subscribers to the Benevolent Fund," which should stimulate all our local secretaries to a renewed exertion on its behalf,—for even chemists are not exempt from the levelling process now going on, and it is not impossible that many who now do what they can to support the Fund may by adverse circumstances be led to seek its aid. Thence the necessity for a material increase in the number of subscribers. It is not cheering or satisfactory to see so many places of considerable importance raising scarcely the conventional guinea, among all the chemists and their assistants. The latter class seem to be overlooked to a large extent, although many would be pleased to show their sympathy with the aged and helpless of our brethren; whilst many of the former must be forgetful, indifferent, or perhaps have not been solicited. At all events an appeal throughout the country (not as a special effort merely, but) to permanently increase the annual subscriptions would be the means of making some cheerless homes somewhat brighter and the last years of not a few somewhat more comfortable, whilst the personal sacrifice, as an annual subscription, would not be great.

I hope that this suggestion may be of some use in the interest of the "Fund."

NOTE ON LOGWOOD AS A TEST FOR METALS.*

BY ARTHUR WEDDELL.

For some years past I have been accustomed to examine potable waters for metallic impurities by means of the alteration produced in the colouring matter of logwood, and as it furnishes a delicate and convenient means of detecting their presence I have thought it worth bringing before this Society. When logwood is digested with alcohol an extract of a rich yellow colour results, and this colour is not changed on dilution with a pure, freshly distilled water. When added to ordinary samples of water, which contain calcium carbonate in solution, the yellow colour is changed to a beautiful rose red, or if a metal be present to blue.

These changes are accounted for in the following manner:—Hæmatoxylin, the ordinary colouring matter of logwood, is converted by oxygen, especially in the presence of alkalies, into an oxidized product known as hæmatëin, which gives a blue precipitate with salts of iron, lead, copper and many other metals, or if the solution be extremely dilute, a blue coloration only. This reaction is so delicate that 1 part of lead in 100,000 parts of water is easily detected, and with care 1 part in 200,000.

These changes do not occur in acid solutions. The method of using the test is extremely simple and consists in the addition of a few drops of a very dilute tincture of logwood to the sample under examination, care being taken that the quantity added is not too great, as a trace of metal may be thus overlooked, owing to the difficulty of observing the change of colour in presence of a large excess of red colouring matter.

My own practice is to prepare an alcohol extract of logwood (strength 1 in 100) by maceration and to note how much of this is required to produce a distinct rose colour in 100 c.c. of distilled water rendered faintly alkaline with ammonium carbonate, or in 100 c.c. of hard water free from metals.

This quantity of logwood solution is next added to 100 c.c. of the water under examination, and the two tubes compared. If a rose colour is developed, metals are absent, while a blue colour indicates their presence.

More logwood may afterwards be added to each tube and the progressive differences noted, the blue colour increasing in depth, or to a precipitate if much lead be present.

By adding sufficient lead solution of known strength to the pure water, so as to imitate the colour in the second tube, as in Nesslerizing, an approximate idea of the amount of lead may be obtained, when it is known that no other metal is present; but I have not considered the reaction worth experiment in this direction, because the exact comparison is somewhat difficult and can hardly reach scientific accuracy.

The presence of free acids interferes with the reaction, and these, if present, must therefore be carefully neutralized and a slight excess of alkali added. Free carbonic acid gas should be removed by boiling, but I have never met with drinking water that required such treatment.

A variety of applications of this test will suggest themselves. Some years ago I recommended a convenient means of testing glycerine for lead and other metals, by adding the glycerine to water coloured red with logwood. Soda water may be examined by boiling to free from CO_2 and adding the logwood. Lemonade by adding a slight excess of pure alkaline carbonate and boiling. The mineral and vegetable acids may be examined by neutralizing carefully and adding the solution to water coloured red with logwood.

My attention was first attracted to this test by observing that distilled water stored in a metal cistern when used to dilute a logwood tincture turned it to a dirty greenish colour, and when this was mixed with tap water it turned blue. On examining the distilled water by the ordinary method, with SH_2, the presence of lead was detected, it having been dissolved from the solder used in the joints and in fixing the tap. As I have since met with this same condition of storage and impurity I think it would be well for those who store distilled water in such a manner to ascertain the absence of lead before using it.

THE CHEMICAL COMPOSITION AND PROPERTIES OF A CRYSTALLINE PRINCIPLE OBTAINED FROM JAMBOSA ROOT.*

BY A. W. GERRARD, F.C.S.,

Teacher of Pharmacy to University College.

The roots from which the principle under notice was extracted were handed to me in the summer of 1883 by Dr. Murrell, who received them from Messrs. Park, Davis and Co., with the following information:—

"The plant yielding these roots is probably the *Myrtus Jambosa*, L. (*Jambosa vulgaris*, DC.), cultivated on St. Maurice. The fruit has the circumference of a medium sized pear, a smell reminding of roses." In the same communication the plant is also mentioned as the "*Myrtus Jambosa Malacensis*, Spr. Is at home in India and Otaheiti. The fruit is known as the rose apple, is frequently eaten, and the decoction of the bark used as an astringent in dysentery, gonorrhœa and leucorrhœa."

Since I received the root it has been figured in the *Therapeutic Gazette*, and examined and reported on by Dr. A. B. Lyons, who throws some doubt on a statement that it is the root of *Eugenia Jambosa*, and gives his opinion that the root and stem in general aspect resemble plants of the order *Piperaceæ*. Dr. Lyons also names his drug "jambu assu," stating that it is indigenous to Brazil; but that name is applied in Chernoviz's 'Medical Formulary of Brazil' to *Spilanthes oleracea*, the plants of which genus are mostly smooth annual branching weeds, and would scarcely produce roots 10 to 15 millimetres in diameter, the size of jambosa roots. It may turn out that the name "jambosa" is a generic one, used in the Brazils for drugs of the same character; hence its application to both the plants mentioned. I have been enabled, through the kindness of Mr. E. M. Holmes, to examine some flowers of *Spilanthes oleracea*; they yielded me an oleoresin with properties similar to one obtained from jambosa, both being powerful sialagogues.

Dr. Lyons's examination of the root demonstrated

* Read at an Evening Meeting of the Pharmaceutical Society, March 5, 1884.

that it contained a neutral crystalline principle, an alkaloid, a peculiar acid, and an oleoresin. An independent examination of my own gave similar results, except that I did not notice the alkaloid. I since find it is present, but the quantity is so minute that its study is not worth following.

The extraction of the crystalline principle, which is found only in the bark of the root, is extremely easy. My process was as follows:—The bark was separated from the root, finely powdered and percolated with ether; the ether on evaporation gave an abundant crop of crystals, which by washing with ether and again crystallizing from ether were obtained perfectly white.

Properties of Crystals.—They are white and tasteless, melting at 77° C., becoming solid at 60° C.; soluble in cold ether, alcohol, and chloroform, and in hot petroleum ether. They are insoluble in cold water, but soluble on boiling, separating in crystals on cooling. With strong sulphuric acid they yield a bright green colour, soon passing to a deep reddish-brown. With strong nitric acid they react violently, giving off nitrous fumes and forming an orange coloured liquid, from which water precipitates a new compound. They gave none of the reactions of a glucoside, neither do they possess the character of weak resin acids.

Analysis.—Before combustion the crystals were submitted to fractional crystallization from various fluids; the various fractions proving of uniform composition the product was assumed to be pure. By exposure to dehydrating agents it scarcely lost weight.

Four combustions for carbon and hydrogen were made, giving as the average 60·585 per cent. C, and 7·584 per cent. H. Nitrogen being present it was twice estimated by the absolute method, and after the various corrections gave 7·2 per cent. N, leaving a difference of 24·631 O. These figures allow the construction of the formula $C_{10}H_{15}NO_3$, the theoretical percentages of which I have placed for comparison with those found—

	Analysis.	Theory.
C	60·585	60·91
H	7·584	7·6
N	7·2	7·1
O	24·631	24·39
	100·000	100·00

The name I propose for this substance is jambosin. Therapeutically it is of very little interest, as I have taken several doses without any apparent effect. The active principle of jambosa is no doubt to be found in the oleoresin, which is a powerful sialagogue, and deserving of further research.

[*The discussion on this paper is printed at p.* 728.]

A NEW REACTION AND TEST FOR ATROPINE AND THE MYDRIATIC ALKALOIDS.*

BY A. W. GERRARD, F.C.S.,

Teacher of Pharmacy to University College.

Whilst studying the behaviour of atropine towards mercuric chloride I was somewhat surprised to find on mixing hot alcoholic solutions that they gave a yellow precipitate, which on boiling became red. On diluting the mixture with water a further amount of yellow precipitate was obtained, which also changed to red on boiling.

The precipitate separated, washed and dried, was found on analysis to be mercuric oxide, with a small trace of mercurous oxide.

The reaction representing the first change can be shown by the following equation:—

$$2C_{17}H_{23}NO_3 + H_2O + HgCl_2 = 2C_{17}H_{23}NO_3HCl + HgO.$$

In addition to the above reaction, I find that a second one takes place simultaneously. This second reaction is between the atropine hydrochlorate and two more molecules of the mercuric salt, yielding the following combination:—

$$\underset{\text{Atropine hydrochlorate.}}{C_{17}H_{23}NO_3HCl} + \underset{\text{Mercuric chloride.}}{2HgCl_2} =$$

$$\underset{\text{Dimercuric chloride atropine hydrochlorate.}}{C_{17}H_{23}NO_3HCl(HgCl_2)_2}$$

On cooling and setting aside a few hours this compound separated in tufts of crystalline plates.

It is seen in the first equation that water is essential to the production of the mercuric oxide, this I have proved by mixing absolute alcoholic solutions, also ethereal solutions of the two salts, but no reaction took place until water was added. As commercial alcohol contains traces of water a slight reaction may follow its use. The above experiment was repeated on hyoscyamine, daturine, duboisine, and homatropine, with the same result, thus affording additional proof of the unity of the mydriatic alkaloids.

The composition of the above double salt was established as follows:—500 milligrammes of the carefully dried salt were dissolved in water, and potassic hydrate added in slight excess; the resulting precipitated mercuric oxide was separated, dried and weighed, then calculated as Hg: it gave 228 milligrammes or 45·6 per cent. The filtered solution and washings from the mercuric oxide were faintly acidified with acetic acid, and the chlorine estimated with argentic nitrate, using potassic chromate as indicator; I thus obtained 99·4 Cl or 19·9 per cent. The difference of the above quantities being assumed as atropine would leave 34·5 per cent. for that body, so that analysis and formula percentages may be thus compared:—

	Percentages. Theory.	Percentages. Found.
Mercury	46·1	45·6
Chlorine	20·4	19·9
Atropine	33·3	34·5

To further prove these results another analysis was made as follows:—500 milligrammes of the salt were dissolved in water, and treated with H_2S in excess, and the precipitated mercuric sulphide washed, dried and weighed gave mercury equalling 45·9 per cent. The filtrate and washings were warmed for some time until quite free from H_2S; it was then made neutral with potassic hydrate and the chlorine estimated as above. I now obtained 20·7 per cent. Cl. This result thus confirms the previous analysis.

In addition to the foregoing, I have prepared hydrochlorate of atropine, and treated it with two molecules of $HgCl_2$, and thus obtained the same double compound.

Expecting to find other alkaloids to react in a similar manner, the same test was applied to as many alkaloids as were at my disposal; in no case did I obtain a red precipitate. The following were examined:—Strychnia, brucia, morphia, codeia,

* Read at an Evening Meeting of the Pharmaceutical Society, March 5, 1884.

veratria, aconitia, conia, gelseminia, caffeia, theia, cinchonia, cinchonidia, quinia and quinidia. With most of these I obtained white precipitates; the codeia and morphia became pale yellow on boiling; in many cases crystals of apparently new combinations separated.

For practically working the test, I recommend the following procedure:—To a small portion of atropine in a test tube, add about 2 c.c. of a 5 per cent. solution of mercuric chloride in 50 per cent. alcohol and warm gently; the precipitate will at once appear, and become brick-red in colour. Like most alkaloidal reactions, I find there are certain limiting conditions necessary for the success of the test. It does not answer in dilute solutions, neither does it turn out well if the atropine be added to the mercury, but working as I have described the reaction is strongly marked.

In forensic analysis the above test will be of value, as hitherto no reliable chemical test for atropine has been known. This communication also shows, that under certain conditions, atropine, contrary to the general statement, behaves towards mercuric chloride not like ammonia, but similar to the hydrates of the alkali metals.

[*The discussion on this paper is printed at p.* 729.]

TIN IN CANNED FOODS.*

BY PROFESSOR ATTFIELD, F.R.S., ETC.

From time to time during the past twelve years paragraphs have appeared in newspapers and other periodicals tending in effect to warn the public at least against the indiscriminate use of canned foods. And whenever there has been any foundation in fact for such cautions, it has commonly rested on the alleged presence and harmfulness of tin in the food. At the worst the amount of tin present has been absurdly small, affording an opportunity for one literary representative of medicine to state that before a man could be seriously affected by the tin, even if it occurred in the form of a compound of the metal, he would have to consume at a meal ten pounds of the food containing the largest amount of tin ever detected.

But the greatest proportions of tin thus referred to are, according to my experiments, far beyond those ever likely to be actually present in the food itself in the form of a compound of tin; present, that is to say, on account of the action of the fluids or juices of the food on the tin of the can. Such action and such consequent solution of the tin, and consequent admixture of a possibly assimilable compound of tin with the food, in my opinion, never occurs to an extent which in relation to health has any significance whatever. The occurrence of tin, not as a compound but as the metal itself, is, if possible, still less important.

During the last fifteen years I have frequently examined canned foods, not only with respect to the food itself as food and to the process of canning, but with regard to the relation of the food to, or the influence if any of the metal of, the can itself. So lately as within the past two or three months I have examined sixteen varieties of canned food for metals, with the following results:—

* Read at an Evening Meeting of the Pharmaceutical Society, March 5, 1884.

Name of article examined.	Decimal parts of a grain of tin (or other foreign metal) present in a quarter of a pound.
Salmon	none
Lobsters	none
Oysters	0·004
Sardines	none
Lobster paste	none
Salmon paste	none
Bloater paste	0·002
Potted beef	none
Potted tongue	none
Potted "strasbourg"	none
Potted ham	0·002
Luncheon tongue	0·003
Apricots	0·007
Pears	0·003
Tomatoes	0·007
Peaches	0·004

These proportions of metal are, I say, undeserving of serious notice. I question whether they represent more than the amounts of tin we periodically wear off tin saucepans in preparing food—a month ago I found a trace of tin in water which had been boiled in a tin kettle—or the silver we wear off our forks and spoons. There can be little doubt that we annually pass through our systems a sensible amount of such metals, metallic compounds, and other substances that do not come under the denomination of food; but there is no evidence that they ever did or are ever likely to do harm or occasion us the slightest inconvenience. Harm is far more likely to come to us from noxious gases in the air we breathe than from foreign substances in the food we eat.

But whence come the much less minute amounts of tin—still harmless be it remembered—which have been stated to be occasionally present in canned foods? They come from the minute particles of metal chipped off from the tin sheets in the operations of cutting, bending or hammering the parts of the can, or possibly melted off in the operations necessary for the soldering together of the joints of the can. Some may, perhaps, be cut off by the knife in opening a can. At all events I not unfrequently find such minute particles of metal on carefully washing the external surfaces of a mass of meat just removed from a can or on otherwise properly treating canned food with the object of detecting such particles. The published processes for the detection of tin in canned food will not reveal more than the amounts stated in the table, or about those amounts, that is to say a few thousandths, or perhaps two or three hundredths of a grain, if this precaution be adopted. If such care be not observed the less minute amounts may be found. I did not detect any metallic particles in the twelve samples of canned food just mentioned, but during the past few years I have occasionally found small pieces of metal, perhaps amounting in some of the cases to a few tenths of a grain per pound. Now and then small shot-like pieces of tin or possibly solder may be met with. But no one has ever found, to my knowledge, such a quantity of actual metallic tin, tinned iron, or solder, as, from the point of view of health, can have any significance whatever.

The largest amount of tin I ever detected in actual solution in food was in some canned soup, containing a good deal of lemon juice. It amounted to only three-hundredths of a grain in half a pint of the soup as sent to table. Now, Christison says that quantities of

18 to 44 grains of the very soluble chloride of tin were required to kill dogs in from one to four days. Orfila says that several persons on one occasion dressed their dinner with chloride of tin, mistaking it for salt. One person would thus take not less than 20 to 30 grains of this soluble compound of tin. Yet only a little gastric and bowel disturbance followed and from this all recovered in a few days. Pereira says that the dose of chloride of tin as an antispasmodic and stimulant is from $\frac{1}{16}$ to $\frac{1}{4}$ a grain repeated two or three times daily. Probably no article of canned food, not even the most acid fruit, if in a condition in which it can be eaten, has ever contained, in an ordinary table portion, as much of a soluble salt of tin as would amount to a harmless or useful medicinal dose.

Metallic particles of tin are without any effect on man. A thousand times the quantity ever found in a can of tinned food would do no harm.

Food as acid as, say, ordinary pickles, would dissolve tin. Some manufacturers once purposed using tin stoppers to their bottles of pickles. But the tin was slowly dissolved by the acid of the vinegar. These pickles, however, had a distinctly nasty "metallic" flavour. The idea was abandoned. Probably any article of food containing enough tin to disagree with the system would be too nasty to eat. Purchasers of food may rest assured that the action taken by this firm would be that usually followed. It is not to the interest of manufacturers or other vendors to offend the senses of purchasers, still less to do them actual harm; even if no higher motive comes into force.

In the early days of canning it is just possible that the use of "spirits of salt" in soldering may have resulted in the presence of a little stannous, plumbous, or other chloride in canned food; but such a fault would soon be detected and corrected, and, as a matter of fact, rosin-soldering is to my knowledge more generally employed —indeed, for anything I know to the contrary, is exclusively employed — in canning food. Any rosin that gained access would be perfectly harmless. It is just possible also that formerly the tin itself may have contained lead, but I have not found any lead in the sheet tin used for canning of late years.

In conclusion: 1. I have never been able to satisfy myself that a can of ordinary tinned food contains even a useful medicinal dose of such a true soluble *compound* of tin as is likely to have any effect on man. 2. As for the metal itself, that is the filings or actual metallic particles or fragments, one ounce is a common dose as a vermifuge; harmless even in that quantity to man, and not always so harmful as could be desired to the parasites for whose disestablishment it is administered. One ounce might be contained in about four hundredweight of canned food. 3. If a possibly harmful quantity of a soluble compound of tin be placed in a portion of canned food the latter will be so nasty and so unlike any ordinary nasty flavour, so "metallic" in fact, that no sane person will eat it. 4. Respecting the globules of solder (lead and tin) that are occasionally met with in canned food, I believe most persons detect them in the mouth and remove them, as they would shots in game. But if swallowed they do no harm. Pereira says that metallic lead is probably inert, and that nearly a quarter of a pound has been administered to a dog without any obvious effects. He goes on to say that as it becomes oxidized it occasionally acquires activity, quoting Paulini's statement that colic was produced in a patient who had swallowed a leaden bullet. To allay alarm in the minds of those who fear they might swallow pellets of solder I may add that Pereira cites Proust for the assurance that an alloy of tin and lead is less easily oxidized than pure lead. 5. Unsoundness in meat does not appear to promote the corrosion or solution of tin. I have kept salmon in cans till it was putrid, testing it occasionally for tin. No trace of tin was detected. Nevertheless, food should not be allowed to remain for a few days or even hours in saucepans, metal baking pans, or opened tins or cans, otherwise it *may* taste metallic. 6. Unsound food, canned or uncanned, may of course injure health, and where canned food really has done harm, the harm has in all probability been due to the food and not to the can. 7. What has been termed idiosyncrasy must also be borne in mind. I know a man to whom oatmeal is a poison. Some people cannot eat lobsters, either fresh or tinned. Serious results have followed the eating of not only oatmeal or shell-fish, but salmon and mutton; *hydrate* (misreported *nitrate*) of tin being gratuitously suggested as being contained in the salmon, in one case. Possibly there were cases of idiosyncrasy in the eater, possibly the food was unsound, possibly other causes altogether led to the results, but certainly, to my mind, the tin had nothing whatever to do with the matter.

In my opinion, given after well weighing all evidence hitherto forthcoming, the public have not the faintest cause for alarm respecting the occurrence of tin, lead, or any other metal in canned foods.

[*The discussion on this paper is printed at p.* 730.]

THE STEAROPTEN OF OIL OF PATCHOULY.*

BY HENRY C. C. MAISCH.

Patchouly camphor, a homologue of borneol, as obtained from the oil was in pieces of various size and form, mostly belonging to the hexagonal class of crystals. The colour ranged from light yellow, probably from adhering or enclosed oil, to colourless.

In order to purify the camphor, it was dissolved in alcohol. This solution did not crystallize although evaporated to a syrupy consistency. The alcohol was completely driven off, and the residue dissolved in ether, from which solution it deposited after several times recrystallizing in colourless truncated hexagonal prismatic crystals.

The fusing points of both the crude and the recrystallized camphor were determined. A small quantity was put on some mercury in a beaker glass in which a thermometer was suspended, the mercury covering the bulb. A slow heat was then applied, the mercury in the thermometer rising slowly. The melting point of the recrystallized camphor was found between 55° and 56° C., coming near that determined by Gal in 1869 (*Compt. Rend.*, lxviii., 406), who gives it as 54°–55° C., while another author, de Montgolfier (*Ber. Deutsch. Chem. Ges.*, 1877, 374), gives it as 59° C. The melting point of the crude camphor, determined upon mercury as stated above, was found between 57°–58° C., or about 2° C. higher than that of the recrystallized. The latter again solidified when cooled to between 48° and 49° C., but the congealing point for the crude camphor is between 54° and 55° C. The boiling point determined by Gal, is given at 296° C., the specific gravity as 1·051 at 4·5° C., and the vapour density as 8·00 at 324° C.

THE LEGISLATIVE OUTLOOK.

THE progress of events during the last few days has disclosed the present intentions of the Government in respect to two questions upon which many pharmacists in this country are desirous that legislation should take place,—namely, the sale of poisons and the constitution of the Pharmacopœia Committee,—and it seems to us to be very regrettable that those intentions should prove to be of so limited or even negative a character. It is now about sixteen months since the Lords of the Privy Council, being made aware of serious defects in the existing law relating to the sale of poisons, expressed a wish that the Pharmaceutical Socicty should submit to them its views upon the subject in the form of a draft Bill amending the existing law in regard to the sale of poisons. This task was at once undertaken by the Council of the Pharmaceutical Society, and the result was the submission shortly afterwards of a draft Bill, with the provisions of which our readers are acquainted. The parliamentary session of 1883, however, passed away without the Government seeing its way to the introduction of a measure, and the proceedings in Parliament relating to the subject in the present session have hitherto consisted of an almost exact repetition of those of last year,—the introduction of a yet unprinted Bill relating to patent medicines containing poisons by a private member, and an announcement of the intention of the Goverment to deal with the general question. It was only natural, therefore, that the Council of the Pharmaceutical Society, having been induced to formulate its views, should endeavour to obtain some definite information as to the course intended to be taken by the Government, and the consequent correspondence, as laid before it at the meeting on Wednesday last, will be found on another page. It will be seen from this that the Government has decided to confine the Bill that it proposes to introduce to the question of the sale of poisons, and does not intend to include any amendments of the Pharmacy Act in relation to the status or organization of the Pharmaceutical Society.

It would seem, therefore, that little further can be done until the publication of the text of the Government Bill shows the exact official construction placed upon the somewhat vague phrase "amendments on the Pharmacy Acts in relation to the status or the organization of the Pharmaceutical Society." The Council would, however, appear to be quite warranted in expressing its regret at the general tenour of the information, and in stating its inability to see how it is possible to satisfactorily amend the law in regard to the sale of poisons without at the same time dealing with the amendment of the Pharmacy Acts. A superficial knowledge characteristic in amateur legislators, or a wilful blindness that refuses to recognize existing facts, may indeed suggest the entire dissociation of the two subjects; but the basis of the existing law in relation to poisons is too clearly stated to be ignored, and legislation that does not at least attempt to remedy the defects of the Pharmacy Acts and make them effectually operative will leave them less powerful for the public good than before. It is only necessary to refer to the preamble of the Act of 1868, where it is laid down that it is expedient for the safety of the public that persons keeping open shop for the selling of poisons should possess a competent practical knowledge of their business, tested by examination and put in evidence by registration, to show that even the internal arrangements affecting the efficiency of the corporation which performs this duty for the public, and to a greater degree the provisions relating to examination and registration, are worthy of revision when the general subject of poisons is under consideration. The Council, with its intimate knowledge of points in which the Act fails to fulfil the purposes for which it was passed, and the unforeseen subterfuges by which the provisions made in the interest of the public are daily evaded, would have proved sadly lax in the performance of the duty which at the invitation of the Privy Council it had undertaken had it not embodied as far as possible in the draft Bill the whole of the conclusions drawn from its experience. It can be easily understood, however, why the Government, which has had this question somewhat forced upon it by passing events, should in the present state of parliamentary business desire to keep the Bill which it proposes to introduce within the narrowest possible limits. Nevertheless, if it is intended to deal with the question of patent medicines containing poisons, as would seem to be implied in the answer recently given by MR. MUNDELLA to MR. WARTON, it will be difficult to steer clear of the Pharmacy Act altogether. Still, pending the appearance of the Bill, it will be hardly worth while to speculate upon its provisions. When it is published, however far it may come short of what may be considered legitimate expectations, it will be certain to receive the most careful consideration from the Council of the Pharmaceutical Society, and no doubt the suggestion as to laying the result of the Council's deliberations before the Government will be followed. It seems probable, however, that the Council may deem it advisable to embody in another Bill the provisions for which the Government declines to accept the responsibility, and we do not gather from the letter from the Privy Council that any official opposition would be offered to such a course.

On Monday the promised Government Medical Acts Amendment Bill was introduced into the House of Lords and read a first time, and on Thursday its second reading was taken. The Bill appears to be practically in the same form as it was left by the House of Commons at the end of last session, with the exception of an attempt to disarm opposition in one quarter by allowing the Scotch medical corporations to have five representatives on the Medical Council instead of three, as proposed last year. At any rate the clauses relating to the preparation of the British Pharmacopœia remain unaltered. The Bill still provides that the Medical Council shall from time to time cause to be published under its direction a book containing a list of medicines and compounds and the manner of preparing them, to be called the British Pharmacopœia, and that the exclusive right of publishing, printing and selling this work shall vest in the Medical Council. It seems a pity that apparently no heed should have been paid to the prayer of the large number of petitions presented in the closing days of the last session, both from members of the medical profession and pharmacists, asking that provision should be made to include among the members of the Committee charged with the preparation of the national Pharmacopœia a certain number of pharmaceutical chemists. There are some points in the Bill that have excited strong opposition, which may yet imperil its passage; but concerning this request for the proper representation of pharmacists in the Committee entrusted with the duty of preparing their special text-book, we have not yet seen expressed in print a single dissentient opinion. If it had not been that, as before mentioned, the Bill bears the marks of concession in favour of a demand that although strongly supported, was by no means undisputed, it might have been thought that possibly it had not been deemed consistent with the policy ruling the conduct of the Bill to accord even this unanimous request apart from a decision in Parliament. For some inscrutable reason, however, the request not ostensibly disputed has up to the present been ignored, whilst one concerning which there was considerable difference of opinion has been conceded. It seems probable, therefore, that it may become necessary to take active steps to bring the subject under the special attention of Parliament, even before it leaves the House of Lords. In any case, the progress of the Bill will be carefully watched, and we do not doubt that, should it appear necessary in order to secure the object in view, the Council of the Pharmaceutical Society will take the proper steps to bring its legitimate influence to bear, and that the pharmacists throughout the country will, as last year, unite to exercise a constitutional pressure upon their representatives in the House of Commons.

It will be seen from an advertisement on another page that on Wednesday next, at noon, a meeting will be held at 17, Bloomsbury Square, to make arrangements for the usual Annual Dinner of the members of the Pharmaceutical Society and their friends in connection with the Annual Meeting in May. Gentlemen who are willing to become Stewards, but who will be unable to attend the meeting on Wednesday, are recommended to communicate their wish upon the subject at once to Mr. Richard Bremridge.

* * *

The Medical Acts Amendment Bill, which was read a first time in the House of Lords on Monday and a second time on Thursday, is to be considered in Committee on Thursday, the 20th inst.

* * *

On Wednesday last a decision was given in the Court of Appeal of considerable importance in relation to the registration of names as trade marks. The litigation commenced in an attempt made by a firm of oil manufacturers to restrain a competitor from using the term "valvoline," which they had registered as a trade mark used by them before the passing of the Trade Marks Act, 1875. It seems to have been admitted that the word had been used by the plaintiffs as applying to a particular article of their manufacture, and that it had been even used in combination with a device as a distinguishing trade mark. But a previous adverse decision had led to the registration of the term alone. The defendant therefore contended that as the word "valvoline" *simpliciter* had never been used as a trade mark, but only as a descriptive name, the registration of it as a trade mark was bad, and in a cross action he applied that the Registrar of Trade Marks should be ordered to remove it from the Register. This application Mr. Justice Pearson granted, notwithstanding that it was urged that even if the trade mark had been originally bad, it had become good through the lapse of five years since registration, and it was against this decision that appeal was made. The Lord Chancellor, in his judgment, in which Lord Justices Cotton and Fry concurred, said that if the word "valvoline" had been used as a trade mark in this country before the passing of the Act its registration would have been good. A descriptive word might be used as a trade mark, but if the article to which it applied was such that anybody might make and sell it, no right to the word could be got except by user as a trade mark. In this case no such user as a trade mark had been proved, and the original registration under the Act of 1875 having been therefore defective, Mr. Justice Pearson's decision that the name should be removed from the Register of Trade Marks was right.

* * *

Mr. Consul Robertson in a recent trade report, whilst declining to introduce controversial matters, refers to the fact that complaints have reached him as to the manner in which the Japanese Government laboratories are worked to the detriment of importers of drugs, medicines and chemicals. It has been urged upon him that the standard of purity sought to be imposed on these articles upon their entry into Japan is too high when compared with that in force in other countries, and that manufacturers find it difficult to meet the requirements of the Japanese examiners in this respect. We may mention that we recently heard of an instance of this in the stoppage at the custom house of a consignment of sodium benzoate, on the ground that it did not answer to the German Pharmacopœia test for benzoic acid in the reduction of a permanganate solution, which, as is known, is dependent upon the presence of an impurity in the sublimed acid.

* * *

The *Pharmaceutical Record* says that among the tricks of trade that have recently come to light in the United States is the filling of ginseng root with lead. It may be hoped that the "heathen Chinee," who are the chief consumers of this drug in that country, will show a proper appreciation of this application of the resources of civilization.

* * *

The Bill for the reorganization of the inspection of pharmacies in France, to which we referred recently, has been sent to the Committee charged with the Pharmacy Bill, which is considered to be equivalent to shelving it.

* * *

The publication of a new edition of the French Codex would appear to be imminent, as an official decree has appeared making the "new *Codex Medicamentarius, Pharmacopée Française,*" compulsory upon French pharmaciens from the 15th of the present month.

* * *

News has been received that on Friday, the 29th ult., the chemical works in Philadelphia, belonging to Messrs. Powers and Weightman, the large quinine manufacturers, were destroyed by fire. The value of the property destroyed has been estimated to exceed one million dollars, consisting largely of cinchona bark and manufactured products. The firm were the largest holders of quinine in the United States, and one result of the enormous destruction was that the price of bark in the American market immediately went up 50 per cent., and quinine rose from one dollar forty cents to two dollars per ounce.

* *

The Victoria Pharmaceutical Register published in January last, a copy of which has just been received, contains 683 names, showing an increase of 14 as compared with the previous Register.

* * *

The first meeting for the reading of papers of the newly established Glasgow and West of Scotland Section of the Society of Chemical Industry will be held in the Rooms of the Philosophical Society, Bath Street, Glasgow, on Tuesday next, at 8 p.m. The papers to be read are on "The Effect of Temperature in Dyeing," by Professor Mills and Mr. Rennie; "The Production of Ammonia from the Nitrogen of Minerals," by Mr. Beilby; and "The Distribution of the Gases in the Leaden Chamber," by Mr. Mactear. The Chairman of the Section is Mr. E. C. C. Stanford.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday next, March 13, at 8 p.m., when some "Further Notes upon the Synthesis of Uric Acid" will be read by Mr. J. S. Dymond, and a Report upon Pharmacology will be made by Mr. H. G. Greenish.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, March 12, at 9 p.m., when a paper on "Photography with the Microscope by aid of the Incandescent Electric Lamp" will be read by Mr. F. W. Branson, F.C.S.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, March 5, 1884.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Andrews, Borland, Bottle, Butt, Churchill, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

DIPLOMAS.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Haddock, James.
Randall, William Joseph.
Roberts, Edmund.
Wiggin, John Chinery.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Dolbear, John .... London.
Haddock, James .... Leigh.
Ord, Septimus William .... London.
Randall, William Joseph .... Wareham.
Roberts, Edmund .... Florence.
Wiggin, John Chinery .... Ipswich.

Chemists and Druggists.

The following chemists and druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Humble, John Mitchell .... Birmingham.
Seivwright, George .... Cullen.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society.

Adamson, William Stewart .... Aberdeen.
Bowering, John .... London.
Clarke, Herbert .... Dover.
Davies, Daniel .... Newcastle Emlyn.
Gill, William .... Nottingham.
Jenkins, Evan Edward .... Beeston.
Jevons, Wallis Byron .... Market Rasen.
Kerr, William Henry .... London.
Sinclair, Matilda Anne .... Llandudno.

ASSOCIATES.

The following, having passed the Minor examination and tendered (or paid as Apprentices or Students) their subcriptions for the current year, were elected "Associates" of the Society:—

Alderton, James .... Leamington.
Baker, Sidney George .... High Barnet.
Baker, Walter James .... Dorking.
Bates, John .... Bicester.
Black, James Watson .... Aberdeen.
Borthwick, Robert Waddell .... Bathgate.
Botham, William Bland .... Sheffield.
Burgess, William .... Runcorn.
Clarke, Richard .... Ruthin.
Davis, Frederick .... Oundle.
Farlow, James Southward .... London.

Fellows, Vincent Litchfield......London.
Heaver, Arthur William.........Norwich.
Jackson, George Granger ......Buxton.
Leach, John Pickering ....New Shoreham.
Mack, George Henry ....Holt.
Pomeroy, Francis Thomas ......South Petherton.
Potter, John Henry...............Nottingham.
Rawling, William John ....Devonport.
Richards, Thomas Coombs ......London.
Shallcross, Joseph Richard......Tunstall.
Smith, Samuel Henry ....Leamington.
Southwell, Charles Bullock......Bridgnorth.
Spratling, Walter................. Boston.
Taylor, George ....Edinburgh.
Wells, Arthur John...............Leamington.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Adams, Walter.......................Harrow.
Aspden, Henry.......................Over Darwen.
Batterbee, Robert Henry ......Lynn.
Birch, John ....Heywood.
Capon, Henry Charles............London.
Collett, William James ....Nantwich.
Davis, Herbert P....................Cardiff.
Farquhar, John McKelvie ......Greenock.
Farnworth, Walter ....Blackburn.
Gibson, George Wood ....Whitby.
Gibson, John W....................Richmond (Yorks).
Gould, Charles William ....London.
Graham, Joseph ....South Shields.
Green, Henry Selby...............Penzance.
Groves, Thomas ....Bridport.
Hallam, Samuel Robinson ......Burton-on-Trent.
Hodges, Arthur Lovell ....Sunderland.
Jones, Martin Llewelyn ....Aberdare.
Maddock, Herbert ....Manchester.
Morgan, William John ....St. Clears.
Morrison, Charles Orr............Sheffield.
Page, Percy Dodson...............Boston.
Parry, John .. ..Llangefni.
Peck, Edward ....Ely.
Peck, Ernest Saville ....Cambridge.
Phillips, George Edward.........Ashbourne.
Rookledge, Frederick ....Easingwold.
Slinn, Harry Edwin ....Burton-on-Trent.
Sloan, William Guley............Barking.
Thompson, George ....Knaresborough.
Webster, Edward..................Hull.
Widdowson, George William...Leicester.
Wilson, Alexander ....Greenock.
Wyllie, Harry Boak...............Kinghorn.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Restoration to the Register.

The name of the following person, who had made the required declarations and paid a fine of one guinea, was restored to the Register of Chemists and Druggists:—

Joseph Clempson, 42, South Street, Manchester Square, London, W.

Auditors' Report.

The Auditors' Report for the financial year ending December 31, 1883, was laid on the table.

The Conversazione.

It was resolved that the annual Conversazione be held on Wednesday, May 21, and the President, Vice-President, and Treasurer, with Messrs. Butt, Hills and Squire, were appointed a Committee to make the necessary arrangements.

The Secretary was also directed to apply to the Director of South Kensington Museum for permission to hold the gathering in that building.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

FREEHOLD INVESTMENTS.

The Council went into committee to consider this report and on resuming, the motion approving the report of the Committee was carried.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a former member, aged 77. Applicant had a grant of £10 in March, 1883; has to support a wife, aged 60, in delicate health, and two daughters. Herefordshire.

£10 to the widow of a member from 1856–59, during which time he was in business. Partially supports herself by needlework. Middlesex.

Two other applications had been deferred for further inquiries, and one from an applicant who had had six grants previously was not entertained.

The Vice-President moved the adoption of the report, which was carried unanimously.

The following statement had been submitted to the Committee by the Secretary:—

Benevolent Fund, 1883.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
January.	Day . . .	469	24	8	17
	Evening . .	155	16	1	7

Circulation of books.	Town.	No. of Entries. Country.	Total.
January	178	164	342

Carriage paid, £2 9*s.* 5½*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Pradel (P.), Le Gelsémium sempervirens, 1884.
From Prof. SOUBEIRAN.

Asclepiad (The), no. 1, 1884.
From Dr. B. W. RICHARDSON.

Morel (J.), Essai sur la Classification des Phrénopathies, 1884.

Nieuw Tijdschrift voor de Pharmacie in Nederland, Mei–Dec., 1883.

Pharmaceutisch Weekblad, 1883-4, 36 nos.
From Dr. J. MOREL.

Flora of British India, by Sir J. D. Hooker, etc., part 11, 1883.
From H. M. SEC. OF STATE FOR INDIA.

Midland Medical Miscellany, 1882-3.
From Mr. J. G. F. RICHARDSON.

Kügler (K.), Ueber das Suberin, 1884.
From Prof. FLÜCKIGER.

Geological and Natural History Survey of Canada, Report of progress for 1880-81-82, and Maps.
From the SURVEY.

The Committee recommended the purchase of the undermentioned works:—

New English Dictionary, edited by J. A. H. Murray, President of the Philological Society.

Encyclopædia Americana, 4 vols.

Dymock (W.), Vegetable Materia Medica of Western India.

Whitla (W.), Elements of Pharmacy, Materia Medica and Therapeutics, 2nd ed.

Curator's Report.

The Curator had reported the attendance in the Museum during January to have been:—

	Total.	Highest.	Lowest.	Average.
Morning .	572	44	2	21
Evening .	109	14	1	5

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimens of East Indian Red bark in very fine quills; two fine specimens of a new variety of Zanzibar aloes, recently offered in the London market as "Socotrine" aloes.
From Messrs. A. HILL AND SON.

Specimens of East Indian Calisaya bark in very fine quills. From Messrs CORBYN, STACEY AND CO.

Specimens of the following drugs from India:—Ekangi, Jonka, Sokai, Salpani, Setara, Parileamo.
From the DIRECTOR, ROYAL GARDENS, KEW.

Specimens of the seeds of *Abrus precatorius* in the pods. From Messrs. T. CHRISTY AND CO.

The further specimens of Cinchona bark from Darjeeling had been received. The collection consists of a fine series of herbarium specimens of *Cinchona officinalis, Ledgeriana succirubra*, and ten hybrids; also of young bark of the ten hybrids and powdered bark of the *Ledgeriana officinalis* and *succirubra* for analysis.

The specimens had been mounted and placed in the Museum.

The new show case for new drugs and recent donations to the Museum had been received.

The Professors had attended and reported satisfactorily on their respective classes.

Applications from Dundee University and from Mason's Science College, Birmingham, had been received, asking for copies of the Calendar, which it was recommended should be acceded to, and that in the former case the Journal also should be sent.

Mr. Rastrick, Portsea, and Mr. Robinson, York, had sent collections of autograph prescriptions, for which letters of thanks had been sent.

An estimate for new chairs for the Council room had been submitted, and it was recommended that the chairs be ordered.

Mr. Dunstan, the Assistant Lecturer in Chemistry, had applied for new and more modern diagrams for lecture purposes, and it was recommended that the matter be left in the hands of the President to carry out.

The Ballarat School of Mines and Industries had applied for copies of the Journal, and it was recommended that that institution be placed on the free list.

The PRESIDENT moved the adoption of the report, which, after a few words from Mr. Williams with regard to the diagrams, and an expression of pleasure by Mr. Symes at a statement that the glass cases had now arrived for the exhibition of new drugs and apparatus, was carried unanimously.

LAW AND PARLIAMENTARY.

The Secretary had reported to this Committee the receipt of a reply from the Chemists and Druggists' Trade Association, enclosing a resolution to the effect that the President, Vice-President, Mr. Barclay and the Secretary would, in compliance with the invitation of the Committee, form a deputation to accompany one from the Pharmaceutical Society to wait on the Privy Council.

Communication with the Privy Council.

The following correspondence with the Privy Council Office had been submitted to the Committee:—

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, London, W.C.
"*February* 13, 1884.

"C. L. Peel, Esq., C.B.,
"Privy Council Office, Whitehall, S.W.

"Dear Sir,—With reference to the Bill, drafted by the Council of this Society and forwarded to you in February last, to regulate the sale of poisons and amend the Pharmacy Acts, I am instructed to ask the Lord President to receive, on an early day, a deputation representing the Pharmaceutical Society and the Chemists and Druggists' Trade Association, to urge upon his Lordship the importance of introducing it into Parliament during the present session.

"Awaiting the favour of a reply,
"I am, dear Sir,
"Your obedient servant
(Signed) "ELIAS BREMRIDGE,
"*Secretary.*"

"Privy Council Office, Whitehall.
"*February* 15, 1884.

"Sir,—I am directed by the Lord President of the Council to acknowledge the receipt of your letter of the 13th inst., and I am to state, for the information of the Pharmaceutical Society, that Her Majesty's Government have decided to confine the Bill, which they propose to introduce, to the question of the sale of poisons, and not to include in that Bill any amendments of the Pharmacy Act in relation to the status or the organization of the Pharmaceutical Society.

"The Lord President also instructs me to state that if, after the Government Bill has been introduced, the Society desire to submit any observations upon it, his Lordship would be willing to receive a deputation on the subject.

"I am, Sir,
"Your obedient servant,
(Signed) "C. L. PEEL.

"The Secretary,
"Pharmaceutical Society,
"17, Bloomsbury Square, W.C."

The Committee had considered that no useful action could be taken until the terms of the Government Bill were made known, and had communicated to that effect with the Trade Association. The Committee recommended the Council to send the following letter to the Privy Council in reply:—

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, London, W.C.
"Charles L. Peel, Esq.,
"Privy Council Office, Whitehall, S.W.

"Sir,—I am directed by the Council of this Society to acknowledge the receipt of your letter of the 15th ulto., and I am to state that the Council regret to be informed that Her Majesty's Government have decided to confine the Bill, which they propose to introduce, to the question of the sale of poisons, and not to include in that Bill any amendments of the Pharmacy Acts in relation to the status or the organization of the Pharmaceutical Society.

"I have the honour to be, Sir,
"Your obedient servant,
(Signed) "ELIAS BREMRIDGE.
"*Secretary.*"

The PRESIDENT moved the adoption of the report and recommendations. The draft letter read would, he thought, sufficiently express the feeling of the Council, and was probably a sufficient notice of the receipt of the communication from the Privy Council. In the opinion of the Committee it was not desirable to move any further until the terms of the Government Bill were known. He had no reason to believe, from what information he had been able to gather, that the Government disapproved of the clauses in the Society's Bill which dealt with the organization of the Society, as it had been called. He believed that the Government did not wish at present to undertake much more than the responsibility of dealing with patent medicines, and had the idea, like most persons unacquainted with the subject, that the sale of poisons could be easily dealt with, in a clause or two, and that a short Bill could be drafted, to which there would be no opposition. Whether that expectation would be realized was another question. At present he thought it would neither be wise nor dignified for the Council to take any further action until the Bi was introduced.

Mr. SCHACHT asked for the letter from the Privy Council in which it was first suggested that the Council should draft a Bill.

The Council then went into committee to consider this subject, and a long discussion ensued.

Mr. SCHACHT said the Council had received a request in sufficiently broad terms to frame an amended Pharmacy Bill as to thoroughly justify it in expressing its regret that no amendment of the Pharmacy Act was intended by the Government, more forcibly than was set forth in the proposed letter.

The PRESIDENT pointed out that the written communications from the Privy Council had always been limited to the sale of poisons.

Mr. WOOLLEY thought there should be something added to the letter giving the Privy Council to understand plainly that in the opinion of that Council the two questions must be dealt with together.

Mr. SCHACHT also pressed the point very strongly that the Council was by the Pharmacy Acts appointed the authority to deal with questions affecting the sale of poisons, and it seemed to him that no Bill ought to be introduced in connection with this subject without the Council being consulted.

Mr. HAMPSON also thought the Council had not been very well treated by the Government, and that it could not be too clear in expressing its opinion that no Bill dealing with the sale of poisons only, and not with the other deficiencies in the Pharmacy Act, would have the support of the Council.

Similar views having been expressed by several other members of Council, it was finally decided to add the following clause to the letter to be sent to the Privy Council:—

"I am further instructed to state for the information of the Lord President that the Council of this Society fail to see how it is possible to satisfactorily amend the law in regard to the sale of poisons without at the same time dealing with the amendment of the Pharmacy Acts."

The Council then resumed, and the report and recommendations were adopted unanimously, with the addition of the above clause to the letter.

GENERAL PURPOSES.

The report of this Committee included the usual letter from the Solicitor, stating the progress of cases which had been placed in his hands.

The Committee had also considered several other cases, and in respect to some recommended that proceedings be commenced. In one case of registration the Registrar had reported that on making inquiries, the medical man who had supported the application to be placed on the Register had withdrawn his declaration, and the person in question had withdrawn his claim.

The Registrar was therefore directed to erase the name from the Register.

The report and recommendations were unanimously adopted.

REPORT OF EXAMINATIONS.

February, 1884.

ENGLAND AND WALES.

	Candidates. Examined.	Passed.	Failed.

„ (21st)	30	12	18
„ (22nd)	27	10	17
	—110	—37	—73
	117	41	76

PRELIMINARY EXAMINATION.

Two certificates received in lieu of Society's examination.

1 College of Preceptors.
1 University of London.

AMENDMENT OF THE BYE-LAWS.

Mr. BOTTLE reminded the Council that the Education Committee had been instructed to carefully examine the bye-laws, with a view to recommending any alterations which might be required in regard to educational matters; and suggested that the same Committee should have power to examine the bye-laws generally, and see if any other alterations were desirable. He thought some of the bye-laws might be modified with advantage.

Mr. WILLIAMS said this was a very wide question, and he did not see why the Committee appointed to deal with the education question only should take upon itself a function which had always been discharged by the Law and Parliamentary Committee.

Mr. BOTTLE said he did not mind which Committee undertook the duty, but if the bye-laws were to be amended at all it was just as well the work should be done thoroughly, and the whole thing brought up to date.

Mr. SCHACHT said there would be one advantage in adopting Mr. Bottle's original suggestion, viz., that the members of the Education Committee had all the details of the bye-laws at their fingers' ends. If thought desirable that Committee could submit its ideas to the Law and Parliamentary Committee, which could bring up a report to the Council upon it.

After some further conversation, Mr. Bottle's suggestion was acceded to, the names of Mr. Robbins and Mr. Williams being added to the Committee.

EVENING MEETING.

Wednesday, March 5, 1884.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

The Fifth Evening Meeting of the Session was held on Wednesday last, the chair being taken at half-past eight o'clock.

The minutes of the last meeting were read and confirmed.

As relating to a subject referred to in the minutes, permission was given for the reading of a—

NOTE UPON THE ALKALOIDAL STRENGTH OF THE SAMPLE OF EXTRACT OF NUX VOMICA, EXHIBITED AT THE EVENING MEETING, FEBRUARY 6, BY G. F. SCHACHT.

Some interest having been shown by those present during the dircussion on the paper by Messrs. Dunstan and Short, "On the Preparation of a Standard Extract of Nux Vomica," as to the exact alkaloidal strength of the extract exhibited by myself, a promise was given that the sample should be titrated and the result made known.

In fulfilment of that promise I beg to state that Messrs. Dunstan and Short have been good enough to examine the samples, and that I have also estimated the strength of the extract myself.

Mr. Dunstan reports that he finds it to contain 17·9 per cent. of mixed alkaloids.

My own examination gives me 18 per cent.

These results are practically the same.

Mr. SCHACHT, in continuation, said that the point of interest attached to the determination of the sample referred to in his note was that Messrs. Dunstan and Short, in their paper on extract of nux vomica, read at the last meeting, had given their opinion that an extract of nux vomica should be considered of standard strength when it contained 15 per cent. of the mixed alkaloids. In the discussion that followed the reading of that paper he had ventured to question whether 15 per cent. was quite the wisest percentage that could be selected. In confirmation of his doubt, he might now point out that an examination of the specimen of extract prepared by himself, then referred to, had shown that the percentage was considerably in excess of 15 per cent. The extract was of pill consistence, not syrupy, and prepared in the fashion directed by Messrs. Dunstan and Short. If samples were found on the average to contain more than 15 per cent., it would be a pity to fix 15 per cent. as the standard strength. He thought that most pharmacists would prefer an extract, properly so called, for one diluted with so much spirit and water became a little unmanageable. Such an extract would lose weight by drying spontaneously, and the dispenser would, perhaps, aid the change by gentle heat, and then it would no longer correspond to the standard. He thought that it would have been preferable if the authors of the paper had raised the standard, and that it would be better to arrive at the standard strength by mingling veritable extracts, rather than by adding diluents, such as water and alcohol, which would not give a stable preparation.

Mr. DUNSTAN said that it was not at all surprising that Mr. Schacht's extract contained more than the 15 per cent. which the paper recommended as a standard, since it was not prepared by the process directed in the paper, for as far as he knew there was no estimation made of the alkaloid in the percolate. As to the strength of extract of nux vomica, Mr. Short and he had shown in a previous paper that an average commercial extract contained about 15 per cent., rather less than more. They had examined twelve samples. If Mr. Schacht's extract had been prepared by the process the paper recommended, and which involved an actual estimation of the quantity of alkaloid contained in the strong tincture, it would have been found that the finished extract would contain 15 per cent. As it was prepared by simply exhausting nux vomica with spirit, it was not at all surprising that it contained 18 per cent. Mr. Schacht had said that 15 per cent. extracts were not of good consistence, but that depended entirely upon the nux vomica used. It would be the case if they used a nux vomica containing a low percentage of alkaloid, such as 2·2 or less than 2½ per cent., but one containing more than 2½ per cent. would give an extract which was all that could be desired pharmaceutically. Mr. Schacht used a nux vomica containing a very low percentage of alkaloid, namely, about 2·2. Of course the 15 per cent. extract prepared from that would necessarily be soft. An important objection to taking 18 per cent. as a standard was that it was rather above the strength of the ordinary extract of commerce. An alteration of 3 or 4 per cent. in a substance like extract of nux vomica would be dangerous, and further, when one used a nux vomica containing a high percentage of alkaloid, in order to obtain an 18 per cent. extract, the preparation had to be evaporated till it became too hard for convenient use.

Mr. GILES said that he thought that, in the main, Mr. Dunstan and Mr. Schacht were agreed, namely, that it was important to have a standard preparation of extract of nux vomica. As to whether the standard should be 15 per cent. or 18, it was not very important. Fifteen was a more symmetrical number, and more convenient for calculation. There were two ways of settling the question between 15 and 18 per cent. One might be to toss up for it, and, in the absence of any better mode, that would be conclusive. The other method was to refer it to a competent authority. The grievous thing was, however, that there was no competent pharmaceutical authority. If he lived for a few years longer he hoped to induce the Society to take such action as would constitute it the recognized pharmaceutical authority, and he would take an early opportunity of inviting his fellow members to support him in that movement.

Mr. SCHACHT said that he did not quite follow Mr. Dunstan in the course which led him so distinctly to the conclusion that the smaller percentage was the right one. Mr. Dunstan had rather levelled at him the fact that the specimen of nux vomica from which he (Mr. Schacht) had prepared the extract was not a good one. It had, however, given an extract with a higher percentage of alkaloidal value than the richer specimens. He candidly admitted that he was ignorant of the existence of any relations between the extractives and the alkaloids in samples of nux vomica; but from what he could gather from Mr. Dunstan it seemed that, if he had taken a sample of nux vomica which was supposed to be richer in alkaloidal value, he should have got a worse extract.

Mr. DUNSTAN said that if Mr. Schacht took the same quantity of a richer specimen as he did of his own specimen, and exhausted it in precisely the same way, the resulting extract would probably be richer than the 15 per cent. extract he was speaking of. The only way to ensure an exact result was to estimate the alkaloid.

Mr. SCHACHT said that that was so much the better for his argument, because he should then have had to reduce the extract still more to the condition of a rich syrup. All that he was complaining of was that 15 per cent. was below the strength which an extract should have. He could reduce the extract to 15 per cent. by adding spirit and water, but the extract would not be a good one pharmaceutically, and he should deprecate the addition. He followed Mr. Dunstan's directions with the single exception that he did not stop at the syrupy preparation, but made a real extract, and the result was a much richer percentage. The whole question was whether an extract was to be syrupy or of a pill consistence. From the point of view of a practical dispenser, he maintained that Mr. Dunstan's preparation was not an extract, and that if that preparation was brought to an extract it would contain more than 15 per cent.

The PRESIDENT said that it seemed to him that the author and Mr. Schacht were a little misunderstanding one another. The idea in Mr. Dunstan's mind was, while working scientifically, to come to a conclusion which he (the President) ventured to call a commercial conclusion, and one which should have the least danger to the public. In this particular instance he was disposed to agree with the advisability of keeping a moderately low percentage of alkaloid as a standard. In sanctioning a preparation of the important character of extract of nux vomica, it was necessary to take a strength which would always be obtainable from those specimens of nux vomica seeds which were the weakest in alkaloids, and which might, nevertheless, have the physical characters associated with good nux vomica seeds, so that pharmacists should have an opportunity of reducing to the standard, if need be, rather than increasing. He thought, with regard to all potent preparations, that they should be manufactured rather above the average and reduced to the standard. The practical outcome of all pharmaceutical work led him to this view. Those of the members who were onlookers in this discussion might congratulate themselves upon the fact that both sides appeared to have had the best of it.

A paper was then read entitled—

A NOTE ON LOGWOOD AS A TEST FOR METALS.

BY ARTHUR WEDDELL.

The paper is printed on p. 717, and gave rise to the following discussion:—

The PRESIDENT said that this test would not be considered by professional chemists of the same value as many others that were well known, but there were many cases in which the average pharmacist could use such a test with advantage; and they would, therefore, welcome the description of a colour test of this kind suitable for pharmaceutical purposes. He might remark that Mr. Wynter Blyth, a medical officer of health and public analyst, had published in the first number of the *Asclepiad*, a journal edited by Dr. Richardson, a paper in which cochineal was similarly used to detect lead in water. He mentioned this to show that the use of colour tests was not confined to pharmacists.

Professor ATTFIELD, by way of emphasizing what the President had said, stated that, in his opinion, the logwood test was a good one, but it was only a good negative test. In this sense it covered more ground than either sulphuretted hydrogen or sulphydrate of ammonium taken separately, whilst it covered the ground which both those reagents covered if taken consecutively. Secondly, it was a good negative test for pharmacists, because it could be readily prepared and applied. It was said that a little knowledge was a dangerous thing, but he did not think that saying held good so long as it was known that the knowledge possessed was only a little. Those who applied the logwood test should remember that it afforded only a little knowledge respecting the metals in a water. If they found that a metal was present, then, of course, they must go on to determine what metal it was.

Mr. HILLS said he regretted that the author of the paper was not present to show them the different colours obtained under the varying conditions mentioned. He (Mr. Hills) was unable just at present to confirm the statement in the first paragraph of the paper, that the colour of the logwood tincture was not affected on dilution with pure freshly distilled water; for he found that on adding the tincture to distilled water (which had been re-distilled in glass) a bluish colour was produced similar to that occurring when iron or lead was present. He might add that he had not yet tried the effect with the addition of the ammonium carbonate. Hæmatoxylin appeared to be a body of a very delicate nature, for he found it stated in Watts that "a solution of hæmatoxylin boiled in a platinum dish in an atmosphere free from ammonia acquires merely a brownish or brownish-yellow colour; but, if boiled in a test-tube, it assumes in a few minutes a purple colour, showing that the glass has been decomposed and has given up alkali to the water."

The PRESIDENT said that it was perfectly easy to talk about pure distilled water, but it was a very difficult thing to get it. The possible presence of carbonic acid and ammonia ought to be borne in mind. He was sorry that the author was not present to tell them how he standardized his test.

Thanks were voted to the author for his paper.

A paper was then read entitled—

THE CHEMICAL COMPOSITION AND PROPERTIES OF A CRYSTALLINE PRINCIPLE OBTAINED FROM JAMBOSA ROOT.

BY A. W. GERRARD, F.C.S.

The paper is printed on p. 717, and gave rise to the following discussion:—

The PRESIDENT said that he hoped that Mr. Gerrard would continue his researches and let them know more of the oleoresin.

Mr. HOLMES said that he should think that Dr. Lyons's opinion was correct, that the root was much more nearly allied to the *Piperaceæ* than to the *Myrtaceæ*; the fact of its being a sialagogue also pointed to the same conclusion.

The PRESIDENT said that it seemed hardly fair to the alkaloid for Mr. Gerrard to dismiss it as not worth further investigation, and to fix his whole love upon the oleoresin.

Professor ATTFIELD said that he, as a chemist, felt a little hurt at the dismissal which the alkaloid had received. Its further treatment from the therapeutical point of view was perhaps unnecessary, for Mr. Gerrard had taken several doses and it did not do him any harm. But the alkaloid might turn out to be an extremely interesting one from the chemical point of view. Therefore, if circumstances permitted, perhaps Mr. Gerrard would continue the investigation.

Mr. SCHACHT asked whether Mr. Gerrard had endeavoured to form any compounds such as the substance might be expected to form considering its character.

Professor BENTLEY said that he thought that it would be very important if Mr. Gerrard would investigate the oleoresin. It seemed to be amply deserving investigation. There happened to be in the paper a mention of *Spilanthes oleracea*, which was a very old remedy, and had been known as sialagogue for more than fifty years. It had been largely in use in Brazil for a very considerable period.

Mr. GERRARD, in reply, said, with reference to the alkaloid, that he had worked upon seven pounds of the root, and it yielded him less than a grain of the alkaloid. In order to obtain a sufficient quantity of the alkaloid to enable him to arrive at anything like good results, he should want a very large quantity of the drug. As to Mr. Schacht's question with respect to compounds of this substance, he could state that it did form chlorine and bromine derivatives, but the total quantity of the material which he had at his disposal was not more than 10 or 20 grains, and, hence, he was stopped by the smallness of the quantity. The oleoresin was, no doubt, the active principle, as he had stated, and it was worthy of further research. He had not had much experience with oleoresins. It was not easy to obtain bodies in a definite form from oleoresins.

The PRESIDENT said that he still felt a little grievance on account of Mr. Gerrard having disposed of the alkaloid in a summary way. He had told them that he believed that the oleoresin contained the active principle; but, it was important that the other constituents should be examined, and he (the President) confessed that the paper had not convinced him that the whole activity was in the oleoresin.

A vote of thanks to the author was passed.

The next paper read was on—

A NEW REACTION AND TEST FOR ATROPINE AND THE MYDRIATIC ALKALOIDS.

BY A. W. GERRARD, F.C.S.

The paper is printed on p. 718, and gave rise to the following discussion:—

Professor ATTFIELD said that the meeting ought not to allow that paper to pass without recording its thanks to Mr. Gerrard for the very careful way in which he had worked out the reaction. He had been particularly interested in listening to the paper, though not so much from an analytical point of view, for the reaction did not distinguish between atropine and the other alkaloids, hyoscyamine, daturine, duboisine, and so on. But it was obvious that Mr. Gerrard had obtained a reaction which showed that there were distinct differences of constitution between one group of alkaloids and another. There was a group which gave a particular reaction, and Mr. Gerrard had examined a considerable number of other alkaloids, and found that they did not give it. He (Professor Attfield) had no doubt that when he came to examine more of the alkaloids he would find some which resembled the mydriatic alkaloids and others which would give the reaction in question. This would diminish its value as a test, but he thought that it would greatly increase its value from the point of view of the chemical constitution of alkaloids.

Mr. TANNER asked whether the reaction was shown only by the uncombined alkaloids, or whether the alkaloidal salts also showed it. If so, how did Mr. Gerrard propose to deal with a solution containing alkaloidal salts?

Mr. DUNSTAN inquired whether the equation given in the paper was based upon experimental evidence, or whether it was only an inference. Had the equation been determined quantitatively?

The PRESIDENT said that he had himself made a note with regard to the equation. It was hardly fair to give a reaction of this kind on paper, without giving something more in order to satisfy them that they were not going wrong in quoting the author. With regard to the concluding paragraph of the paper, he did not agree with the author as to the value of a test of this sort. He thought that it was likely to do more mischief than good. In a test relating to alkaloids something more was wanted than an indirect process which was common to a large number of them, according to the author's own showing, and which might be common to a still larger number that he had not yet examined.

Dr. SYMES asked whether the fact that the test acted uniformly with these mydriatic alkaloids did not tend to strengthen the theory that such alkaloids were identical in composition, varying only in constitution. He thought that there was value in the paper to that extent.

Mr. GERRARD said the first question put to him was that of Mr. Tanner, who asked how he should proceed in the case of a substance which contained a salt of the alkaloid. In the case of a *post-mortem* fluid, upon getting out the alkaloidal salt in a state of solution and a state of concentration, he should simply treat it with ammonia, which would throw down the pure alkaloid. Ether would then dissolve out the atropine, and upon evaporation would yield it in a definite form. By resolution in acid and reprecipitation, it might be got in a still purer form. Then it was only necessary to test the residue with the reagent which he had mentioned, namely, mercuric chloride; and in order to make the test as delicate as possible he should suggest that the substance be placed upon a porcelain surface, and a small quantity of the reagent applied to it and heated. The mercuric oxide would then be precipitated. In using ammonia no source of contamination would be introduced, and no body which would give a red precipitate. As the ammonia was entirely dissipated by the evaporation, it might be assumed that the residue was pure atropine. This reaction was intended to apply simply to pure atropine, and not to an atropine salt. Mr. Dunstan had asked whether the equations were merely the results of inference. He might state that he had made analyses of the salts, and taken the molecular weights according to the formulæ which he had given in the paper; and he had treated them in two ways for the mercury. He had precipitated the mercury as mercuric oxide, and estimated it; and he had precipitated it as mercuric sulphide, and estimated it; and the results had been so approximate that he had come to the conclusions stated in the paper. Whether the mercury was attached to the compound in the way in which he had shown in the formulæ. it was impossible for him to say; but this seemed likely. He did not think that it was likely to be mercury of constitution. He did not imagine that the mercury took the place of hydrogen. He thought that the arguments were strongly in favour of the formulæ which he had given. The President had remarked that the reaction might be common to other alkaloids, but he believed that it was generally acknowledged that the mydriatic alkaloids were one and the same, there being only a difference of name. They were isomers, and they behaved generally in a similar way.

Mr. DUNSTAN suggested that, when the paper was published, it should contain the processes upon which Mr. Gerrard based the equations. It was extremely desirable that scientific memoirs should contain experimental results, so that future workers should know precisely how the conclusions were arrived at.*

Dr. SYMES remarked that when it was stated that the mydriatic alkaloids were identical, what was meant was that they were merely chemically identical. He should not like anyone to take a dose of atropine, for instance, as if it was a dose of hyoscyamine.

The PRESIDENT said that he confessed that he sympathized very much with Mr. Dunstan with regard to the reaction. He did not think that Mr. Gerrard was justified in giving that reaction, and he believed that the paper would be very much better without it. The subject of the paper was the question of a test. It was extremely important to determine a test, but it was not essential

* This suggestion has been adopted in some degree by Mr. Gerrard in the paper as printed on p. 718.

that they should attempt to determine what the reaction was in all cases. If an author based on a few experiments a rather important series of what might be called "chemical generalizations," it became a little difficult for succeeding authors to deal with the subject. The last paragraph of the paper, with regard to the value of the test in forensic analysis, was somewhat stronger than Mr. Gerrard could have fairly contemplated. He (the President) should think it very hard to be convicted of poisoning on the evidence afforded by the test. Mr. Gerrard had allowed the scientific use of his imagination to carry him farther than results had warranted. It was a pity to spoil a good thing by too much elaboration.

Thanks were voted for the paper.

The PRESIDENT said that at his request Professor Attfield had consented to bring to a Pharmaceutical meeting a paper he had prepared on a subject of only partial pharmaceutical interest, a paper relating to the questionable occurrence of any important amount of metal in canned or "tinned" foods.

TIN IN CANNED FOODS.

BY PROFESSOR ATTFIELD.

The paper is printed at p. 719, and gave rise to the following discussion:—

The PRESIDENT said that the paper was a very interesting one. Public analysts sometimes alarmed the public by statements based upon the finding of very small quantities of metallic substances in canned meats; and certain members of the public who did not pass preliminary examinations had often a doubt as to what the meaning of 0·0048 of a grain might be. The paper was one which showed the way in which pharmacists might be the bearers of sound technical knowledge to the public at large.

Mr. ATKINS agreed with the President that the paper might be useful on what might be called a semi-pharmaceutical aspect, by assuring the public that there was no ground for alarm. There was a widespread prejudice against tinned foods, and, as the trade in such articles was a growing one, it was desirable that the public should know that no damage would arise from it. The paper brought forward a commercial question of the very first importance.

Dr. SYMES said that Professor Attfield's remarks were also very interesting as confirming some statements made by Mr. Davis, of Liverpool, at a recent meeting of the Chemists' Association. Mr. Davis had arrived at precisely the same conclusion, that no appreciable quantity of tin was found in tinned foods.

Mr. SCHACHT said that he should like to ask whether any of the gentlemen who were accustomed to investigate articles of food for the detection of tin had ever had samples of brown sugar submitted to them for that purpose. A sample of sugar was submitted to him some time ago under the suspicion that a tin compound had been used to produce its beautiful colour; and in a quantity of two pounds he succeeded in getting the faintest conceivable evidence of something which looked very much like tin.

Mr. HOLMES said that a source of danger not mentioned in the paper, in connection with tinned foods, was imperfect soldering, and the consequent passage of air into the can. Under such circumstances microscopic fungi, such as *Penicillium glaucum*, which was known to be poisonous when grown on bread, developed itself. An instance of poisoning by means of this fungus was related in the *Medical Journal* of the previous week. When tinned fruit had been opened and left in the tin for a couple of days, the juice acquired a distinct metallic taste. The same result would be observed in tinned milk which had been opened and left to dry about the tin. He was not surprised that people were afraid of tinned food when they perceived such a taste.

Professor ATTFIELD said, in answer to Dr. Symes, that he had only to remind him that he (Professor Attfield) was not the only one who had drawn attention to this matter, and he hoped he should not be the last, for before such a prejudice as existed in the public mind could be uprooted it would be necessary that many men should make statements of the same kind as those contained in his paper. As to the examination of sugar, some twenty odd years ago, he occasionally found traces of lead, but not of tin. He believed that at that time certain refiners were in the habit of using lead, and it was just possible that a faint trace was left in the sugar. There were complaints on the subject and the evil soon cured itself.

The PRESIDENT said that he believed Dr. Scoffern's process was worked at that time, and afterwards abandoned.

Professor ATTFIELD said that that was the case. With regard to Mr. Holmes's remarks, of course it was well known that if air got into a tin of food it was only a question of time for the food to get damaged and afterwards to become putrid. In the early days of canning manufacturers had difficulties to contend with on that score. He had known them to put the tins of food into a warm room, in order that the putrefaction might take place in their own factories if it was likely to take place at all. As to residues of tinned foods which were left in open vessels, there was no doubt that they might take up portions of tin, iron, or other metal, for if a dirty can was left in contact with the air, both the tin and the iron would become oxidized. If persons were unwise enough to let the food remain long in an opened tin they almost deserved to be punished by the metallic flavour which might possibly be communicated to the residual food.

The PRESIDENT said that it was of the utmost importance when a tin was opened that the whole of the food be at once turned out. He had never yet observed any serious effects when that was done. The palate was in some cases better than any chemical test, and it could detect a difference between fresh lobster and the very best tinned lobster. This difference was often erroneously attributed to metallic contamination. Considering the enormous importance of the articles of food preserved in tins, the paper which had been read might have practical uses in many ways.

Mr. HOLMES called attention to various Museum specimens on the table. There were some samples of the kola nut in a fresh state. It had been said that the red and the white seeds occurred in the same pod, and from the present specimens that seemed to be very likely. He had put on the table some of the bitter kola nuts. In some parts of Africa these were turned to the same uses as the true kola nuts. One curious feature in connection with the bitter kola seed was that although it was a dicotyledonous plant, it did not possess two cotyledons. The specimen of cymene was interesting as having been prepared by a student in the School. The specimen of squill was presented by Mr. Roberts, an old student. It seemed to be of the red variety which was mentioned in the 'Pharmacographia.'

The PRESIDENT announced that the next evening meeting, the last one of the session, would take place on Wednesday, April 2.

Provincial Transactions.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

The third ordinary meeting was held at the Owens College (by permission of the Council) on Tuesday evening, February 26, Mr. W. Wilkinson in the chair.

The minutes of the last meeting having been read and confirmed, the Chairman called on Mr. W. Kirkby to read his paper on "Disinfectants."

Disinfectants.

BY WILLIAM KIRKBY.

The author opened his paper by a few remarks on the progress of knowledge in connection with diseases since the enunciation of the "germ theory." The work of several scientists bearing on the subject of disinfectants was then passed in review, the researches of Le Bon being first noticed. Special attention was called to the important conclusion he arrived at, viz., that the disinfectant is not the only thing to be considered in the destroying of micro-organisms, as the efficacy of it depends a great deal on what stage of putrefaction the substance is in. The result of his experiments showing that there is no connection between the power of preventing putrefaction and that of arresting it, and also that the virulent power of a putrefying substance and the toxic nature of the volatile compounds given off by it are not necessarily in any relation to one another was briefly considered, together with a short sketch of his experiments. Passing then to Koch's work, the principal points noticed were that he considers an efficient disinfectant to be one that will destroy organisms in twenty-four hours, and that he found carbolic acid to have little or no effect on the spores of *Bacillus anthracis*, but when putrefaction had set in its action on the organisms was very marked.

Having reference to these experiments, it must be evident that it is too much to expect any substance to act in the same manner and with the same energy on every kind of organism. Koch used only aqueous solutions of carbolic acid in his investigation, as solutions in oil and alcohol were found to be without effect. The same investigator has reported that sulphurous acid gas has no action unless the articles to be disinfected are first moistened, and even then the germs are not all destroyed. He found that, besides chlorine, bromine and iodine, the only reliable disinfectants are corrosive sublimate, osmic acid and potassium permanganate. Wolffhugel and Knorre's corroboration of Koch's results and their reasons for the inefficacy of oily solutions of carbolic acid next claimed attention. Boillat's argument, that although a substance may not destroy organisms, it is quite sufficient for surgical purposes if it arrests the development of the spores, being noticed the author passed on to the researches of Arloing, Cornevin and Thomas. They give as the outcome of their work a list of useful and useless substances in the case of symptomatic *Anthrax*. The most powerful they consider to be carbolic acid, salicylic acid, boric acid, corrosive sublimate and bromine gas. They state that quicklime does not destroy these organisms.

A summary was placed before the meeting of the knowledge which had been acquired by a consideration of the valuable results communicated at various times by these scientists. Carbolic acid may be set down as a good preventive of the development of bacteria; but, except in a few cases, has only feeble action on the living organisms. It was recommended that oily solutions of this disinfectant should be abandoned. Potassium permanganate is more effectual in destroying the living bacteria than in arresting development. Salicylic acid appears to be of considerable service. The other articles mentioned in the paper were just glanced at. The author concluded by saying many articles had been shown to have no just claim to the name of disinfectant; others are only of limited utility, and that no one article, except it be powerful poison, can be used for every kind of putrefaction.

After the reading of the paper, a discussion ensued, in which the Chairman, Messrs. Hermann Woolley, Lane and Elborne took part.

Mr. Kirkby having replied,

The Chairman called upon Mr. Elborne to read his paper on "Exotic Henbane."

Exotic Henbane.

BY WILLIAM ELBORNE,

Assistant Lecturer in Materia Medica and Pharmacy, and Curator of the Materia Medica Museum, Owens College.

About a month ago my attention was drawn to the fraudulent nature of some exotic henbane which was being offered in the market, receiving a sample of the same for examination with the accompanying letter:—

"Bodicote,

"*Jan.* 23, 1884.

"My dear Sir,—There are doubtless many evils in the world which can never be eradicated, but there are yet many of a fearful character which certainly may be annihilated by the advance of science. Is it not astounding that with the great advance in chemistry and pharmacy and the growing caution in the administration of medicine that an article such as I herewith enclose you should find customers in this country to the extent of some tons? It is sold as henbane leaves, on the preparations of which may depend the lives of hundreds of human beings. A foreign house has to-day had the impudence to offer me half a ton at 40*s.* per cwt. I think it right that such facts as these should be made known to such institutions as those of which you are a member, for I cannot either in appearance or flavour of the drug enclosed detect any relation to the plant *Hyoscyamus.*

"I am,

"Yours faithfully,

"To Mr. W. Elborne." "RUFUS USHER.'

The specimen consisted of dry shrivelled up leaves and stalks, with a peculiar odour altogether unlike that of henbane, and upon a careful examination I found it consisted entirely of the leaves of *Datura Stramonium.*

Having discovered the nature of the substitution, it occurred to me to ascertain as far as possible the purity of all the varieties of henbane in commerce, with the view of ascertaining to what extent this substitution was being practised.

I therefore obtained supplies from the leading wholesale houses in London and Manchester, and received quantities of the following (arranged in the order of their value):—

Biennial henbane, second year's growth.*
Biennial henbane, first year's growth.
British annual henbane
German henbane.
Exotic henbane.

Being under the impression some confusion exists or has existed, in relation to the subject of henbane, I might remark before giving the result of my examination that "biennial" and "annual" henbanes are yielded by distinct plants, viz., *Hyoscyamus niger*, var. *biennis*, and *Hyoscyamus niger*, var. *annua*.

The former (the biennial) produces in the first year only a rosette of stalked radical leaves 9–12 inches in length; in the second year throws up a flowering stem 2 or 3 feet in height; and then as the fruit matures the whole plant dies: whereas the annual variety produces its stem, flowers and fruit in the same year and then dies root and stock. It is the second year's dried leaves and flowering tops of the biennial plant which are official in the British Pharmacopœia for the preparation of the tincture, and when obtainable none other should be used.

Having received authentic samples of the latter from Mr. Usher (who probably is the largest grower of henbane in this country), that directed to be used in the Pharmacopœia in the dried state might be described as occurring in nodules (something like Brussels' sprouts) consisting of hairy leaves and purple veined flowers closely matted together, free from stems and stalks. The first year's leaves of the above (erroneously called "annual henbane") may readily be distinguished by their possessing long radical petioles or stalks, and by the total absence of flowers; whereas the

* The only kind recognized in 'Brit. Pharm.'

real British annual henbane in the dried state is found in the form of stalked leaves attached to a stem bearing light yellow flowers less streaked with purple, and the whole plant of a lighter colour and less hairy.

The following is the result of my examination of the numerous samples received. The whole of the English biennial, both second and first years' leaves, were of the best quality, and entirely free from any adulteration or substitution, while the samples received as "German" and "exotic" consisted of the "*annual*" mixed largely with stramonium leaves. The above remarks will tend to show that "exotic henbane" as at present found in commerce is a most worthless article deserving no mention in English pharmacy.

It is, however, satisfactory to learn that the demand for "exotic" is very trifling and that the English biennial maintains its high character as being a pure drug.

After the reading of the paper, a discussion ensued, in which the Chairman, Messrs. Hermann Woolley and Lane took part.

Mr. Elborne having replied,

The Chairman proposed hearty votes of thanks to Messrs. Kirkby and Elborne for their papers, which were seconded and carried with acclamation.

The Chairman then, speaking at some length, took the opportunity of impressing upon the young men present the great advantages which they might derive from cultivating their mental faculties and powers of observation and investigation by writing papers on subjects of interest to pharmacists, and communicating their results to Associations, where much additional knowledge might be learnt from the discussions arising therefrom.

The Chairman having announced the next meeting, the meeting then terminated.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The ordinary monthly meeting was held in the Society's rooms, on Wednesday evening, February 20, Mr. Preston, the President, in the chair..

The Secretary announced the following donation:—The *Pharmaceutical Journal*, from the Pharmaceutical Society of Great Britain.

The President then called upon Mr. H. S. Smith to read his paper on "Volumetric Estimation." Mr. Smith commenced by pointing out the desirability that every chemist and druggist should be able to assure himself, by personal experiment, as to the preparations kept by him being of proper strength, and that for this purpose he should know how to make a volumetric estimation. He recommended masters, therefore, to encourge the study of volumetric analysis by their assistants and apprentices. He then proceeded to describe the principles upon which volumetric analysis is based and showed that it was an application of Dalton's atomic theory. Taking, as an example, lime water, he explained, in detail, the official method of testing it and the facts upon which it is based. Referring, finally, to the subject of indicators, Mr. Smith spoke favourably of the use of phenolphthalein for this purpose.

Mr. Marshall, in proposing a vote of thanks to Mr. Smith for his valuable paper, spoke of the advantages to be derived from a knowledge of such mode of analysis and how essential it was that every chemist and assistant should be thoroughly acquainted with it, both for his own sake and that of the public. He said that during the last few weeks he had examined several samples of lime water, obtained from different shops in the town, and that quite one half of them did not come up to the B.P. standard.

Mr. Fromer seconded the vote of thanks, and, others supporting, it was carried unanimously.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A lecture was given on Wednesday evening, February 27, at the room of the above Association, by Mr. Pickering, the subject being "Electro-plating."

The lecturer commenced by describing the apparatus and chemicals required in this very useful process, giving the rules to be observed during the operation, explaining fully the strength of solutions employed, and impressing upon his hearers the utmost need of perfect cleanliness of the article to be plated. The lecturer then showed to his audience the practical work; first by plating an article with copper, after which he deposited upon it a coat of silver. Besides this, he coated a piece of metal with gold. To all of this, as well as the theoretical part, great attention was paid by the members.

A vote of thanks, proposed by the Chairman, Mr. J. J. Edwards, to the lecturer, concluded the meeting.

Proceedings of Scientific Societies.

ROYAL INSTITUTION.

Theory of Magnetism.

On Friday evening, the 29th ult., Professor Hughes delivered a lecture at the Royal Institution, in which he propounded a theory of magnetism, supporting and illustrating it by a number of observations made by him in recent researches that have not yet been published. He commenced by reminding his audience that Coulomb had conceived the idea that when a molecule of matter containing equal quantities of the two magnetic fluids became magnetized, the fluids were definitively divided, and collected at the opposite sides of the molecule. According to Ampère the magnetic fluids revolve round the exterior of the molecule, thus making each molecule a perfect electro-magnet. Professor Hughes, however, considers that all matter, even the ether by which the molecules are surrounded, is magnetic, and that polarity occurs by rotation. The lecturer did not put forward this latter theory as being original, but merely stated that he had taken it as a basis for his researches. In the theories of Coulomb and Ampère it is necessary to suppose the existence of coercive force, but in his own no such supposition is required; indeed, he is of an opinion that what has been called coercive force represents really only the comparative hardness or softness of the iron or other material. Professor Hughes remarked that he had been indebted to the introduction of the induction balance for many of the results which he had obtained, and explained the principal points of a very sensitive needle which he used for many illustrations of his lecture. In demonstrating the difference between the magnetic properties of steel and soft iron, the lecturer magnetized a bar of each, and showed that whilst the steel bar retained magnetism when struck, the soft-iron bar lost all traces of it when dealt a few sharp blows. Not only is this the case, but if the blows be continued, the soft-iron bar becomes magnetized by the earth's polarity. The same results are obtained by application of heat or electricity, or if the bar be allowed to fall some distance. As this latter experiment would necessitate a drop of several feet, the lecturer replaced the bar by a bottle of loose iron filings, which arranged themselves according to the earth's magnetism when dropped for a few inches. The steel bar, though subjected to the same influences, still retained its original magnetism. This difference Professor Hughes considered due to the loose state in which the molecules are held in soft-iron. In proof of this supposition, he showed that a sharp twist of a soft-iron bar produced the same effect as the blows, but that if it were compressed at both ends, so as to keep it in a rigid state, the same results were obtained as with the steel bar. Another proposition put forward by the lecturer was to the effect that the polarity of the magnet was due to the direction of its stratification, and he showed that when the stratification was reversed the poles were also changed. An account was also given of some experiments upon the atmosphere, which tended to show that in some respects it possesses a magnetic action like that of iron, and this fact Professor Hughes considered to support his theory that there is no magnetic fluid as distinct from the molecule, but that magnetism is an inherent quality in every atom of matter. An interesting experiment was also made, showing that sound is produced by a bar of iron being magnetized, though full explanations could not be given of this and other points owing to the limited time.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, February 28, Mr. H. G. Greenish, Vice-President, in the chair.

Mr. F. McDiarmid read a paper on—

Some Silicon Compounds.

The object of the writer was to trace out the great resemblance which silicon bears to carbon. In the first place it was shown that, like carbon, silicon exists in three allotropic conditions: amorphous, graphitic and crystalline, specimens of two of which were exhibited, and their modes of isolation explained. The chief compound, viz., silica SiO_2 bears a great similarity to CO_2, forming salts with metallic oxides, which are decomposed by acids. The preparation and properties of the following compounds were described, and attention was directed to their analogy to the compounds of carbon:—

Silicon compounds.	Carbon compounds.
SiH_4 silicon hydride, siliciuretted hydrogen or silicomethane.	CH_4 carburetted hydrogen or methane.
$SiCl_4$ silicon tetrachloride.	CCl_4 carbon tetrachloride.
$SiHCl_3$ silicon chloroform, or trichlor-silico-methane.	$CHCl_3$ chloroform or trichloromethane.
$SiHI_3$ silico-iodoform.	CHI_3 iodoform.
SiI_4 silicon tetriodide.	
Si_2I_6 silicon teriodide, from which may be obtained a compound.	
$Si_2O_4H_2$ silico-oxalic acid.	$C_2O_4H_2$ oxalic acid.
SiS_2 silicon disulphide.	CS_2 carbon disulphide.
$(SiOH)_2O$ silico-formanhydride.	$(COH)_2O$ formic anhydride (unknown).

There is a large class of bodies, called silicic ethers, which are produced by the action of alcohols on silicic chloride ($SiCl_4$) and are silicates of alcohol-radicals, *e.g.*:—

$(C_2H_5)_4SiO_4$ ethylic ortho-silicate.	$(C_2H_5)_4CO_4$ ethylic ortho-carbonate.

From these, by various decompositions, may be obtained acids in which the carbon of the carboxyl (COOH) group is replaced by silicon:—

CH_3SiOOH silico-acetic acid.	CH_3COOH acetic acid.
$HSiOOH$ silico-formic acid.	$HCOOH$ formic acid.
C_2H_5SiOOH silico-propionic acid.	C_2H_5COOH propionic acid.

In the same way the carbon in some of the hydrocarbons may be replaced by silicon:—

$Si(CH_3)_4$ silicic methide or silico-pentane.	$C(CH_3)_4$ tetramethyl-methane or pentane.
$Si(C_2H_5)_4$ silicic ethide or silico-nonane.	$C(C_2H_5)_4$ nonane.

The processes for the preparation of most of the above compounds were given, and specimens of the principal compounds shown.

The paper was followed by a discussion, in which the Chairman, Secretary and Mr. Dymond took part.

A Report was then read by the Reporter on Botany, Mr. E. Baily, on "The Continuity of Protoplasm in the Vegetable Cell," in which he brought under the notice of the Association the recent discoveries by Hillhouse and Gardner of filaments of protoplasm connecting the contents of certain cells with each other, which threw much light on the problem of how sensation was conveyed from one part to another in certain plants. He also drew attention to the closer resemblance between plants and animals which was thus indicated, the filaments of protoplasm in plants bearing a resemblance to the nervous system in animals.

The Report gave rise to a discussion, in which the Chairman, Secretary, Messrs. Dymond, Ranken, Short and Thompson joined.

Mr. Thompson then gave the second part of his Report on the "Separation of Chlorides, Bromides and Iodides."

The Report was discussed by the Chairman, Secretary, Messrs. Baily and Eastes.

The meeting then adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the Chemists' Assistants' Association, held on February 27, Mr. Parkinson, President, in the chair, a paper on "The Coal Tar Derivatives used in Pharmacy," was read by Mr. Joseph F. Burnett. The paper opened with a brief description and history of the distillation of coal for gas and tar, and then turned to the constituents and destructive distillation of coal tar, referring particularly to those derivatives which were found in medical and pharmaceutical use. Benzol and its preparations and homologues came first, including nitro-benzol, aniline and the dyes (one of which, rosaniline, was occasionally administered medicinally), toluol, cresol and xylol. Next carbolic acid was noticed, together with those bodies formed from it, such as picric acid, trichlorphenol, the sulphocarbolates, salicylic acid, etc. Salicylic acid was considered with a view to drawing attention to the fact that the artificial was not exactly identical with the natural. Naphthalene and naphthol next claimed attention, and the graphic formula of naphthalene was exhibited with a view to explaining the difference between alpha and beta naphthols, etc. Anthracene and its commercial value were referred to, and a summary of the coal tar distillates in the order of their fractions was given. The paper was brought to a close by an allusion to the bases of coal tar, viz., pyridine and chinoline, etc. The chinoline derivatives, notably kairine, were considered.

About three dozen specimens of the more important products were on the table.

A discussion followed, in which the President, Messrs. Alcock, Cracknell, Flintan and Worley took part.

Parliamentary and Law Proceedings.

"Milk of Sulphur"—Prosecution under the Sale of Food and Drugs Act.

At the Altrincham Petty Sessions on March 3, 1884, Mr. Henry Edward Goodwin, chemist and druggist, of Sale, was charged before Mr. John Allen (Chairman), and Messrs. Edward Collins, H. T. Gaddum, R. P. Gill, and Jesse Haworth, with having sold lac sulphuris as milk of sulphur (*sic*).

The prosecution was conducted by Mr. Harris, magistrates' clerk, on behalf of the authorities, and Mr. Goodwin was defended by Mr. Henry Glaisyer, instructed by the Secretary to the Chemists and Druggists' Trade Association of Great Britain.

Mr. Harris said Mr. Goodwin was charged with having sold, on February 6 last, to the prejudice of one Nathan

Large, the purchaser, a certain drug, to wit "milk of sulphur," which was adulterated with 50 per cent. of sulphate of lime, and was not of the nature, substance and quality demanded by the purchaser, contrary to section 6 of the Food and Drugs Act, 1875.

Mr. Nathan Large deposed that he was an Inspector of Police stationed at Sale. That on February 6 last he went to the defendant's shop and purchased a quarter of a pound of milk of sulphur, for which he paid 5*d*. After he had paid for it, and it had been handed to him, he told the defendant he had purchased it for analysis by the county analyst, and offered to divide the sample into three parts, which offer the defendant declined. He then sealed it up in defendant's presence and numbered the packet 169. After he had told the defendant that he had purchased the article for analysis the defendant said it was not precipitated sulphur, but milk of sulphur containing lime. If the defendant had made that statement before the purchase had been completed he would not have brought it away, because he would have known that he was being supplied with a mixed preparation. He afterwards handed the sample to Superintendent Leighton. Cross-examined: He asked the defendant for milk of sulphur and not for precipitated sulphur. He was served by Mr. Goodwin's assistant, but Mr. Goodwin was himself present at the time the purchase was made. The sample of sulphur purchased was labelled when supplied to him. There was a label put on, but he did not know what became of it. He did not see it afterwards. He did not tear it off or see anyone else tear it off. He did not know at all what became of the label; the packet was labelled when it was handed to him, but he did not see the label afterwards. He did not throw the label on the floor of the shop, or see anyone else throw it there. He asked for milk of sulphur and the drug was supplied to him as milk of sulphur. Before he took the packet away the defendant said it did not contain precipitated sulphur, but milk of sulphur containing lime.

Francis Hinley gave confirmatory evidence.

Inspector Leighton deposed to having received from Large a sample marked 169, which he conveyed on the same day to Mr. Carter Bell, the analyst for the county, whose certificate on the analysis he held in his hand.

Mr. Glaisyer said he had given notice on behalf of the defendant, that he should require the presence of the analyst, and that as Mr. Bell was present it would, he thought, be better that the analyst should put in his own certificate.

Mr. Joseph Carter Bell deposed that he was public analyst for the county of Chester. He received a sample of sulphur from Inspector Leighton on February 6 last, numbered 169. That on analysis he found the said sample to contain 50 per cent. of sulphate of lime. Milk of sulphur should be pure. Cross-examined: Milk of sulphur should be pure, and he should say it should contain no lime. He knew an article called sulphur præcipitatum, B.P. He believed that article was not called milk of sulphur. He believed that preparation was not called milk of sulphur in any pharmacopœia. That preparation did not contain any lime. Neither lac sulphuris nor milk of sulphur was mentioned in any part of the British Pharmacopœia. The term lac sulphuris and milk of sulphur were, however, both mentioned in old pharmacopœias of more than one hundred years ago, and the preparation ordered in those old pharmacopœias did contain sulphate of lime. Consequently there were two preparations known, the one as lac sulphuris, or milk of sulphur, containing lime, and the other as sulphur præcipitatum, or precipitated sulphur, without lime. These were two distinct preparations, the one containing lime was mentioned in a pharmacopœia published so long ago as 1721. There certainly were two articles, and the one made according to the formula given in this 1721 Pharmacopœia and known as milk of sulphur, or lac sulphuris, would necessarily contain sulphate of lime, and the other made according to the recent Pharmacopœia and known as sulphur præcipitatum, or præcipitated sulphur, would not contain lime. He recollected the case of Mr. Marshall, of Runcorn, who was prosecuted in 1876 for selling a similar article to this supplied by the defendant in the case under the consideration of the Bench. The quantity of sulphate of lime contained in the article supplied by Mr. Marshall was about the same or rather greater than that contained in the sample supplied by the defendant, Mr. Goodwin. The Bench at Runcorn convicted Mr. Marshall, he knew, and the case was appealed to the Knutsford Quarter Sessions.

Mr. Glaisyer: At Knutsford, in April, 1877, the case having been very freely gone into, did the Chairman, Mr. Horatio Lloyd, in giving judgment, make use of these words?—"We have been considering this matter since we left the Court, and I am speaking now for all the magistrates who have heard the case. We think although the absence of this substance (milk of sulphur) from the Pharmacopœia would justify the county analyst in taking these proceedings, we cannot for one moment doubt, after the evidence of Mr. Pemberton and others, that in the trade and in the profession there are two distinct things known by the names respectively of milk of sulphur and precipitated sulphur, and that they are supplied to the trade and to the public by those names as two distinct things. We cannot doubt that after the evidence of Mr. Pemberton, who has been prescribing this thing under the very name it was asked for on this occasion, this being a penal action we cannot say otherwise than it has not been made out, and that the appellant committed no offence within the meaning of this Act."

Witness: Yes, but there was no evidence at the hearing of that appeal to support mine; it was a one-sided decision.

Mr. Glaisyer: At all events, one-sided or not, it was the decision of the Court. Now, Mr. Bell, do you recognize the *Lancet* as a medical authority?

Witness: Yes.

Mr. Glaisyer: Then in the *Lancet* of January 6, 1877, appeared this article, "Milk of Sulphur.—When shall we have the last of the wrangles about milk of sulphur? Everyone knows that the article commonly sold as milk of sulphur always contains and must from the way in which it is prepared contain sulphate of lime. It appears to be commonly preferred to the pure precipitated sulphur, and we confess we do not see any reason why it should not be sold if not misrepresented. Milk of sulphur does not mean pure sulphur, but a particular preparation, and we think the Runcorn magistrates were in error in deciding that a purchaser who went to a certain shop for milk of sulphur did not get what he asked for. If he wanted pure sulphur he asked for the wrong article, which was not the fault of the tradesman. The man who wants bread and asks for cake cannot reasonably abuse his baker. Notice of appeal has been given in the Runcorn case, and we trust that a final decision in this not very important question will ere long be obtained." In continuation, he said it had been admitted by the witness that Mr. Marshall, of Runcorn, was convicted by the magistrates there for selling as milk of sulphur an article similar to that supplied by the defendant in this case, and that the conviction was quashed by the decision of the Quarter Sessions Bench at Knutsford. If you think it necessary I am prepared to go further into the matter; but if the case is to go to Knutsford again, I think the responsibility of taking it there should rest with the prosecution, and that the decision of the Bench should be in my favour.

The magistrates conferred.

The Chairman: Is milk of sulphur ever prescribed by medical men at the present time, Mr. Bell?

Mr. Bell: No, sir.

Mr. Glaisyer: I most emphatically contradict that statement; I know of my own knowledge that it is still prescribed by medical men eminent in their profession.

The Chairman: The Bench have decided to take Mr.

Horatio Lloyd's view of the case and dismiss the summons.

Mr. Bell, addressing Mr. Glaisyer: My costs, if you please.

Mr. Glaisyer: No, Mr. Bell, we shall most certainly not pay you any costs. The words of the statute are quite clear upon that point by section 21. "At the hearing of the information in such proceeding the production of the certificate of the analyst shall be sufficient evidence of the facts therein stated, unless the defendant shall require that the analyst shall be called as witness." I, on behalf of the defendant, required that you should be called as a witness for the prosecution, and their case was incomplete without your being so called as their witness.

Mr. Harris: That is so; the other side required us to call the analyst as a witness, and we could not complete the case without doing so.

The Supposed Poisoning Case in Sheffield.

The adjourned inquiry into the circumstances attending the death, at Park, Sheffield, of Fred Castle, six weeks old, was continued, on Monday, at the New Inn, South Street, Park, before Mr. Wightman.

Mr. Preston, President of the Sheffield Pharmaceutical Society, was present to watch the proceedings.

The inquest had been twice adjourned, once to enable a *post-mortem* examination to be made by Mr. A. Hallam, and then, in order that the contents of a bottle might be analysed. This bottle was obtained from the shop of Mr. Wilcock, grocer, South Street, Park. Mr. Wilcock had supplied from it a mixture, some of which had been given to the deceased; and the supposition was that this mixture had caused the child's death.

Mr. A. H. Allen, borough analyst, said he had received a bottle from Police Constable Thornton, and had analysed its contents. He found it contained meconic acid and morphia, which were the two characteristic principles of opium, and which proved its presence. He had also examined the four or five drops of the liquid which remained in the smaller bottle, and found that the smell and colouring were identical with the contents of the larger bottle. In his opinion it was the same mixture, but he could not swear that it was, because of the exceedingly small quantity he had received for analysis.

In answer to the Coroner, Mr. Hallam said that he still adhered to his statement made at the last inquiry, viz., that he could not swear that the child died from any narcotic at all. The actual cause of death was congestion of the brain and lungs, caused by opium.

The Coroner said that as Mr. Hallam could not swear that the child had died directly from opium, the jury could only say that it had died from congestion of the brain and lungs. He thought that the grocer was to blame, inasmuch as, though he sold the mixture, he never took the trouble to ascertain its ingredients.

The Jury returned a verdict in accordance with the medical testimony.

Death from an Overdose of Chlorodyne.

The death is reported at Kendal of Mr. Robert Anderson. It appears that for some time past he has complained of being unable to sleep at nights, for which he has been in the habit of taking small doses of chlorodyne. On Wednesday night he retired to rest at about half-past ten o'clock, and on being called by his landlady about seven o'clock on Thursday morning, he returned no reply. The room was thereupon entered, and deceased was found to be in a deep state of unconsciousness. Dr. Sturridge was at once sent for, who upon his arrival pronounced him to be suffering from the effects of an overdose of opium. Every effort was made to bring him round during the day, Dr. Iliffe being also in attendance, but notwithstanding all they could do, the unfortunate young gentleman died shortly before four o'clock in the afternoon, never having shown any symptom of returning consciousness. Beneath his pillow were two bottles that had contained chlorodyne, both of them being quite empty.

The Pharmaceutical Society.

Sir,—One sometimes meets with gentlemen who seriously contend that the universal spread of education is very far from being an unmixed blessing. It is about as satisfactory to argue with these individuals as it is to contest the opinions of those who deny the right of the Pharmaceutical Society to the slightest share of our gratitude. For my part I contend that if the Society could show no other *raison d'etre* than the Benevolent Fund, it could very reasonably demand the support of every right minded person. A society which gives away over £2000 a year for the relief, not only of the members actually connected with it, when in distress, but also to the members of the trade outside its pale, surely must merit something more than consignment to eternal perdition. But let us see how this Benevolent Fund has been brought to its present state. Has it been raised by the individual subscribers sitting still and trusting to Providence and the Council to do everything? Is it not rather that every individual subscriber has done something, be it much or little, towards the sum total. Had the whole trade acted in a similar manner, three or four times the amount might have been easily raised. Therefore, when Mr. Wilkinson's noisy friends next shriek out, "What has the Society done?" let him first of all ask them, "What have you done, individually? Have you done your best to achieve the Utopia for which you are seemingly so anxious?" Let Mr. Wilkinson point his friend to the Benevolent Fund as a result of individual effort, and tell him that to accomplish this has needed something more than a mere reliance upon the Council. Unless the trade are resolved to alter the present state of affairs, the Council is as powerless as a piston rod without steam; but if the trade only say that this sort of thing shall stop, then fifty Councils could not say nay. Mr. Wilkinson thinks one of the principal reasons why the Council exists is that it may see that pharmacists are not summoned on juries. Now to carry out his own ideas of representation, as opposed to individual effort, let him make a pilgrimage (in his official capacity as representing this much abused Council) and inspect the jury lists at the proper time to see whether any of us are "on" who are entitled to be "off," for whilst we have a local secretary, why should we trouble to examine them ourselves?

I should decidedly like to see the Council adopt a more vigorous policy with respect to the members who do so much to bring disgrace upon our trade; but so long as we make local secretaries and members of local committees of the men who think that their only aim in life is to rob their poorer brethren by sending out an army of half starved men at a starvation rate of wages, to palm off upon ignorant shopkeepers, teething powders containing antimony, cordials, preservatives, etc., containing laudanum, I am afraid it is too much to expect the Council to move. Let us ostracize these men, though they have the wealth of Crœsus or have half the alphabet after their names; let us show the public that though these men are with us they are not of us. Having done this we can then go to the Council and demand a clause or a bye-law expelling these parasites from the Society and the trade. In conclusion, I would say let individual effort be the guiding star in this important question, it will accomplish much in a comparatively short space of time, whilst years or centuries of exclamations and angry taunts will do nothing or even worse than nothing, and let us all remember that though—

"'Tis not in mortals to command success,

Yet

"We can do more—deserve it."

131, *Embden Street, Manchester.* J. HART.

Sir,—I have read Mr. Wilkinson's letters and it grieves me to see such a wealth of child-like sympathy running to waste when it is so much needed here. We have a large assortment of "poor beggars" languishing in our neighbourhood, and, what may surprise Mr. Wilkinson, we do not love them, and in the hardness of our hearts have a quaint idea of letting them have a healthy time of it, and so induce them to consider the beauties of an emigration scheme. A dozen of them (we have plenty more) keep shops undistinguishable from those of registered men, and a few do a small wholesale as well, supplying Godfrey's cordial and other child destroyers to hucksters and "twopenny-halfpenny shopkeepers." Of this dozen two only, as far as I can learn, ever served an apprenticeship, and as a reward for their superior merit, have post offices attached to their businesses, and up to date are doing very nicely. The rest are a "scratch" pack of fried fish sellers, druggists, porters and mill hands.

Mr. Wilkinson can pour out his pity on this little flock of black sheep, for we have very little of the article in stock here, and I fancy these good people will soon need it.

None of these pharmaceutical poachers come up to Mr. Wilkinson's ideal "poor beggars." The two post masters come nearest, but are not all that he would require in the martyr way, for one openly defies the law on the plea that he was in business before the passing of the Act (he was nearly of the mature age of fifteen at the time), and the other, after fulfilling his apprenticeship, hung about for a bit and then went to one of the London coaches to be crammed, but was referred back to his studies as not having sufficient elementary knowledge, and then, although he knew that several of his *confrères* had been recently warned by the Registrar, he opened a shop. Is it pity these men deserve?

And now for another type. This man, who has bragged in my presence of the large doses of powerful drugs he has given to patients, where doctors hesitated, has recently left his employment to attend to his drug business—it pays so well. I am sorry I cannot say what his late employment was; it was something in the machinery way, I believe, for he was always very grimy with soot and ashes; probably he was a stoker or something of that sort. But it does not matter much, for now he is talking learnedly to ignorant dupes of the virtues of tincty-oppy-hi ("as we chemists call it"), such being his favourite pronunciation of tinct. opii.

Mr. Wilkinson, in his second epistle, seems to think we hould be surprised if we knew the number of letters he had received approving of his sentiments. I for one should not be at all astonished, if I only was certain that all our "poor beggars" could read and write—which is doubtful. Still, I know as a fact that the papa of one of the more juvenile offenders thinks it very clever indeed, and has said so, which is very comforting.

I for my own part dislike the stores about as much as a certain historical character is reported to dislike holy water; but then the *employés* of such institutions are educated people, and such companies furnish foeman worthy of the steel of the Pharmaceutical Society, so that it ought not to be necessary for the Council to waste its strength on individuals when companies are to be fought. But, unfortunately, the House of Lords have tied their hands to a great extent. In each town the chemists ought to help themselves and ventilate a few of the most notorious and easily reached offenders in the police court. The police would finish the work. Such is the opinion of

NUX VOMICA.

Sir,—I do not know that I need say much in reply to Mr. Newsam or your other correspondent, who has not the courage to justify his criticism by appending his name. I think I am perhaps quite as loyal to the Society and as ready to lend a helping hand to further its real interests as anyone else; but I am not one of those who think that loyalty to any institution necessitates the approval of everything the governing body may do or leave undone, or that any member who presumes to disapprove of or criticize its actions is therefore disloyal.

My desire is certainly not to minimize but to increase the influence of the Society, and I do not think that by pointing out some of the causes that retard its progress I have done anything to diminish that influence.

Cheetham Hill, Manchester. W. WILKINSON.

Sir,—*Re* the subject of Mr. Wilkinson's letters, I quite and most emphatically endorse the statements he made in his letter, appearing February 13, and also those contained in that appearing to-day.

Let the Council and the Pharmaceutical Society act in such a way as really to represent the whole trade and then, and not till then, will it be really "efficient."

I have written to you before thus and my opinions are still unchanged, and are those of members and the trade generally, I believe, as Mr. Wilkinson points out in his letter of to-day.

16 *and* 17, *Cliffe High Street, Lewes.* W. T. MARTIN.

Dispenser.—There can be no doubt that the views expressed by you are correct, but it is difficult to persuade the public to act in accordance with them.

C. H. Ering.—Your letter has been handed to the Secretary.

M. P. S.—No doubt decomposition occurred in the almond emulsion. Try bitter almonds.

Inquirer (Barnsley).—We should not expect such a condition. Try the plan of shaking the liquid with some pulped paper and then straining through flannel.

H. T. W.—Consult a medical practitioner.

Saline.—(1) Sodium bicarbonate is permanent in dry air, but gives off carbonic anhydride at a red heat. (2) Tartaric acid melts at 170° C. (3) The use of sugar is optional.

A Country Chemist is recommended to bring any definite information he may possess as to breaches of the Pharmacy Act under the notice of the Registrar.

A. E. J.—The decision in your case seems to be strictly in accordance with the terms of the Act, though we confess we are unable to see in what the article differs from some of the others mentioned.

Cryptogamic.—The artificial acid may be used.

E. J. Evans.—(1) Apply to the Clerk of the Company. (2) A satisfactory knowledge of chemistry.

M. P. S.—Probably *Barbarea vulgaris*, but it is impossible to say with certainty in the absence of flowers and fruit.

G. D. Bowie.—(1) *Polyporus versicolor*. (2) The coloration is due to the mycelium of *Peziza æruginosa*.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Hart, Bennett, Barnett and Co., Unsuccessful Candidate, Jersey.

THE NEW FRENCH PHARMACOPŒIA.

Preliminary Notice.

The new work which from the present date authoritatively displaces the *Codex Medicamentarius* that has been official throughout France during the last eighteen years is the result of the labours of a Commission appointed by President Grévy in February, 1880. The constitution of this Commission is especially referred to on another page, and it need only be stated here that it included among its members men who are eminent in medicine, chemistry, botany, materia medica, and practical pharmacy. The Codex is written throughout in the French language, and in general appearance the new book resembles its predecessor, being printed on the same large octavo page, and following the previous typographical arrangements pretty closely. But a closer examination shows that a considerable alteration has been made in the general arrangement of a great portion of the text, to which more special reference will be made subsequently.

Probably the feature that will first attract the attention of most persons handling the book will be the occurrence of bands of red, white, and blue on the edges, due to the utilization of the republican tricolor as a means of marking off the divisions of the book, after the manner familiar to persons who use the Post Office Directory. These divisions are four in number, the first commencing with some preliminary matter and the last closing with a series of extracts from the laws and regulations concerning the practice of pharmacy in France. Between these lie the four parts of the Pharmacopœia, strictly speaking, devoted to (1) a List of Materia Medica, (2) Chemical Pharmacy, (3) Galenical Pharmacy, and (4) Veterinary Pharmacy.

The Preface is moderately brief, but well-written, and is signed by the President of the Commission. Then, under the title of "*Notions Préliminaires*," follow items of information respecting weights and measures, specific gravity and alcohometric tables, a table of solubilities, and another of equivalents and atomic weights, some of which had a place in the previous Codex. Two or three tables showing the relation of the gram to other French weights that have become obsolete are suppressed; but there remains one table that professes to show the relation of foreign medicinal weights to the gram which certainly shows an excess of conservatism. In it Great Britain and the United States are bracketed together as having the same medicinal ounce and pound, and it is further stated expressly that the pound consists of 5760 grains and is divided into 12 ounces. This was not correct when the previous edition was published in 1866, though perhaps the editors of that period might be excused for not taking cognizance of what had happened outside France within a couple of years; but the perpetuation of the mistake after an interval of twenty years is hardly creditable in an official work. Moreover, the same table attributes to Bavaria, Hanover and Prussia, as medicinal weights, pounds and ounces based upon a grain of a different value in each country, quite oblivious of the fact that since 1870 one Pharmacopœia has been authoritative throughout the whole of the German empire, and that the only measure of weight to be found in it has been the gram. Whilst upon the subject of measures it is worth mentioning, as illustrative of the difficulty with which the most scientifically worked-out systems displace old and familiar ideas, that even in the home of the metric system it is found necessary, on account of certain prescribers, to retain such measures as spoonfuls and glassfuls. All that can be done is to give them appropriate values, which differ, however, in some respects from those given in the Codex of 1866. A teaspoonful (*cuillerée à café*) of water is still defined as weighing 5 grams; but the weight of the dessertspoonful of water is now given as 10 grams; that of the tablespoonful (*cuillerée ordinaire*) as 15 grams, instead of 20 grams; and that of the glassful (*verrée*) as 120 grams, instead of 160 grams. The "handful," however, as a measure of seeds, leaves, etc., and the "pinch," as a measure of flowers, etc., are no longer officially recognized. In order to meet the difficulty attending the measurement of drops a table is given showing the weights of drops of different liquids and the number to a gram. These drops represent those falling from a glass tube terminated by a capillary opening, the exterior diameter of which measures exactly three millimetres. Twenty drops passing through this instrument at a temperature of 15° C. should weigh within two-hundredths of a gram.

The inconveniences attending the use of the degrees of an instrument so arbitrarily graduated as Baumé's areometer for indicating the densities of liquids were fully recognized in the previous edition and provision was made for its substitution. A further step is now taken, and densities in degrees Baumé are no longer given in the body of the work, so that although a table of equivalents is still provided for the sake of convenience, the time is probably brought nearer when the sign "B." will cease to perplex the English readers of French pharmaceutical works. It may be useful to mention that the instrument adopted instead, for liquids heavier than water, is the "densimetre" of Brisson, which is, in fact, an ordinary hydrometer, bearing the figure 1000 at the top of the stem to indicate the level to which it sinks in distilled water at +4° C., the other graduations corresponding to the increasing densities in thousandths. For liquids lighter than water, the centesimal alcohometer of Gay-Lussac is recognized, the zero in the graduation of which corresponds to pure water at 15° C., and the figure 100 to absolute alcohol, so that each degree represents 1 per cent. of absolute alcohol by volume, instructions being given for making the necessary corrections for temperature. A table is also given showing the quantity of absolute alcohol by weight in mixtures corresponding to these degrees, the contraction of acoholic mixtures, the coefficient for the correction of temperature from 0° to 30° C., and the weight of a litre of liquid of particular density in a vacuum and in air. Another table gives the quantities by weight of alcohol of any given degree and distilled water that require to be mixed to obtain a kilogram of alcohol of any of the strengths indicated in the Codex.

Passing now to the First Part of the Pharmacopœia it is found that this consists of a list of the substances derived from animals or plants which are employed in their natural state. In the Codex of 1866 a similar list was followed by one of substances derived from minerals and chemical products, but these articles are now included in the next division. The animal and vegetable materia medica is still very extensive, numbering about four hundred and seventy articles, although considerably over a hundred appear to have been omitted. Little comment respecting the numerous omissions is needed here beyond the remark that most of these articles could be very well spared; this is true especially of those derived from the animal kingdom, as will be admitted when it is mentioned that they include the frog, a species of viper, the oyster, animal kermes, and the wood-louse. The animal kingdom is, however, by no means abandoned, and among its representatives in the Codex are still to be found the concretions known as crab's-eyes, civette and the apple snail. Among the principal novelties in this list are boldo leaves, the flowering tops and seeds of *Cannabis sativa*, dita bark, eucalyptus leaves, potato starch, jaborandi leaves and podophyllum rhizome.

A glance at the Second Part is sufficient to show that here there has been a radical alteration in the arrangement. In the Codex of 1866 the articles not enumerated in one or other of the materia medica lists were grouped in no less than seventy-five chapters, the nature of which will be best indicated by quoting the titles of half a dozen of them: Simple Bodies, Mineral Acids, Sulphides, Salts with Vegetable Bases, Oils and Fats, and Syrups. As these chapters did not follow in alphabetical order according to their subjects, the device seemed an ingenious one for perplexing any person wishing to consult the work in a hurry. In comparison, therefore, the present arrangement seems preferable. It consists in dividing all these articles, together with those that previously constituted the inorganic list in the materia medica, into two large groups, one designated "Chemical Pharmacy," and constituting the Second Part of the book, and the other entitled "Galenical Pharmacy," and forming the Third Part. In these two parts the articles are arranged alphabetically, according to the individual titles in the Second Part and according to the titles of groups of preparations in the Third Part. This arrangement is fairly convenient in respect to the galenicals; but cannot be said to be so in respect to the chemicals, in consequence of the form of nomenclature adopted, in which only the vernacular is used, the acid radical in compounds coming first. Thus the list opens with "Acétate of Ammoniaque Liquide," followed by "Acétate of Chaux," and the other acetates; and after these come the acids. One result of this is to group all the saline compounds according to their acid radical, so that in order to ascertain what are the official saline compounds of a particular inorganic or organic base it will be necessary to consult the index, and even there the information is not always to be found. Another point that is noticeable is the maintenance of the term representing the oxide of the base in the names of the compounds of the alkalies and alkaline earths. It is a fair question, however, whether the Codex Commission might not have improved its work by conforming to the arrangement now general, according to which the materia medica and the preparations are brought into a single alphabetical list, in which the basic side of a compound regulates its position. At present the Commission will seem to many to have abandoned an untenable position, without having had the courage to continue the movement to its logical end.

As it is proposed to refer on future occasions to the articles in these two divisions in some detail, it will suffice to mention here in the briefest manner some of the principal additions that have been observed in the Second Part of the Codex, since these will to some extent indicate many of the probable novelties in the Third Part. Taking first the alkaloids, the Codex now includes apomorphine and its hydrochlorate, caffeine, conine hydrobromate, eserine and its hydrobromate and sulphate, hyoscyamine, narceine, pelletierine tannate, pilocarpine and its hydrochlorate and nitrate, cinchonidine sulphate and the basic and neutral hydrobromates, and quinidine sulphate. Besides these there have been added the ferrocyanhydrate, lactate, salicylate, hydrochlorate, tannate and two hydrobromates of quinine, hydrobromate of morphine and nitrate of aconitine. Other important organic compounds are crystallized digitalin, picrotoxin, picric acid, salicylic acid and sodium salicylate, ammoniated glycyrrhizin, thymol, chloral hydrate, iodoform, amyl nitrite, ethyl bromide and iodide, monobrom camphor and vaseline. There are four new lithium compounds, namely, the benzoate, citrate, carbonate and salicylate. Hydrobromic acid is supplemented by the bromides of barium, iron, sodium; and the iodides of ammonia and sodium are added. Then there are the hypophosphites of sodium and calcium, sodium chlorate and sulphovinate, calcium acetate, benzoate and lactophosphate, and red phosphorus.

NOTE ON A SAMPLE OF SOPHISTICATED SAFFRON.

BY J. HART, PH.C.

A few days ago my attention was drawn to a yellow powder at the bottom of a shop bottle containing saffron (*Crocus sativa*). The abundance of the powder (in proportion to the small quantity of saffron), together with its weight, induced me to make a thorough examination of it, and as I have not met with similar results (possibly owing to the want of indices and of more time to search the literature), the following remarks may be of interest:—

For the purpose of comparison, 10 grains of a very fine sample of saffron, recently purchased, were incinerated in a platinum crucible; the ash obtained weighed ·5 grain, equalling 5 per cent. The process was repeated with an exactly similar result. This corresponds with 'Pharmacographia,' which gives "5 to 6 per cent." as the ash of genuine saffron. Ten grains were then placed under a bell jar and allowed to dry until the weight became constant. The loss was found to be ·25 grain, thus bringing up the ash of a thoroughly dry specimen to 5·12 per cent.

The suspected saffron was very dry; but there was nothing in the colour to indicate the presence of mineral matter. There was no perceptible effervescence on the addition of dilute HCl, either in the powder or the saffron, proving absence of $CaCO_3$. Ten grains of the saffron, freed as much as possible from powder by shaking and rubbing, yielded 2 grains, equalling 20 per cent. of ash, showing 14·88 per cent. of adulteration, even after being freed from all loose powder, when compared with a dry specimen of pure saffron. Ten grains of the loose powder (containing a small quantity of saffron) were then incinerated and yielded 6·5 grains of ash, the bulk of which was insoluble in boiling HNO_3, and gave the characteristic flame of barium. An attempt to ascertain the exact nature of the ash from a further 10 grains of powder was frustrated by an unfortunate accident resulting in the loss of the whole. The remaining saffron and powder were then incinerated and the ash analysed with results as given below. This ash of course contains a proportion of normal ash, but the source of adulteration is proved beyond doubt.

Constituents of ash expressed as parts per 100:—

$BaSO_4$	64·28
$CaSO_4$	14·57
Al_2O_3*	10·71
Salts of K and Na	9·28
	98·84

Remarks.—It is of course impossible to accurately estimate the amount of adulteration, but I think it may be safely set down at from 25 to 30 per cent. I regret that I did not first make a microscopical examination, for although a large quantity of the powder must have fallen off, still sufficient was left on to have been indicated by the microscope. Both these samples were from houses of the highest standing, and in each case the top market price was paid, the adulterated specimen costing 50*s*. a few months ago and the pure 48*s*. per lb. in January last. Another proof is thus afforded, that neither the price paid nor the reputation of the wholesale house is at all times a sufficient guarantee of genuineness.

CONVALLARIA MAJALIS (LILY OF THE VALLEY).†

BY DR. SQUIBB.

Dr. Edward Drummond, of Rome, writes to *The British Medical Journal* (see No. 1194, November 17, 1883, p. 970), that he has lately met with an account of the use of this drug, in cardiac disease, as far back as the commencement of the seventeenth century, in an old Italian book of 'Commentaries on the Materia Medica of Dioscorides,' by Dr. Pietro Andrea Matthioli, published in Venice in 1621, and Dr. Drummond gives the following interesting translation:

"The Germans use lily of the valley to strengthen the heart, the brain, and the spiritual parts, and also give it in palpitation, vertigo, epilepsy and apoplexy; also as a remedy for the bites and stings of poisonous animals; to quicken parturition; and for inflamations of the eyes. For this purpose they are wont to prepare the wine from the flowers at the time of the vintage; and then infuse them in old wine for forty days in the sun, and subsequently distil and re-distil (but not many times), along with lavender-flowers, rosemary and other aromatics. They then preserve it as one of the most precious things to be found amongst medicines, and they call it 'aqua aurea,' and preserve it, in vessels of gold and silver, against sudden attacks. They even believe that, given to persons actually *in articulo mortis* it is able to prolong life for several hours. In this, however, they are not unfrequently deceived, as I have myself witnessed."

In the above translation it must not be taken for granted that the words "distil and re-distil" had their present meaning, for it is highly probable that they had not. Referring to Richardson and other authorities, it will be found that "to separate drop by drop," was formerly taken in a different sense, and had no necessary relation to rising in vapour and being condensed, or even to heat in any form. By the quotations given in Richardson, its present signification from some former more literal one can easily be traced, and in this translation it should probably be read as "percolate and repercolate" after the forty days' maceration.

Hence, it is probable that convallaria has been continuously used in medicine for several hundred years, and that its action on the heart has been long known. Its more modern and rational use in medicine, however, does not date back, so far as the writer knows, farther than a paper on the subject by Prof. Germain Sée in the *Bull. Therap.* for July, 1882. In connection with M. Hardy he investigated its physiological and therapeutic action at length, and very important and definite results were reported. Its effects on the heart and arteries, although similar to those of digitalis, were not identical, and were not produced in the same way, while it was free from some of the inconveniences and disadvantages of digitalis. It was not cumulative and explosive, as digitalis was reported to be. It did not interfere with digestion, but was perfectly well borne, the appetite rather increasing under its use, while the intestinal action was also improved. The diminution of the heart's frequency, under normal conditions, amounts to 10 or 15 beats per minute. Irregularity, especially of nervous origin, is lessened. Sensations of pulsations in distal vessels—*e. g.*, in the head—are removed by it. At the same time the force of the cardiac action is increased. It has a powerful diuretic action, increasing the amount of urine to about three times its previous volume (From *The Lancet*, August 26, 1882, p. 327).

This paper attracted considerable attention, and was followed by others in France, Great Britain and America. All agreed upon the potency of the drug as a cardiac agent. Some regarded it as an equal, and others as an inferior duplicate of digitalis. Some found it diuretic, others not at all so, while in a very considerable number of the trials the results were negative until toxic doses were used. Long ago it had yielded to chemistry two glucoside principles of very different and somewhat antagonistic action, and these, convallarin and convallamarin, were used separately, and the latter was alleged to be the cardiac agent, but with these also, discrepant results were obtained. In a year from the time of Professor Sée's paper it seemed doubtful if the convallaria was not a mere duplicate of digitalis, with the great disadvantage of being by no means so well studied or so well tried, yet stimulated into use by fashion and novelty, and by advertising.

If only a simple duplicate of digitalis, the already overloaded materia medica was much better without it. But if it differed materially in either quality or quantity of action, and was more free from collateral disturbance, the materia medica could not afford to lose the chances offered by it.

At about this period of its career the writer received a note from a very careful and close observer, saying that he considered it a valuable agent, which could not take the place of digitalis in his hands, but which had a place of its own to which digitalis had been applied, but to which it is less applicable, and asking the writer to make a preparation of convallaria for critical trial. This was in the early spring of 1883, and there was no part of the plant to be had in the American market. From the character of the plant, and from various considerations developed by the uses of the extract from its various parts by M. Hardy and others, the writer concluded that the root, if taken at the proper time, would be by far the best portion of the plant for medicinal use, and that a well-made fluid extract of the root would be far the best representative of the drug,—far better than the so-called active principles which, when divorced from each other, were found to yield such discordant results.

A florist was found who had some fine beds under cultivation, and when the roots had fairly sprouted they were taken from the ground, cleaned and dried by a gentle radiant heat. In drying they lost just about 75 p.c. of their weight, this loss not varying more than 1 to 2 p.c. in four separate parcels. The dried root and sprouts were then ground so as to pass through a sieve of twenty meshes, and were made into a fluid extract which represented the dried root minim for grain.

As a rule, cultivated plants are not as active, medicinally, as wild ones, but this was the best that could be done. The menstruum used for exhausting the root at first proved not to be a good one, and yet this fluid extract, in the hands of several good observers, proved moderately

* This contained a very slight trace of Fe.

† Reprinted from *Ephemeris*, January, 1884.

effective, and some discrepancies in the published statements were shown to be probably due to the use of preparations of different makers, or of different materials.

Specimens of this fluid extract were sent to several good observers, and in course of a few months results were obtained which, although not fully sustaining the character of the drug, were yet sufficient to warrant a more extended usage. By this time a parcel of foreign wild flowers and flower stalk had arrived. These were made into fluid extract with a different and better menstruum,—namely, the diluted alcohol of the U.S.P. of 1880. It was, however, pretty plain from the sensible properties that this was not so active nor so good a preparation as that from the root, and therefore that the root collected at sprouting should be preferred. A very few therapeutic trials seemed to confirm this opinion, and by this time some foreign root arrived, was made up and distributed, and the supply of this has now been kept up for several months to all who applied for it, thus gradually extending the number of those who were using this preparation, and adding them to the much larger number of those who were using the preparations of other makers, and who had used these long before this writer took up the subject.

Up to this time several competent and careful observers, —free from the prejudice of novelty, and from the still more dangerous prejudice of basing general conclusions upon too few cases,—have reported their experience in a guarded way. This experience is still discrepant, and therefore difficult to state, so that perhaps all that can be safely said, is that the general kind and direction of the results show that convallaria is worthy of a more extended use before it can be either fully accepted or discarded. It may be pretty definitely said that it is not a simple duplicate of digitalis, nor is it adapted to supersede that important agent in any large number of cases. Yet its use may serve to differentiate or discriminate between cases which have hitherto been classed together and all treated by digitalis, because there was no other agent that was applicable to any of the class.

If the uncertain indications from the use of convallaria thus far be not mistaken, the best that can be hoped from it is that it may materially aid physicians in splitting up the digitalis class into groups, some of which may be better managed by convallaria. It is also among the possibilities, if not among the probabilities, that it may prove either or both a substitute and adjunct to digitalis. There are many conditions in which digitalis fulfils all the indications required of it, but in which it cannot be continued in sufficient doses to maintain the good effects without disturbing the stomach and thus interfering with nutrition. In such, or in some of such cases at least, it may serve as a substitute or alternate. In other conditions which seem to indicate the effects of digitalis, but in which that agent does no good, or cannot be tolerated, convallaria gives a chance of relief where there may have been less chance without it.

Two or three years of careful observation, in good hands, extended over large numbers of cases, without prejudice, and with earnest investigation, will be absolutely necessary to establish the true and lasting character of convallaria, and it is this consideration which induces the writer to add his supply of a well-made fluid extract from good material to those of other makers who long preceded him in supplying it.

The dose of convallaria is, of course, the quantity which will give the special or physiological effect, and this will be different in different cases. But the dose to begin with, and that which will be effective in some cases, is about 24 grains in the twenty-four hours. And as the fluid extract represents the drug minim for grain, the dose of that will be as many minims,—say 6 minims every four hours, or 8 minims three times a day,—the size or the number of the doses to be increased until some effect is obtained.

The fluid extract is miscible with water, and though it does not make a clear solution, the precipitate which settles out is probably but not certainly inert. A good way to administer it is to put a measured quantity in a wine glass and add as many teaspoonfuls of water as may make up the number of doses required when given from the same teaspoon. For example, a fluid drachm is measured into a wine glass, and seven teaspoonfuls of water, or wine, or diluted alcohol are added and the mixture well stirred. Then using the same teaspoon, and stirring well at each dose, if water be the diluent, it is given in teaspoonful doses, which will be nearly eight minims each, farther diluted if desired at the time of taking it.

If the drug is to have a fair chance, there can be very little doubt that a well-made fluid extract of the root collected at the proper season is the best form in which to use it. In all drugs, the active principles of which are neither alkaloids nor acids, but are of that indefinite class called glucosides for want of a better generic name, it is pretty certain that these glucosides do not fully represent the drugs,—nor even well represent them. And when two or more glucosides are obtained from the same drug, the doubt is much strengthened. No one knows,—be he ever so good a chemist,—where the molecules of complex organic substances will split until he tries them, and therefore what he gets is often empirical, and may be the result of his chemical process, so that a different process may give different results. For example, Walz, in 1858, obtained from convallaria two glucosides which he named "convallarin" and "convallamarin." Dilute acids again split both of these into other bodies by subtracting a molecule of sugar, and one of the resulting bodies, *minus* half a molecule more of sugar, leaves the formula of the other original glucoside. Hence the inference that neither convallarin nor convallamarin exist in the plant, but that they are the result of the splitting-up of more complex molecules by chemical means. No one has ever proved that either of them pre-existed in the plant, while the physiological action of the plant is not represented by the action of the two glucosides as given.

THE USE OF LITMUS, METHYL ORANGE, PHENACETOLIN AND PHENOLPHTHALEIN AS INDICATORS.*

BY ROBERT T. THOMSON.

(*Concluded from p.* 705.)

X.—*Effect of the Phosphates of the Alkalies.*

As the normal phosphate of potassium is generally found to the extent of 1 or 2 per cent. (it has even been found as high as 7 per cent.) in commercial carbonate of potash, it is a matter of great importance to know what proportion of the potash, existing as phosphate, is determined by standard acid. I found that the phosphates of potassium, sodium and ammonium acted in the same manner towards the indicators when titrated with standard acid, and will, therefore, only quote the double series of experiments made—the one with normal sodium orthophosphate (Na_3PO_4), and the other with the ordinary disodium hydrogen orthophosphate (Na_2HPO_4). The crystallized form of the former of these salts was prepared by dissolving a weighed quantity of the latter in boiling water, adding the proper proportion of hydrate of sodium, and allowing to crystallize out. After recrystallizing both of these phosphates, a portion of each was ignited to obtain the real amount of dry salt in each, and solutions made of such a strength that 50 c.c. contained in the one case 2·05 gram Na_3PO_4 (equal to 1·162 gram Na_2O), and in the other 1·775 gram Na_2HPO_4 (equal to ·775 gram of Na_2O).

When *litmus* was used in the titration of the normal phosphate, the blue colour remained intact until about 16 c.c. of the normal sulphuric acid were added, when it

* Read before the Chemical Section of the Philosophical Society of Glasgow, January 22, 1883, and reprinted from the 'Proceedings.'

became purple, and, on further addition, slowly passed into red, the change being complete at about 24·9 c.c. This is equal to ·772 gram of soda, which is practically two-thirds of the total soda. The point at which the red colour was fully developed could not be ascertained with any degree of accuracy, even when a solution of reddened litmus was used for comparison, as the change was so very gradual. The mono-acid phosphate consumed 12·4 c.c. of the standard acid, thus agreeing with the result of the normal phosphate.

Methyl orange gives as delicate an end-reaction as with hydrate of sodium. The results were slightly higher and nearer the truth than those obtained with litmus, 25·05 c.c. being required in the one case and 12·6 in the other.

Phenacetolin.—With this indicator the same number of c.c. were necessary as with litmus, and, like the latter, changes gradually in colour, so that the point at which excess of acid is added is somewhat difficult to catch. There is, however, a peculiar phenomenon to be noticed with regard to this indicator. The normal phosphate, like hydrate of sodium, only brings out the scarcely perceptible yellow colour; but, after the addition of about 11 c.c. of the normal acid, the permanent pink colour is formed. In fact, the first-named salt acts towards phenacetolin as if it were a mixture of hydrate and the mono-acid phosphate of sodium. The latter salt produces the pink colour at once.

Phenolphthaleïn again acts in an entirely different way to the other indicators. We have seen before that $NaHCO_3$, NaHS, and Na_2SO_3 are neutral to this indicator, and to these must now be added Na_2HPO_4; while $NaHSO_3$ and NaH_2PO_4 are neutral to litmus, methyl orange, and phenacetolin—$NaHCO_3$ and NaHS being alkaline, and not requiring to be decomposed by boiling before determining the alkali in them by test acid. It will be observed that, in each case, there is exactly an atom of sodium of difference, the phenolphthaleïn being invariably the weaker indicator.

In titrating the normal phosphate, 12·65 c.c. of the test acid were required to discharge the red colour in the cold, and 13·7 c.c. in the boiling solution, the mono-acid phosphate requiring only ·25 in the cold and 1·4 in the hot. In each case, on cooling and titrating back with caustic soda, the same result as was obtained at first in the cold solution was brought out. These results show that when phenolphthaleïn is employed, one-third of the soda in normal phosphate of sodium is estimated by standard sulphuric acid, and only a trifling portion of that existing as the mono-acid phosphate.

Table VII.

Results obtained in the titration of normal sodium phosphate and disodium hydrogen phosphate by normal acid.

Na_3PO_4 used for each test	2·050

Phenolphthaleïn (boiled) . . .	13·7	·425	1·4	·043

XI.—Effect of Silicate of Sodium.

A preliminary test was made of the value of litmus for the estimation of soda in silicate of sodium, by taking a quantity of hydrate of sodium of known strength, dissolving some silica in it, and then determining the soda. The exact amount of soda used was found, and the estimation made by litmus was taken as the standard of comparison with the results obtained with the other indicators. Five grams of commercial liquid silicate of soda were employed, and 15·05 c.c. of normal acid were consumed with litmus as indicator, the end-reaction taking place with great distinctness.

With *methyl orange* also a very distinct end-reaction was obtained, and 15·1 c.c. were consumed—a result closely corresponding with the former one.

Phenacetolin gave a dark pink colour with the silicate of sodium, but this became yellowish towards the end of the test, and the change was not very distinct. 15 c.c. of the acid were necessary, which does not materially differ from the quantities obtained with litmus and methyl orange.

Phenolphthaleïn.—The red colour produced by the phenolphthaleïn was slowly destroyed on running the acid into the cold silicate solution, 12·7 c.c. only being required. When boiled, the colour returned, but was dispelled when 13·5 c.c. had been added. These results are considerably below the truth.

Table VIII.

Results obtained in the titration of silicate of sodium ($Na_2Si_4O_9$).

Phenacetolin.	15·0	·464
Phenolphthaleïn (cold) .	12·7	·393
Phenolphthaleïn (boiled).	13·5	·418

XII.—Effect of Alumina.

Soluble alumina, like silica, is seldom or never absent from caustic soda or potash. The experiments were made with an excessive quantity of alumina, the proportion used being equal to about 8 per cent. in an average strength of caustic soda. A quantity of pure hydrate of aluminium, equal to ·515 gram Al_2O_3, was prepared from alum by precipitation with ammonia. This precipitate was redissolved, reprecipitated, washed thoroughly, dissolved in 125 c.c. of normal caustic soda and made up to 250 c.c. with water. Fifty c.c. of this was employed for each test and contained ·775 gram of soda, and ·103 gram of alumina.

Litmus.—When litmus is used 25·25 c.c. of the normal acid were consumed, in place of 25 required when no alumina was present, nor did the end-reaction come out very distinctly.

Methyl orange.—After a little more than 25 c.c. of the acid had been consumed, the alumina was all precipitated, and then gradually dissolved, the pink colour at first produced being quickly dispelled as the acid combined with the alumina. A decided and permanent change occurred when 30·7 c.c. had been added. This gives ·951 gram of soda, as against ·775 really present, and if the difference be calculated to alumina it shows ·097 gram of the latter compound instead of ·103. It is thus evident that nearly the whole of the alumina has been estimated along with the soda.

With *phenacetolin* and *phenolphthaleïn*, the real amount of soda used was obtained. The only effect of the precipitated alumina is to obscure the end-reaction slightly.

Table IX.

Results obtained in the titration of aluminate of soda.

XIII.—Effect of Nitrite of Sodium and Potassium.

A solution of nitrite of potassium was prepared by decomposing with chloride of potassium a known weight of nitrite of silver, which was precipitated from a solution of nitrite of sodium. Twenty c.c. of this nitrite of potassium liquor contained 1·7 gram of KNO_2, and this quantity, diluted to 100 c.c. was employed for each test. The nitrite was found to be quite neutral to litmus, phenacetolin and phenolphthaleïn. With methyl orange, however, the pink colour was not produced even after adding 30 c.c. of normal acid, but seemed to be destroyed at once by the liberated nitrous acid. Another quantity, containing ·085 gram of the nitrite in the 100 c.c., gave a pink colour with ·2 c.c. of acid, but this was slowly dispelled on standing a few minutes, leaving a pale yellow colour. Nitrite of sodium acts in the same way towards the indicators as nitrite of potassium. Nitrites are sometimes found in small proportion in caustic soda and potash.

XIV.—Determination of Soda in Borax.

The solution of borax employed contained 1·683 gram of pyroborate of sodium in 50 c.c., the quantity used for each test.

With *litmus*, the blue colour began to purple when 13 c.c. had been added, but the change was not complete until 16·65 in the one case, and 16·6 c.c. of normal acid in the other, had been consumed. This shows ·516 and ·514 gram of soda, as against ·516 really present. The end-reaction, however, is very indistinct.

Methyl orange is by far the best indicator for the estimation of soda in borax, and is indeed perfect in that respect. The change in colour at the end of the experiment was very sharply defined. The results agreed closely with those of litmus.

Phenacetolin.—Like litmus, the colour of this indicator slowly changes, and a good end-reaction is therefore impossible. The whole of the soda can be estimated by it.

Phenolphthaleïn is utterly useless for the purpose under consideration. The red colour disappears before half of the soda is determined in cold solutions. When boiled, a much higher result is obtained, but still very far below the truth.

XV.—Determination of Free Sulphuric, Nitric, and Hydrochloric Acids.

It is quite plain from the results obtained when testing the behaviour of the sulphates, chlorides, and nitrates of the alkalies with the indicators under consideration, that these acids can be determined by a standard caustic alkali, excepting that ammonia cannot be used with phenolphthaleïn. Carbonate of sodium can be used in the cold if methyl orange is employed, and in the case of phenacetolin the caustic potash or soda should contain a little carbonate of potassium or sodium, so that the carbonate or bicarbonate will be formed when the end-reaction is reached, and the dark pink colour will be produced.

XVI.—Determination of Free Oxalic Acid.

A normal solution of pure oxalic acid was prepared, and 20 c.c. of this was employed for each test.

With *litmus* the end-reaction was very well defined, and exactly 20 c.c. of normal hydrate of sodium were consumed, thus giving exactly the amount of oxalic acid.

Methyl orange.—It has been pointed out by Lunge that methyl orange must not be employed when oxalic acid is titrated, and from the following test it is evident that it cannot be relied on. When 12 c.c. of the normal alkali were added the pink colour began to fade away, and was completely destroyed after the addition of 18 c.c.

Phenacetolin.—The addition of 19·8 c.c. produced a very faint pink colour, which was not fully developed till 20 c.c. had been consumed. This indicator cannot, therefore, be recommended as useful for the titration of oxalic acid.

Phenolphthaleïn, on the contrary, works admirably, the end-reaction being as delicate as with the mineral acids. The result agreed with that of litmus.

Table XI.

Determination of oxalic acid.

$H_2C_2O_4$ used for each test . . . ·900 grams.

Name of Indicator.	C.C. of Normal NaHO consumed.	Grams $H_2C_2O_4$ found.
Litmus	20·0	·900
Methyl orange .	18·0	·810
Phenacetolin . .	19·8	·891
Phenolphthaleïn .	20 0	·900

XVII.—Determination of Acetic Acid.

The sample of acetic acid in which the free acid was determined showed a specific gravity of 1·0472 at 15° C., which is equal to, according to Oudemann's table, 35·02 per cent. of $HC_2H_3O_2$. One hundred grams of this acid were made up to 1 litre with water, and 50 c.c. used for each titration, the caustic alkali used being standardized with normal sulphuric acid.

Litmus.—On adding the normal caustic soda, the red colour remained intact, but towards the end of the experiment became purple and almost blue before the end-reaction was accomplished. The last change in colour could only be observed by comparison with a blue litmus solution of the same strength as the liquid operated upon. 29·15 c.c. were consumed both with this experiment and with one tested with litmus paper, 1·749 gram of acetic acid being obtained in each case.

Methyl orange is totally useless as an indicator in the estimation of acetic acid, only 3·5 c.c. of the alkali being consumed.

Phenacetolin.—The addition of 28 c.c. produced a pale rose colour, but the change was very undecided. This indicator is not adapted for this purpose.

Phenolphthaleïn is well fitted for use in the estimation of free acetic acid by caustic soda, as acetate of sodium is perfectly neutral to it, while that salt is alkaline to litmus. Several tests gave 29·2 c.c. of normal alkali consumed—these results being slightly, but quite distinctly higher than those obtained with litmus. The end-reaction is as delicate and sharply defined as in the determination of the mineral acids. If the solution in which the acetic acid is to be determined is dark coloured (as in some vinegars), it may be highly diluted, as dilution has little or no effect on the delicacy of phenolphthaleïn.

Table XII.

Determination of acetic acid.

Name of Indicator.	C.C. of Normal NaHO consumed.	Grams of $HC_2H_3O_2$ found.
Litmus	29·15—29·15	1·749—1·749
Methyl orange .	3·5	·210
Phenacetolin . .	27·8	1·668
Phenolphthaleïn .	29·2—29·2	1·752—1·752

XVIII.—Determination of Tartaric Acid.

1·5 grams of pure and dry tartaric acid were used for each experiment. The solution tested with *litmus* as indicator began to get purple after the addition of 19 c.c. of normal caustic soda, but the change to blue was not complete till 20 c.c. had been consumed, the tartaric acid found being exactly equivalent to the quantity taken. As with oxalic and acetic acids, *methyl orange* gives very low results, 16 c.c. only being required to dispel the pink colour. The tartaric acid found by *phenacetolin* was slightly, but perceptibly, under the truth.

Phenolphthaleïn in this case, as with acetic acid, is the only perfect indicator among these four. Although the results obtained are much the same as those with litmus, the unimpaired delicacy of the end-reaction gives phenolphthaleïn a great advantage over the former indicator.

Table XIII.

Determination of tartaric acid $H_2C_4H_4O_6$ used for each test, 1·5 gram.

Litmus	20—20	1·500—1·500
Methyl orange .	16	1·200
Phenacetolin . .	19·85	1·488
Phenolphthaleïn .	20—20	1·500—1·500

XIX.—Determination of Citric Acid.

The sample used for the following tests was found to be free from impurity; but, as the water of crystallization varies to some extent, it was determined by drying for about twelve hours between 50° and 60° C., and then gradually raising the temperature to 100°. 8·53 per cent. was obtained, which is slightly lower than the theoretical proportion, 8·57 per cent. As 14 grams were made up to 200 c.c., 20 c.c. contained 1·2806 gram of dry citric acid ($H_3C_6H_5O_7$), this being the quantity operated upon. The normal caustic soda was standardized by normal sulphuric acid.

Litmus seems still to be considered the best indicator for the estimation of free citric acid, but it is a very defective one. In the first place, it gives a very indefinite end-reaction, and, in the second, the normal citrate of soda formed during titration is so alkaline as to preclude the use of sulphuric or any other mineral acid in the standardizing of the caustic soda. Pure citric acid must in that case be employed as the standard, and this entails the testing for impurities, and the tedious estimation of water described above. Allen, in his 'Commercial Organic Analysis,' vol. i., p. 263, noticing these points, observes that neither logwood nor cochineal give sharp end-reactions, and recommends the use of carefully prepared litmus paper. In the two tests I made both litmus solution and paper were used, the last change in colour of the former being observed by placing it side by side with a litmus solution of equal strength, to which a little alkali had been added. The results were identical, 19·7 c.c. of the normal alkali being consumed in each case. This shows ·02 gram too little of citric acid, and is to be attributed to the alkalinity of the citrate, as sulphuric acid was made use of in testing the standard caustic soda.

Methyl orange and *phenacetolin* were found to be of no value in the titration of citric acid, 9 c.c. being consumed with the former and 17 with the latter.

Phenolphthaleïn.—This indicator is again distinguished from the others by its great delicacy in the determination of free citric acid, as it is in that of tartartic and acetic acids. Several tests were made, and in every case 20 c.c of the normal acid were consumed, giving results extremely close to the real amount of citric acid present, Phenolphthaleïn has thus two advantages over litmus for the determination of citric, tartaric and acetic acids; first, it gives a sharply defined end-reaction, and, second, sulphuric acid can be employed in standardizing the caustic soda.

Table XIV.

Determination of citric acid, sulphuric acid being used for the standardizing of the normal caustic soda.

$H_3C_6H_5O_7$ used for each test . . . 1·2806 gram.

Litmus	19·7—19·7	1·2608—1·2608
Methyl orange .	9·0	·5760
Phenacetolin . .	17·0	1·1000
Phenolphthaleïn .	20·0—20·0	1·2800—1·2800

Litmus and *phenolphthaleïn* were further tested with a sample of lime juice, in order to make certain that a similar difference in result would be brought out when these indicators were applied to the determination of citric acid in this substance. Of course the other free acids existing in the juice would be included in the result. Ten c.c. of the sample, measured at 15·5° C., were employed.

Litmus paper was used as indicator, as the yellow colouring matter of the lime juice darkens so much as to make litmus solution useless. 13·0 and 13·05 c.c. of normal alkali were consumed, which give 36·5 grains of dry citric acid per ounce, 30 grains per ounce being the Board of Trade standard.

Phenolphthaleïn.—With this indicator the most convenient quantity to use is 10 c.c. of the juice, diluted to 150 or 200 c.c. As the yellow colouring matter becomes darker towards the end of the experiment, the end-reaction is not quite so delicate as in a colourless solution, but can still be recognized without the least difficulty. 13·25 c.c. of the normal alkali were consumed in each case—these results being equal to 37·1 grains of dry citric acid per ounce.

AMERICAN DRUGS.*

BY J. MOELLER,

Botanist and Microscopist of the Imperial Forest Institute, Mariabrunn, near Vienna.

(*Continued from page* 704.)

5. HERBA FRANKENIÆ GRANDIFOLIÆ (YERBA REUMA).

The drug consists of all that part of the plant above ground, gathered at the time of blooming. The stem is round, the leaves are disposed in alternate pairs opposite one another. They are spathulate, fleshy, smooth-edged and with but a single nerve. At first they are hairy, as are also the calyces and youngest shoots, but as

* Reprinted from the *Therapeutic Gazette.*

the leaf grows older it becomes smooth, except at the base, where a few remaining straggling hairs give it

Fig. 8.—Branch of *F. grandifolia*: nat. size.

the appearance of being slightly ciliated. Each leaf-sprout ends in a flower (Fig. 8), and the axils of the short, whilst the terminal blossom are generally furnished with two flowers, which are in reality shoots of a higher order, with contracted internodes. The terminal two pairs of leaves form a border around the tubular four-ribbed and four-toothed calyx, from which the four pale-red petals scarcely protrude at all.

The plant when dried has a greyish green colour, similar to the oil-willow (*Elæagnus*), but less silvery. It is odourless and tastes saltish, owing to an external saline incrustation, freed from which the plant proves tasteless.

The family of Frankenia, to which the yerba reuma belongs, is the only representative of the order of Frankeniaceæ, to which the indigenous families of Cystinaceæ, Droseraceæ and Violaceæ belong. *Frankenia grandiflora* (Cham. and Schl.) is indigenous to the sea-coast of lower California where grass grows but in winter. It is found even on the mountain slopes. It is a small, scrubby plant, having a short stem with but few branchlets, and is about 15 cm. in height. It is vulgarly known as "river grass" and was known to the early Spanish settlers as being capable of affecting the mucous membranes, a quality which it owes to the tannin and sodium salts which it contains.

Fig. 9.—Forms of *Jacaranda procera* leaves: nat. size.

Professor Carl Jungk (*Therapeutic Gazette*, 1882, p. 60) found:—

	Per cent.
Tannin forming a bluish precipitate with iron salts, nearly	6·000
Chloride of sodium	28·049
Chloride of magnesium	1·350
Sulphate of lime	1·474
Sulphate of sodium	2·547

It is claimed that the liquid extract, properly diluted, which this plant furnishes, is used with satisfactory results in cases of chronic catarrh of the nose, fluor albus and gonorrhœa, in its latter stages. It has also been given internally for catarrh of the digestive organs, but as yet the results obtained in this direction are not very definite even to the Americans.

6. FOLIA JACARANDÆ PROCERÆ (CAROBA).

The dried, well-preserved leaves are bright-green or brown in colour, varying in form and size (Fig. 9), but in no other particular, and therefore evidently all belonging to the one family. They are inclined to develop unsymmetrically, particu'arly towards the base of the leaf. They are more or less leathery, slightly bent downwards at the edges; the upper surface is smooth, the lower covered with a velvet-like covering, particularly towards the edges and along the nerves. The leaf-stems are very secondary nerves form slight anastomoses towards the rim of the leaf.

Microscopic Characters.—The cuticular covering on the upper surface of the leaf is several times stronger and thicker than that on the lower surface. The palisade layer is single, the mesophyll rather thick. The epidermis (Fig. 10) is, on both sides, composed of large irregular cells with many pores on the lower surface. These leaves are characterized by two kinds of trichomata which occur on both sides.

The first of these are conical thread-like hairs composed of but one cell, broad at the base, tapering gradually to a blunt point, 0·5 mm. and more in length, and thick walled; the others are round, cake-shaped glandular hairs, composed of six to eight cells arranged together in a star-shape (0·05 mm. in diameter) with a yellowish amber-like secretion.

The drug is odourless; when chewed it has a bitter and astringent taste. In 1828, Dr. Schimmelbusch first introduced it into Germany, where, however, it was soon forgotten. Some fifteen years ago it was again heard of there as a blood purifier and diuretic. It was also recommended, to be used both internally and externally, in syphilis. In 1867, Hager (*Pharm. Centralh.*, 1867, No. 3) described a sample sent him from St. Petersburg, consisting of five different and apparently entirely distinct sorts of leaves, whence he concludes that these leaves belong to five different Bignoniæ. I do not think from the specimens before me that this conclusion is warrant-

Fig. 10.—Aspect of under side of leaf.

able, though it may be quite probable that the gatherers may occasionally throw similar leaves of different, but closely allied plants, into the same basket. *Jacaranda procera*, Sprengel (*Bignonia copaia*, Aubl., *Bignonia caroba*, Vellos, *Kordelesteis syphilitica*, Arruel), a Brazilian bignonia, called by the inhabitants caroba, carobinha, caroba mirim, caroba minda, is said to be the parent plant.

Theo. Peckolt has subjected the bark and leaves of the caroba to a very searching analysis, and has found that the former possesses more carobin, the latter more aromatic substances. His analysis resulted as follows:—

	Leaves	Bark
Cellulose and water	853·304	885·090
Crystallized carobin	1·620	3·000
Carobic acid, crystallized	0·516	—
Steocarobic acid, crystallized	1·000	—
Carobon, balsamic resinous acid	26·666	—
Caroba resinous acid, odourless	—	2·000
Resin of caroba, tasteless and odourless	33·334	5·000
Caroba balsam	14 420	—
Bitter substance	2·880	2·830
Extractive substance	10·550	19·530
Extractive substance and organic acids	10·000	—
Caroba tannic acid	4·390	4·800
Glucose	—	1 650
Chlorophyll and wax	9·000	—
Albumen, starch, dextrin, salts	32·120 }	76·100
Calcium malatum	0·200 }	

O. Hesse (*Leibig's Ann. d. Chemie*, 1880, p. 150) has made diligent though futile search for alkaloids in these leaves, coming to the conclusion that their entire efficacy has been considerably exaggerated. It had been supposed that they were descended from a common ancestry with the Pareira bark, an error probably born of the fact that both possess like qualities as a drug.

Peckolt's "carobin" forms felt-like glittering crystal needles, is odourless, and has an alkaline taste, with a slightly bitterish after-taste. Heated upon a platinum foil, it melts into a clear liquid, and burns with a bright flame, leaving no residue. It cannot be sublimated. It is insoluble in ether or alcoholic ether but is very slightly soluble in cold water or cold alcohol; easily soluble, however, in boiling water or hot alcohol, again crystallizing upon cooling. The solution will turn turmeric paper brown. The foregoing table shows that the amount of alkaloid in the bark is nearly double that found in the leaves, whilst the former is wholly destitute of all aromatic substances. Since it is the leaves only that are in use as a drug, we must look upon their aromatic component parts as representing their most prominent curative properties. The name caroba has an unusually manifold signification. With us, as is well known, the fruit of *Ceratonia Siliqua*, L., carobs or carubs, a sort of acorn (*Pistacia terebinthus*), are known to commerce as carobs or carobbs. In Brazil they have also:—

Caroba de flor verde; *Bignonia quinquefolia*, Vell. (*Cybistax antisyphilitica*, Mart.).
Carob-assú: *Jacaranda subrhomba*, DC.
Caroba boanca: *Sparattosperma lithontripticum*, Mart.
Caroba do campo: *Bignonia nodosa*, Mans.
Caroba des paulistas: *Jacaranda oxyphylla*, Cham.
Caroba guyra: *Bignonia purgans*.
Caroba preta, carob-assú.

All the different kinds of carobs are used by the Brazilians as medicaments, and Peckolt (*Zeitschr. d. allg. österr.*, Ap. V., 1881, page 480) thinks they are in every way preferable to sarsaparilla. A certain syphilitic affection of the skin prevalent amongst the negroes, and called Bobas, is often cured by means of a preparation called "Massa de Dr. Alves Carneiro," which is composed as follows:—

℞	Fol. carob. pulv.	90·0
	Sarsaparillæ pulv	30·0
	Fol. sennæ pulv.	30
	Calomelanos	2·0
	Syrup. simpl. q. s. ut. ft. electuar.	

D. S. A teaspoonful morning and evenings with caroba tea.

Peckolt prescribes caroba balsam in doses of 1·0 g. as a tonic, and also as an external application for wounds; carobon in doses of 0·1 g. for affections of the skin, and carobin in doses of 0·5 g. for syphilitic and scrofulous affections.

These mere indications are not sufficiently comprehensive, nor have any pharmacodynamic experiments as yet been published on this subject that can pretend, in any reasonable degree, to satisfy the demands of science and research, which is indeed a rather remarkable circumstance in view of the reputation and popularity of this drug.

(To be continued.)

REFINING OF SHELLAC.*

BY E. L. ANDÉS.

The crude shellac is refined in the following way:—One and a half kilos. of soda are dissolved in 45 litres of water contained in a small boiler or kettle; 5 kilos. of the crude shellac are added in small quantities at a time. This turbid solution has the characteristic odour of shellac and a violet-red colour. The liquid is boiled for a few minutes, and, while hot, a wooden air-tight cover is cemented on the vessel. When the liquid is quite cold, the cover is removed, and the thin cake of fat which is found on the surface is separated. The solution is filtered through linen, the clear filtrate slowly decomposed with dilute sulphuric acid, and the resulting shellac washed with water until no acid reaction remains. The washed resin is now pressed and melted in boiling water, when it can be shaped with the fingers. This shellac is cooled in water containing glycerol, and, when hard, is dried. The refined shellac forms yellowish-white glistening tufts or bars which, when dry, are yellowish-brown; it should entirely dissolve in alcohol.

THE PRESS ON THE SALE OF POISONS.

From the SATURDAY REVIEW, *March* 8.

Public attention has been attracted so much of late to Ministerial messes, to African massacres, and Fenian explosions, that there seems to have been very little to spare for a crime probably unequalled in England since the days of Palmer at Rugeley. A series of the most atrocious murders has been detected at Liverpool, where for a paltry gain, two women have poisoned their nearest and dearest relatives. They were found out after a long career of probable but unascertained crime. One of them it is reported, confessed as much. There must, we feel sure, be numberless undetected cases as long as the sale of poisons is permitted as at present. The Liverpool poisoners might have gone on with their operations for years to come if it had not been that long impunity produced carelessness and carelessness clumsiness. So far as the law would have interfered they need never have experienced any difficulty in obtaining their supply of drugs. That they have been found out, convicted, and executed is a small matter. They can be hanged but once, and the investigation and trial went into but one case. But the whole affair reminds one of the danger incurred by the public owing to the present laws regulating the sale of poisons. The question of insurance is a serious one, but we need not enter upon it here. The question of the sale of poisons is a much more serious one, and just now the law is practically in abeyance as regards it.

We are therefore glad to hear that Government has taken up the subject. A Bill is before them, and will shortly be brought into the House of Commons. The Act of 1868 is a dead letter, yet it is the only protection we have at present. The older and more respectable chemists, with their full pharmaceutical licences, are being superseded by stores, grocers, and all kinds of unauthorized dealers. The old-fashioned chemist could and did know or guess what was in these compounds; he could and did exercise his judgment in selling them, so that no harm done by them could be brought home to him. But the association which manages a co-operative store, or the uneducated dealer in drugs, or the grocer's assistant who can now sell them, are altogether in the dark, and may provide a sick man with the very drug required to "complete the case." There is much, in fact, to be said against the entire system of stamping the so-called patent medicines. The royal arms on the cover give them a kind of Government sanction, which undoubtedly imposes on the uninformed. That the same paternal and benevolent body which insists on vaccination, pure milk, and sanitary arrangements in general, gives its official stamp to many dangerous narcotics and to virulent poisons supposed to counteract gout, cancer, and other diseases is enough with many people to recommend them as innocuous. Professor Attfield wisely suggests, and not an hour should be lost in adopting the suggestion, that the stamp should be abolished, and that the loss of revenue thus occasioned should be made up in a greatly increased charge for licences to sell patent medicines. As a fact, there is no real patent. If the inventor of a nostrum was obliged to register the drugs he uses and the process, as in ordinary patents, the case would be very different. Some old medicines were thus entered on the patent books years ago. But the modern quack medicine is a secret. We cannot expect every one who sells a bottle with a Government stamp on it to go to the expense of having the stuff analysed. Patent medicines may remain as they are—proprietary; but they should not have the sanction implied—in the minds of the general public, at least—in bearing a Government label. A patent medicine containing poison should be labelled poison, and it should be labelled, not by the retailer, but by the original maker, so that in case of harm ensuing from the use of it the retailer may have his remedy against the maker. There is no inherent difficulty in such an enactment. The retailer of watered milk, if he is fined, can recover against the producer under the Sanitary Acts; and it would be easy to make a similar arrangement in the case of dangerous medicines.

There is another point to which attention should be directed. At present the wholesale houses have no restriction placed on the sale of any poison which they can sell to the retailer or to a medical man. The case of Dr. Lamson will be remembered. He applied to a chemist for aconitine. It was refused; and he then went to a wholesale house in the City and obtained what was sufficient for his purpose. True it was only one grain; but that would be enough to poison half a dozen adults. This was, therefore, strictly speaking, a wholesale transaction, and as such was very severely commented upon by the learned judge who tried the case at the Old Bailey. The greatest difficulty, however, will be found in dealing with what are sometimes described as statutory poisons. These are a very frequent cause of accidents. A metal-worker sends out for a few pence worth of vitriol. It is probably brought him in a cup. It is set on the table among the children. The utmost danger is incurred. The action of vitriol is so pronounced that even a child is not likely to swallow much; but a poisonous dose of carbolic acid may be taken without any immediate inconvenience, and the number of fatal accidents from this cause alone is sadly on the increase. When a chemist sells it, he labels it; but the drysalter has it among his oils and varnishes, and sells it without a word of warning to the buyer as to its dangerous qualities. In cases like these, since we cannot prohibit the sale of drugs necessary in the arts, we should insist on their being at least labelled "Poisonous" as a warning. It is not possible for the law to prevent lawless people from committing crime, but it is very possible to mitigate the chances of accidents. If a man must have arsenic to commit suicide or murder, he will get it, like Mrs. Flanagan, from fly-papers, or perhaps from wall-papers. We can only deter him by the example shown at Liverpool on Monday. But the state of the law is to blame when a child swallows a mouthful of vitriol, or when sugar of lead is put into a pudding. We may go further, and refer to the enormous infant mortality caused by the administration of various kinds of soothing syrups. One well-known medicine of this kind is credited with a round dozen of deaths annually. Scarcely less shocking is the mortality from over-doses of narcotic poisons among adults, and it is reported to be largely on the increase. These are things which should not be allowed to happen, yet they do happen constantly and are reported daily in the papers. It is much to be hoped that the Bill when it comes before the House may be found to contain full provisions on these points, as well as on the licensing question and the other incidental matters of minor importance. The State is directly to blame when a preventable accident occurs, and it is indirectly to blame when the posioner finds the drug he wants ready to his hand.

THE NEW FRENCH CODEX.

AFTER three or four years devoted to the labour of revision, a new edition of the Codex Medicamentarius, or French Pharmacopœia, has just been published and will be binding on the pharmaciens of France on and after to-day. Intercommunication between the countries lying on either side of the English Channel has in recent years undergone such enormous development that this work will possess more of interest even than its predecessor for British pharmacists, many of whom will have to dip into its pages for the information necessary to enable them to dispense prescriptions that will be soon coming into their hands in the ordinary course of business. Even where this is not the case, an intelligent curiosity will be roused as to the nature of the new national pharmaceutical text-book of a neighbouring country, in which the art of pharmacy has been so successfully cultivated, and we hope to be able to meet this by devoting a short series of articles to a summary of the book, the first of which will be found on another page. As compared with Germany or the United States, it cannot be said that France, any more than our own country, is troubled by excess of restlessness or enterprise in those who are the arbiters as to the time when a revision of the Pharmacopœia becomes necessary. It appears that the present is only the fourth edition of the work published under the authority of a law that dates so far back as 1803. The first edition was published in 1818, the second in 1837, and the third,—that which now becomes obsolete,—in 1866, one year before the present edition of the British Pharmacopœia appeared. There is evidence, however, that in France, the fact is at last recognized that such intervals are too long and too irregular; for in the report upon which the decree for the present revision is based, it is expressly stated that the consequences have been "grievous." It is pointed out that a publication of this nature is essentially progressive: "the incessant study of the therapeutic properties of various substances, simple or "compound; the researches of naturalists and the "labours of chemists furnish every day new agents "or allow of the perfecting of preparations already "known; hence the necessity for revising this "work at predetermined periods."

In respect to one subject, the constitution of the body to be entrusted with the revision of a national Pharmacopœia, the appearance of the Codex is most opportune, coming as it does just at the time when the pharmacists of this country are meditating to approach Parliament with a view of obtaining a coordinate position with medical practitioners in the Pharmacopœia Committee. It appears that according to the "loi de germinal an XI.," which strictly speaking should regulate the preparation of the Codex, it is provided that the Commission should be composed of Professors of the Faculty of Medicine and Professors of the School of Pharmacy; but in consequence of a report presented to King LOUIS PHILIPPE on the subject of the appointment of a Codex Commission in 1836, it was decided that "in order to increase the guarantees of knowledge and authority" the professors nominated to serve upon it should be selected from among the members of the Academy of Medicine. This arrangement was continued in the Commission that prepared the Codex of 1866, and the precedent thus established, might have been maintained in its successor. But the Ministers of Public Instruction and Fine Arts and of Agriculture and Commerce, in the report upon which the decree for the preparation of the present edition was based, expressly urged that this constitution of the Commission would be too restrictive and that in conforming to it too rigorously there would be a risk of losing the assistance of *savants* of considerable authority. It was also pointed out that the Commission of 1861 had been completed by the addition of a certain number of members of the Society of Pharmacy, with *voix consultative*, and it was recommended that a similar course should be then taken so that the pharmaciens of France should receive every desirable satisfaction. The Commission as eventually appointed consisted of the Medical Inspector-General (M. GAVARRET), who presided; the Director of the Paris School of Pharmacy (M. CHATIN), who was Vice-President; two officials of the Department of Higher Education; six Professors of the Paris Faculty of Medicine (MM. BAILLON, BOUCHARDAT, HAYEM, REGNAULD, GERMAIN SÉE and VULPIAN); six Professors of the Paris School of Pharmacy (MM. BAUDRIMONT, BOUIS, BOURGOIN, A. MILNE-EDWARDS, PLANCHON and RICHE); and six members of the Paris Society of Pharmacy (MM. BLONDEAU, who acted as Assistant Secretary, DUROZIEZ, JUNGFLEISCH, MARTY, SCHAEUFFELE and VIGIER). It needs but a glance at this list to perceive how fully it is in accord with the position taken up by the pharmacists of this country; for in it not only are the names of pharmacists associated, as such, in honourable fellowship with those of members of the medical profession, but even among the representatives of the medical faculty itself are to be noticed the names of men upon whom pharmacy has as at least an equal claim with medicine. Indeed, those who were privileged to attend the International Pharmaceutical Congress in London in 1881 will remember that M. PETIT, speaking of this Commission, stated that the greater part of the work was being done by the pharmacists belonging to it, the medical men rarely attending the sittings. Moreover, the Society of Pharmacy, among whose ranks so many members of the Commission were found, found itself in a position to render assistance without any loss of dignity. It promptly divided itself into twenty-four sub-committees, each charged to report upon a special subject; the reports were afterwards discussed in general meetings of the Society and the results were communicated to the Commission. In the Preface to the new work the value of these communications is acknowledged in flattering terms. It is worth mentioning also that there is every probability that in future this arrangement for profiting in France by the services of practical pharmacists will have a legal basis, since the Bill now before the French Legislature, as left by the Committee to which it was referred, provides for the presence on the Codex Commission of an equal number of professors in medical schools, professors in pharmaceutical schools and pharmacists engaged in practical pharmacy.

As it is proposed to review this work in a more detailed manner in another place it will not be necessary to enter into a close description of it here. It will suffice to say that considering the pertinacity and ability with which the idea of a Universal Pharmacopœia has been advocated by our *confrères* across the Channel this latest official pharmaceutical text-book of their own appears, upon a somewhat superficial examination, to show very little additional approximation towards the Pharmacopœias of other nations. The Codex remains—the Codex, with most of its known peculiarities and, may we say it, defects. An effort has been made to avoid the chaos involved in the previous edition by the scattering of eight or nine hundred articles through seventy-five chapters. But this is only a relative success and we venture to predict that for a long time to come the index will be the most frequently consulted portion of the work. The old form of nomenclature has been maintained, and this combined with an alphabetical arrangement brings together all the salts containing the same acid radical, a result which is, in our opinion, at least inconvenient in its consequences, since the salts of the same base,—quinine for instance,—are thus distributed at intervals through the whole section. Such points as these seem to be open to general criticism; but when we turn to the materia medica and the preparations we freely admit that the judgment of French experts as to the constitution of the French Codex is indisputable, and we shall be quite prepared to find that the pharmaceutical portion of the work is elaborated with the skill that has made French pharmacy famous.

THE ANNUAL DINNER.

A MEETING for making preliminary arrangements for this annual gathering was held at the Society's house on Wednesday last, and upwards of a hundred gentlemen having expressed their willingness to become Stewards, it was resolved that the Thirteenth Annual Dinner of the Members of the Society and their friends should be held on Tuesday, May 20, at the Holborn Restaurant, and that the price of each ticket should be one guinea. The tickets are to be obtained from the Honorary Secretary only.

The extra expenses of the dinner will be met by the Stewards, as last year, and as it is therefore desirable that that body should be not only representative, but as numerous as possible, it has been decided not to close the list of Stewards for publication until Wednesday, April 2.

A Committee, consisting of the President, the Vice-President, the Treasurer, Professor ATTFIELD, Dr. PAUL, and Messrs. FREDERICK BARRON, ISAIAH BOURDAS, E. NORTHWAY BUTT, THOMAS GREENISH, and WALTER HILLS, was appointed by the meeting and requested to make the necessary detailed arrangements. Mr. RICHARD BREMRIDGE was appointed Honorary Secretary to the Committee, and all communications respecting the dinner should be addressed to him, at 17, Bloomsbury Square.

An Evening Meeting of the North British Branch of the Pharmaceutical Society of Great Britain will be held on Wednesday next, in the Society's Rooms, 119A, George Street, Edinburgh, when a paper will be read on "Tincture of Hyoscyamus," by Mr. W. Gilmour, and two papers on "Spiritus Ætheris Nitrosi:" I. "Composition in Relation to Deterioration," by Mr. P. MacEwan; II. "Characters and Tests," by Mr. D. B. Dott.

* * *

From an official Statement of the Trade of British India that has just been issued it appears that the export trade in drugs of this dependency has doubled during the last five years, amounting in the year ending March 30, 1883, to about £130,000. As might be expected, the increase is due to the development in the trade in cinchona bark, which now represents about two-thirds of the total exports. During the last year the quantity of bark exported reached 641,608 lbs., whilst seven years previously it only amounted to 72,452 lbs. Madras contributed most largely to swell the exports, the cultivation of cinchona in that presidency being more extensively carried on in private estates than in Bengal, where the principal cinchona estates are the property of the Government, which reserves a large proportion of the bark produced for local alkaloid manufacture. Most of the bark hitherto exported has come to London, but the demand from Italy for Indian bark is increasing. The total out-turn of cinchona bark from the Government plantations in India during the year 1882-3 was 527,199 lbs. In Sikkim these plantations cover 2294 acres and contain upwards of five million plants. The Nilgiri plantations cover 847 acres and contain about a million plants. The private plantations in Sikkim are estimated to extend over 331 acres and possess over six hundred thousand plants. In the Nilgiris cinchona is cultivated in combination with coffee on private estates, but no returns exist as to the extent. In Coorg also there are more than a thousand acres under cultivation, containing another million plants.

* * *

The local manufacture of alkaloid, referred to in the previous paragraph, appears to be affecting seriously the import of quinine from Europe into India, as last year it fell to 7585 lbs. from 10,615 lbs. in the previous year. As matters now stand, it is officially stated in this report that imports of quinine on account of the Government have already practically ceased, and an opinion is expressed that in course of time quinine will be no longer imported into India, since that country will be able to supply all her own wants from the plantations of Darjeeling and the Nilgiris.

* * *

We learn from this same report that lac dye, once an important item in Indian trade, is disappearing from the exports, under the influence of the competition of other dyes. Lac is exported chiefly as shell-lac, and to a smaller extent as button-lack. Stick-lack, which is the unmanufactured form of lac, is now hardly exported. Another dyeing material, safflower, the cultivation of which once constituted an industry of some importance in Bengal, has also been almost driven out of the field by the competitors that have been pitted against it by modern science.

* * *

It would appear, however, that the chemical dyes are not everywhere to have all their own way, since the Government of Persia has issued a decree prohibiting the importation of aniline dyes into that country, on the ground that they have been found to exercise an injurious effect upon the textile industries. It is believed that if this prohibition be strictly enforced, Persian carpets will recover their former reputation in the European markets for durability of colour.

* * *

In a report from Mr. Consul Mansfield, of Caracas, on the mining districts of Venezuela, he states that the *Dipterix odorata*, which yields the fragrant seed commonly known as the tonquin bean, abounds in the forests of the Caracas district, where the trees grow to a considerable size. The first crop of "beans" is yielded in the third year of the plant, the fruit bearing some resemblance to a small mango, and containing in its centre the "bean," which emits a powerful odour. A full crop is not yielded until two years later. The tree is said to grow in any climate in Venezuela, but to attain a greater perfection in warm temperate zones, alike removed from parching heat or the sharp mountain breezes. Last year's crop was a large one; Venezuela alone exporting five thousand quintals at an average price of 3½ francs per pound. It is estimated that the bean is used for curing and flavouring eight million quintals annually of tobacco exported from the United States. The vanilla also grows wild in many of the forests of Guayana. It may be remembered that a sample of Guayana vanilla was mentioned as having been shown at the Vienna exhibition last year.

In the course of a lecture on "Science and Singing," delivered by Mr. Lennox Browne, F.R.C.S., at the last meeting of the Society for the Encouragement of the Fine Arts, reference was made to the statements that have been published in respect to a means for improving the voice by the use of a mixture containing peroxide of hydrogen and ammonia, which is said to produce artificially the effects of Italian air. Mr. Browne stated that even if peroxide of hydrogen were capable of producing the alleged wonderful effect upon the voice, he had failed to detect by delicate chemical tests the presence of that compound in a sample of the mixture obtained direct from the inventor, and that although the mixture contained a quantity of free ammonia, and that gas is capable of acting as a temporary stimulant, in his opinion such an effect would be followed by relaxation, which was likely to cause injury to the voice. He also added that this opinion, based upon physiological and therapeutical experience, had been confirmed by actual experiments upon vocalists.

* * *

In the Fourth Annual Report of the State Board of Health, Lunacy and Charity of Massachusetts, the body whose proceedings have recently disturbed the wholesale druggists of Boston, a considerable prominence is given to the subject of the adulteration of food and drugs. In an appendix extending over nearly a hundred pages, Professor Sharples discusses the general subject, and incidentally expresses the opinion that outside the single article of milk injurious adulteration is by no means common, and that fraudulent adulteration is but little more so. It may be mentioned that the Massachusetts Adulteration Act authorizes this Board to spend annually a sum not exceeding three thousand dollars in carrying out its provisions, two-fifths of which is to be spent in the enforcement of the law against the adulteration of milk.

* * *

Some time ago we mentioned that, in compliance with a request from the Planters' Association, the Government of Ceylon had given permission that prescriptions might be made up for Europeans at the hospitals and dispensaries connected with the Medical Aid Ordinance, on the payment of a fee covering the cost. Some little friction, however, appears to attend the carrying out of this permission, since the dispensers at these Government establishments refuse to recognize as a prescription any document not bearing the signature of a medical practitioner, whilst the planters contend that the permission should be construed to include private recipes.

* * *

It may interest some of our readers in the North to learn that a "Revised Edition" of the List of Prices recommended by the Committee of the Midland Counties Chemists and Druggists' Association has just been issued. We presume that copies may be obtained from Mr. C. Thompson, the Honorary Secretary of the Association, Birmingham.

* * *

At the next meeting of the Chemical Society, on Thursday, the 20th inst., there will be a ballot for the election of Fellows. The papers announced are, "Note on the Preparation of Marsh Gas," by Messrs. Gladstone and Tribe; and "On the Action of Dibrom-α-Napthol upon Amines," by Mr. R. Meldola.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

On Wednesday, the 5th inst., the monthly meeting of the Council was held at three o'clock.

Present—The President, Mr. James E. Brunker, M.A., in the chair; Mr. H. N. Draper, F.C.S. (Vice-President); Drs. Collins and Montgomery; Messrs. John Evans, Grindley, Hayes, Hodgson, Simpson, Professor Tichborne and Mr. Wells.

The minutes of the last meeting were read and confirmed.

A letter was read from Mr. William J. Smyth, of 14, Newington Street, Belfast, asking whether he would be admitted to examination.

The President said Mr. Smyth applied to be admitted at the last examination, but the Certificate Committee did not feel at liberty to pass his certificate, because he had served in an establishment analogous to that of Mr. Hardy. The decision, however, which had since been arrived at in the case of Mr. Hardy covered that of Mr. W. C. Dobbin, who had signed Mr. Smyth's certificate; so that the reply to be given to Mr. Smyth was that he would be allowed to come in at the next examination.

On the motion of Mr. Hayes, seconded by Mr. John Evans, it was resolved that Mr. Smyth be informed that he may present himself at the next examination.

A letter was read from Dr. R. Crossitt, of Cookstown, county of Tyrone, asking whether the matriculation examination of the Queen's College, Belfast, which a Mr. Craig had passed, would be accepted in lieu of the Preliminary examination of the Pharmaceutical Society.

The President: The Registrar having made inquiries has found that this examination is accepted by the General Medical Council, therefore we must accept it under our bye-law.

The Registrar was directed to write to Dr. Crossitt accordingly.

A letter was received from Mr. James N. Hardy, defending the course of action which he had taken relative to opening a compounding department in the house of Beater and Co.

On the motion of Dr. Montgomery, seconded by Mr. Simpson, the letter was directed to be marked "read."

Dr. Montgomery moved, pursuant to notice, that the duties of the Visitors at the examinations should be defined. His object was to elicit the opinions of the members of the Council as to whether the Visitors should not take a more active part than they had hitherto done at the examinations. Should they act as the assessors who assisted in other examining bodies and give their opinions on any complications that arose? In the Apothecaries' Hall examination the assessor was present at the entire of it, and when it was over he took part with the examiners in deciding what the marks were to be. He did not mean to offer any positive proposal now.

The President: Would not the best course be to refer the subject to the Committee of Examinations for them to report on it? I think the introduction of something in the shape of an assessor would be very useful.

Mr. Grindley: Does the President of the English Society take part in the examinations?

The President: The President and another member of the Council of the English Society are always present at the examinations as well as the Inspector of the Board of Trade, who is assessor. The Lord Lieutenant has power to appoint a similar officer in this country but he has never done so. It might be well for the Committee to consider whether an application should not be made to the Lord Lieutenant on the subject.

The Vice-President said there were other matters also in respect of which he was sorry that their practice had not been assimilated to that of the English Society.

Mr. Grindley: Does the President of the English Society interfere in the examinations there?

The President: I cannot say that he interferes in the examinations, but he is always present at them.

Dr. Montgomery moved that the Visitors of the Examinations be requested to report on the question of the visitation of the examinations, and to suggest what the functions of the Visitors should be.

Mr. Evans seconded the motion, which was agreed to.

The Registrar read a report from the Pharmacy Act Amendment Committee, containing a *résumé* of the proposed amendments and the reasons for them.

Mr. Grindley said there was a rule that reports of Committees should be on the table for a month before they were discussed. This report involved vital changes, and it should not be sent forward to the Chief Secretary as representing the opinions of the entire Society without full consideration.

The President said he thought the Council would be quite in order in considering this report now. There was really nothing in these recommendations that had not received the sanction of the Council already. The report was simply a document for the information of the Chief Secretary, based on the opinions already expressed by the Council.

Professor Tichborne said they would be quite in order in considering the report now. What Mr. Grindley wanted was to have the recommendations carefully considered, and the best way of securing that would be to order the report to be printed and distributed amongst the members, and then it could be considered at the next meeting.

Mr. Hayes: Has not this matter been thoroughly threshed out already? I do not see why we should postpone it now.

The President said it was in the power of the Council to postpone the discussion of the report, but it was very important that the recommendations should be in the hands of the Chief Secretary as soon as possible. They would have to go into the hands of the Government draftsman; and it would perhaps be August before a Bill would be in shape. The English Bill was at present in the hands of the Government, and might be read any day. The Chief Secretary had said that if it were not opposed it might be taken up at once. It was very desirable that Parliament should deal with the two Bills at the same time.

Mr. Grindley said a matter which dealt with the rights and privileges of the members and licentiates of the Society ought not to be rushed forward.

The President: It has been under consideration for the last four years.

Mr. Grindley moved that the report be printed and circulated amongst the members of the Council, and that the consideration of it be taken up at the next stated meeting of the Council.

Mr. Wells seconded the motion, which was agreed to.

A report of the Committee on the supply of the Journal to the members of the Society was read.

On the motion of Mr. Hodgson, seconded by Dr. Collins, it was resolved to request the Pharmaceutical Society of Great Britain to supply the Journal to the present members of the Society for an annual payment of £20.

A report was read from the Law Committee in reference to a letter which had been referred to them from Mr. Robert J. Downes, suggesting alterations in the byelaws of the Society. The report stated that some of the suggestions were unsuitable, and that the rest had been already dealt with.

On the motion of Mr. Hodgson, seconded by Mr. Grindley, the report was adopted.

Mr. Cornelius Mannin, 2, Great Brunswick Street, Dublin, was elected a member of the Society.

Some accounts were ordered to be paid, after which the Council adjourned.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The ninth general meeting of the thirty-fifth session was held at the Royal Institution, February 14, 1884. Mr. Edward Davies, President, in the chair.

The minutes of the previous meeting were read and confirmed and the following donations to the Library and Museum were announced:—'The Transactions of the Literary and Philosophical Society of Liverpool,' for years 1880 to 1883, from the Society.

Mr. Lorne J. M. Campbell was then unanimously elected as member.

Dr. Symes stated that Drs. Cook and Watkins, of Bay View Asylum, Baltimore, had reported in the *Medical News* that, while treating a number of malarial cases and testing the urine of the patients daily, they had been surprised to find that, on the addition of picric acid, in each case a flocculent precipitate was formed, which could readily be mistaken for albumen. The patients were taking either quinine or cinchonidine, and it was found on experiment, that sufficient of the alkaloid passed through the system unchanged to bring about the result. Dr. Symes said picric acid was a very popular test with medical men in this country, notwithstanding that greater precautions were necessary in using it, than the old test, nitric acid. For example, it had been shown by Dr. Batten (*Lancet*, Nov. 11, 1882) that any excess of albuminous urine redissolved the precipitates and also that potash salts present would cause a precipitate. His chief object in bringing the matter forward was to show that most of the difficulties connected with the use of picric acid as a test for albumen in urine could be surmounted by observing two points, viz.:—always to use an excess of the reagent, and always to apply heat. He had pointed out, on a previous occasion, the necessity for the urine being decidedly acid. Dr. Symes's remarks were accompanied by experiments demonstrating these facts.

Mr. A. C. Abraham said that the writer to whom Dr. Symes had referred had evidently paid very little attention to the details of this test as devised by the originator, Dr. Johnson, who most emphatically insisted upon the necessity of boiling after the addition of the picric acid solutions. In his (Mr. Abraham's) experience, the addition of citric acid was in some cases also necessary, when the urine was not decidedly acid, although Dr. Johnson did not recommend this, unless the sample was neutral or lkaline.

The discussion on this subject was continued by Mr. Davies and Mr. Ward, and Dr. Symes was thanked for drawing attention to it.

Mr. Richard Parkinson mentioned that on taking into use a fourteen pounds parcel of powdered African ginger, which had been some time in stock, he noticed that the paper was much stained with some substance of the nature of a resin and desired to know the cause.

Mr. Conroy, in reply, stated that African ginger contained a much greater proportion of oleoresin than the Cochin or Jamaica varieties and this had possibly caused the appearance on the wrapper alluded to, though it was more probably due to the addition of oil during grinding. African ginger was the kind usually selected for manufacture of gingerine.

The President then called on Mr. M. Conroy, F.C.S., to read some "Notes on some New American Drugs and their Nature and Properties."

The specimens shown and described were twelve in number as follows:—

Stillingia.—Root of *Stillingia sylvatica* (queen's root, queen's delight, yaw root): nat. ord. *Euphorbiaceæ.* This root possesses a peculiar, unpleasant odour, and a bitter, acrid, pungent taste. In large doses it is emetic and cathartic, in small doses alterative. It is coming into demand in this country, and is said to be a very valuable agent in the treatment of syphilitic affections. The preparation most in demandis the fluid extract.

Leptandra.—Rhizome and rootlets of *Leptandra Virginica* (Culver's root, black root, physic root): nat. ord. *Scrophulariaceæ.* The odour is feeble and not disagreeable; the taste bitter, somewhat nauseous and acrid. The freshly gathered root is said to act violently as a cathartic. In the dried state it is much milder. Used in the United States as a laxative and tonic in bilious complaints. The eclectic practitioners consider it an excellent cholagogue, and use both the impure resin, which they call "leptandrin," and the root itself as a substitute for mercurials.

Castanea.—The leaves of *Castanea vesca* (chestnut): nat. ord. *Cupuliferæ.* Used in the treatment of whooping cough, but their therapeutic value seems to be much disputed. The leaves possess a slight odour and a somewhat astringent taste.

Gossypii Radicis Cortex.—The bark of the root of *Gossypium herbaceum*, and other species of *Gossypium* (cotton plant root): nat. ord. *Malvaceæ.* Dr. Bouchelle, of Mississippi, considers it to be an excellent emmenagogue, and not inferior to ergot in promoting uterine contraction. Dr. T. J. Shaw, Tennessee, thinks it superior in the treatment of amenorrhœa to any other emmenagogue, and equal to ergot as a parturient, while attended with less danger.

Viburnum. — The bark of *Viburnum prunifolium* (black haw): nat. ord. *Caprifoliaceæ.* Taste, slightly astringent and bitter; odourless. Said to be valuable in diarrhœa and dysentery. Recommended also in nervous disorders of pregnancy, and as peculiarly efficacious in preventing miscarriage.

Euonymus.—The bark of *Euonymus atropurpureus* (Wahoo, arrow wood, etc.): nat. ord. *Celastraceæ.* Said to be useful in intermittents, dyspepsia, torpid liver, constipation and dropsy; but on the whole the character of its action is said to be uncertain.

Grindelia.—The leaves and flowering tops of *Grindelia robusta* (hardy *Grindelia*, rosin weed): nat. ord. *Compositæ.* *Grindelia* has a balsamic odour, and a pungently aromatic and bitter taste. In America it is much used in the treatment of asthma, whooping cough and bronchitis, and in the former disease it has acquired great repute.

Chimaphila.—The leaves of *Chimaphila umbellata* (pipsissewa, prince's pine, wintergreen): nat. ord. *Ericaceæ.* The taste of the leaves is pleasantly bitter, astringent and sweetish. They are diuretic, tonic and astringent, and were employed by the American Indians in various complaints, especially scrofula, rheumatism and nephritic affections. It is now used in the treatment of dropsy.

Cimicifuga.—The rhizome and rootlets of *Cimicifuga racemosa* (black snake root, black cohosh): nat. ord. *Ranunculaceæ.* Said to be very useful in rheumatism, also in lumbago, sciatica, etc. Better known in England as *Actæa racemosa.*

Cypripedium.—The rhizome and rootlets of *Cypripedium parviflorum* (ladies' slipper, moccasin root); nat. ord. *Orchidaceæ.* The odour is heavy and unpleasant, and the taste sweetish, pungent and bitter. Used as a gentle nervous stimulant or antispasmodic. It has been used for the same purposes as valerian, but is said to be less powerful. Said to be useful in epilepsy.

Rhamnus Purshiana (*Cascara sagrada*), nat. ord. *Rhamnaceæ.*—The demand for this bark and its preparations has lately been considerable in this country. It is said to possess tonic laxative properties. Cathartic in large doses; stomachic and tonic in small.

Xanthoxylum.—The barks of *Xanthoxylum fraxineum* and *Xanthoxylum Carolinianum* are official in the U. S. Pharmacopœia under this title. Nearly inodorous, bitter, and very pungent.

Xanthoxylum is stimulant, producing when swallowed a sense of heat in the stomach with more or less arterial excitement. It is said to resemble mezereon and guaiacum in its remedial action. As a remedy in chronic rheumatism it enjoys considerable reputation in America. The bark used as a masticatory is a popular remedy for toothache.

Mr. Conroy described the nature and properties of each specimen and its medical and therapeutical uses, and in conclusion said that the specimens were collected by Messrs. Evans, Sons and Co., who requested him to offer them to the Association as a gift to its museum.

Mr. R. Parkinson said he had much pleasure in moving a vote of thanks to Mr. Conroy for his interesting paper, and also to Messrs. Evans for the gift of the specimens.

Mr. A. C. Abraham seconded the motion, and made some remarks on one or two of the specimens.

The discussion was continued by Dr. Symes, Messrs. J. S. Ward, A. H. Samuel and Davies, and the motion on being put was carried unanimously. Mr. Conroy having briefly replied, the meeting terminated.

ABERDEEN CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

At the weekly meeting of this Association, held on Friday, the 7th inst., in the Café, Aberdeen, the President, in the name of the Association, presented Mr. G. D. Bowie, Secretary of the Association, who is leaving to fill a situation in Stonehaven, with an address expressing appreciation of the services rendered to the Association in his capacity of Secretary, and also of his general character and ability.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The ninth meeting of the present session was held in the Pharmaceutical Society's rooms, 119A, George Street, on Thursday evening, February 28, at 9.15, Mr. C. F. Henry in the chair.

The minutes of the former meeting were read and confirmed, after which Mr. Peter Boa read a paper on "The Cultivation of Taste in the Practice of Pharmacy." In introducing the subject the essayist showed that the pharmacist is generally looked upon by the public as a man of taste. This he held to be due primarily to the fact that pharmacies as a rule are neatly furnished and have a air of refinement. But, although the environments of the pharmacist may show good taste, it is quite possible that this may be due to the skill of the cabinet maker, by whose judgment he has been guided. The true indication of good taste on the part of the pharmacist is found in the manner in which he finishes his work; he may be scientifically accurate in his manipulations, but if he send out slovenly done-up parcels, written directions, etc., he puts before his customer causes for reflection and mistrust. In fact, a patient cannot judge of the contents of a bottle; but if it be delivered to him in a condition which shows that care and good taste have been exercised in finishing it off, he judges that equal care has been exercised in the professional part of the transaction. The essayist, therefore, held that in pharmacy, cultivation of taste should begin with pupilage, and if the pupil be trained to perform well those parts of his work upon which the public sums its judgment, he is brought into a groove which leads him to exercise accuracy and good taste in the purely pharmaceutical part. The essayist then expressed his thoughts on the selection and use of corks, labels, paper, twine, sealing wax and address stamps, and placed on the table several examples of gross violation of good taste on the part of pharmacists, in that department.

The essay was well received by a large audience, and on the motion of the President, seconded by Mr. MacEwan, a hearty vote of thanks was awarded to Mr. Boa.

A long and animated discussion followed, in which Messrs. Crowden, Duncan, Hill, Robertson, Simpson, Turnbull, and others took part, Owing to the lateness of the hour, the other business was delayed until the next meeting, which was held on Wednesday, March 5.

At this meeting, Mr. Boa presided, and after the minutes of the former meeting had been read and confirmed, Mr. J. B. Dunlop read a paper on "Pharmacopœial Natural History," in the course of which he gave a very interesting account of the various animal substances of materia medica, a special feature of the paper being a series of artistic drawings executed by Mr. Jardine, an apprentice member of the Association. The paper was further illustrated by typical specimens of the drugs treated of. A vote of thanks was awarded to Mr. Dunlop, and a discussion followed in which several members took part.

Mr. A. H. Simpson then introduced a proposed resolution that the papers read before the Association should be printed at the end of each session, and moved that the Committee of the Association should be instructed to consider the matter in its details, and report. The motion was seconded by Mr. Hill and agreed to.

After several queries had been replied to, notice of others was given for next meeting, which will be held on March 26, when Mr. W. S. Turnbull will read a paper on "Elementary Botany," intended for the guidance of those preparing for examinations.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on March 6. Dr. W. H. Perkin, F.R.S., President, in the chair.

It was announced that a ballot for the election of Fellows would take place at the next meeting of the Society (March 20).

The following certificates were read for the first time:—Messrs. G. C. Bose, J. P. Battershall, W. D. Crumbie, W. J. Grey, H. G. Greenish, J. H. Wainwright.

Dr. Miller then read a paper, entitled—

Studies on Sulphonic Acids. No. I. *On the Hydrolysis of Sulphonic Acids, and on the Recovery of Benzenes from their Sulphonic Acids.* By H. E. Armstrong and A. K. Miller. The authors were led investigate the behaviour of sulphonic acids on distillation with sulphuric acid, in the course of a study of the hydrocarbons resulting from the action of dehydrating agents upon camphor, their primary object being the separation of the 1:2:3:5 tetramethylbenzene. It appeared, from various considerations, probable that this body would form a highly unstable sulphonic acid. It was found on passing steam into the sulphuric acid solution of the mixtures of hydrocarbons from camphor that all the benzenes could in this way be recovered. The method consists in passing steam through the solution of sulphonic acid or sulphonate in sulphuric acid, the acid solution being heated and mainmained at the temperature at which hydrolysis takes place with fair rapidity. A weight of acid was usually employed equal to that of the sulphonate taken. Apparently no decomposition of any of the benzenes takes place, and the yield of hydrocarbon may be said to be theoretical. The authors give the following list of sulphonic acids used, and the temperature of initial hydrolysis:—Benzensulphonic acid, 175°; toluenparasulphonic acid, 150°; metaxylensulphonic acid, 120°; orthoxylensulphonic acid, 120°; paraxylensulphonic acid, 120°; pseudocumene sulphonic acid, 115°; mesitylensulphonic acid, 100°; cymensulphonic, 130°; 1:2:3:5 tetramethylbenzensulphonic acid, 120°; metamethylisopropylbenzensulphonic acid, 120°; 1:2:4 dimethylethylbenzensulphonicacid, 120°. From their results the authors believe that it will be possible to separate many hydrocarbons by this "fractional hydrolysis" from mixtures of their sulphonic acids. The authors give some results in which the rate of hydrolysis at different temperatures has been studied. They are about to investigate the influence of pressure on the rate of hydrolysis.

Dr. Tilden asked if there appeared to be any relation between the composition of the sulphonic acids and the temperatures at which they were decomposed,

Dr. Armstrong said that sufficient data had not yet been obtained, but apparently the simpler the constitution the less readily did decomposition take place. He also mentioned that in many cases fractional distillation completely failed as a method for purifying hydrocarbons, principally because bodies belonging to different series, but having the same boiling point, were often present in the same mixture. By the above method this difficulty might be overcome. The excess of hot strong sulphuric acid was also advantageous in carbonizing some hydrocarbons present as impurities.

The Secretary then read a paper—

On a Relation between the Critical Temperatures of Bodies and their Thermal Expansions as Liquids. By T. E. Thorpe and A. W. Rücker.—From Van der Waals' investigations it appears that the want of similarity between the formulæ which express the expansions of liquids is due to the fact that their initial point is, in general, the arbitrarily-selected temperature of melting ice; uniformity of mathematical expression can only be attained, if, in each case, the temperature is expressed, not in ordinary thermometric degrees, but as a fraction of the absolute boiling point of the substance. It is thus possible to obtain the law of the thermal expansion of any one liquid from that of any other, if their critical temperatures be known. Mendelejeff, in a paper recently read before the Chemical Society, gave an extremely simple and accurate empirical formula for the expansion of liquids. One of the conclusions at which Van der Waals arrives is that the product of the coefficient of expansion under constant pressure into the absolute critical temperature is, at corresponding temperatures, the same for all bodies. By combining these two formulæ the authors arrive at a formula, which may be expressed in words as follows:—The density of a liquid is proportional to the number obtained by subtracting its absolute temperature from its absolute critical temperature, multiplied by a constant which is the same for all substances. The values of this constant in the case of the substances for which the necessary experimental data exist are almost identical, and approach very closely; therefore the above expression can be further simplified thus: The density of a liquid is very nearly proportional to the number obtained by subtracting its absolute temperature from twice its absolute critical temperature. If further investigation proves that the range of variations in the above constant is small, the expression already given affords a ready and valuable means of calculating the critical temperatures of bodies from observations on their expansions as liquids.

Dr. Hugo Müller then took the chair, while Dr. Perkin read a communication entitled—

Remarks on the Densities of Members of Homologous Series.—An investigation, in which the author has been for some time engaged, necessitated the determination of the densities of an extended series of carefully prepared products, especially the acids and ethers of the fatty series. On examining these results they exhibited a relationship to each other; the results were therefore plotted in curves, in which the numbers of carbon atoms were used as abscissæ, and a scale of numbers, embracing those of the densities, as ordinates. The curves so obtained are regular, and the dots representing the experimental numbers are either on or close to the curves, and it is obvious, from an inspection of the curves, that the densities of the homologous acids and ethers follow a regular law.

Dr. Tilden remarked that there were singular irregularities as regards the physical properties, for instance melting points, in some of the homologous series.

Dr. Armstrong suggested that in the case of formic and acetic acids this might be explained by supposing that the influence of the hydrocarbon portion of the acid was small compared to that of the oxatylic portion; and again we had no evidence to prove that the formula of acetic acid was not more complicated than $\left\{\begin{matrix} CH_3 \\ COOH. \end{matrix}\right.$ If a formula could be calculated for Dr. Perkin's curves it might be most valuable in discriminating isomeric acids.

Dr. Perkin said that as regards magnetic rotation formic and acetic acids, seemed to be outside the fatty acid series, which seemed to commence with propionic acid.

Mr. Farrington then read a—

Note on some Experiments made at the Munster Agricultural School to determine the value of Ensilage as a Milk and Butter-producing Food.—Two cows were fed for a week upon ensilage and five lbs. of meal, and for a second week upon a mixed food of carrots, beet, hay and oats. The total quantity of milk obtained with the ensilage was 433½ lbs., giving 1 lb. of butter from 33 of milk; with the ordinary food 414½ lbs. of milk yielding 1 lb. of butter to 34·5 from milk were obtained. The butter from the ensilage was inferior in quality. The author states that 84 lbs. of ensilage replaced 25 lbs. of hay, and that the expense of making hay and its equivalent of ensilage was equal, but that the use of ensilage effected a saving for each cow daily of two stone of roots and ¼ bushel of grains. The total solids and cream in the milk were estimated. In answer to some questions of Mr. Warington the author stated that he was unable to give the basis upon which the equivalent quantities of hay and ensilage were calculated, and did not know whether the grass was compounded of the same materials (grass, vetches, etc.) as the ensilage.

The Secretary then read a—

Note on the Behaviour (I.) *of the Nitrogen of Coal during Destructive Distillation; and* (II.) *a Comparison of the Amounts of Nitrogen left in Cokes of various Origin.* By Watson Smith. — Professor Foster, in a recent paper (*Chem. Soc. Jour. Trans.*, 1883, 110), states "I have not made any experiments on the amount of nitrogen in tar, nor am I in possession of any information on the subject. I have assumed that the quantity is relatively small." The author of the present paper has investigated the subject, having observed in 1868 that ammonia was frequently formed during the distillation of coal tar. He has obtained the following numbers: nitrogen in the tar 1·667 per cent.; in crude benzene from the tar 2·327; in "light oil" 2·186; in creasote oil 2·005; in "red oil" 2·194; in the pitch 1·595. The author has also estimated the amounts of nitrogen in three cokes, *a.* ordinary gas coke, *b.* Beehive metallurgical coke, *c.* a hard compact metallurgical coke from Simon Carve's oven. *a.* contained 1·375 per cent; *b.* 0·511; *c.* 0·384 per cent. of nftrogen.

Mr. E. W. Voelcker said, in some experiments which he had recently made, he had found that it was impossible to get rid of the whole of the nitrogen by carbonizing such bodies as peat, charcoal, etc., even when very high temperatures were used. These results seemed to have an important bearing on the analysis of nitrogenous bodies by the soda lime method; when manures from such substances as blood, fish guano, etc. were analysed, if any lumps formed the whole of the nitrogen could not be obtained.

Mr. Groves said that no statement was made as to where the coke came from, whether from the middle or sides of the oven. The middle portion of the coke being subjected to a much lower temperatures than the coke at the sides might be expected to contain more nitrogen.

On a Hitherto Unnoticed Constituent of Tobacco. By

T. J. Savery.—Whilst examining some tobacco for sugar, a substance was noticed in the aqueous solution which reduced Fehling's solution. This body was almost completely removed by clarification with subacetate of lead and the resulting liquid was free from sugar. The author succeeded in isolating this reducing substance by precipitation with subacetate of lead, decomposition with sulphuretted hydrogen, etc. The substance gave a green coloration with ferric chloride, changing to red on the addition of potash; with ferrous sulphate alone no change was produced, but when this reagent was added with ammonia, a dark brown colour appeared. A purer product from unmanufactured tobacco gave the same reactions and developed a red colour with strong sulphuric acid, changing to a claret on the addition of a trace of nitric acid. A green colour was produced with either potash or ammonia. The substance precipitated hydrochlorides of quinine and cinchonine. The author concludes that the body is closely allied to caffetannic acid and names it tabacotannic acid. No analyses are given.

The Society then adjourned to March 20, when a ballot for the election of Fellows will be held, and a "Note on the Preparation of Marsh Gas," by Dr. Gladstone and Mr. Tribe will be read.

Parliamentary and Law Proceedings.

The Dispening of Large Doses of Ergot.

An adjourned inquest, touching the death of a woman named Sarah Ballinger, was held on Monday last at Cheltenham, before Mr. Coren. The woman was living apart from her husband, and the proceedings at the inquest with respect to the dispensing of certain prescriptions may present points of interest to our readers.

Mr. Boughton, the medical practitioner who attended the deceased, being recalled, stated that he thought the deceased was suffering from a kind of fibroid tumour, which had been growing, he thought, for about three months. Such a tumour would not always leave traces when it came away. The reason he saw deceased three or four times a day during the last fortnight was because she was so much worse. She was very intermittent in her illness, and during the last week he thought the case was a very serious one. He thought about a week before her death that she would not recover. The applications he used were carbolic acid and Condy's fluid, and Dr. Kirkland used the latter. A fibroid tumour could be removed without an operation.

Mr. Hands, chemist, here, at the request of the Coroner, produced some prescriptions, and Mr. Boughton admitted the initials to them. The Coroner showed the witness one document, and asked if it was in his handwriting. Without examining it, Mr. Boughton said it was.

Mr. Boughton was then questioned as to the nature of the prescriptions.

The Coroner then pointed to a prescription, and asked the witness whether it could not be used for an unlawful purpose.

Witness: It could not, and certainly not in the dose there. It it a small dose.

Mr. Coren then asked the witness if he knew the Mrs. Roberts to whom the prescription was given?

Witness: No, I am sure I do not.

The Coroner: Do you know anyone named Roberts living at Bristol Road, Gloucester?

Witness: No.

The Coroner: You keep no books, and, therefore, cannot tell anything about it?

Witness: No, sir, I cannot. The doses were moderate.

Having cautioned the witness, Mr. Coren asked: Was that prescription not given for an unlawful purpose?

Witness: No, sir, decidedly not.

The Coroner: Would it have that effect?

Witness: No, sir, I do not think it would in that dose.

The Coroner: I think it is due to the chemist to say that he did not dispense that prescription, but gave something of a different character.

Mr. Heath: May I ask who that was?

The Coroner: Mr. Hunt, of Gloucester. I think it is only right I should state this, and I have a copy of the prescription made up by Mr. Hunt in lieu of that given by Mr. Boughton. Here are the two documents, and I merely make the explanation.

The witness's examination was then resumed. In reply to questions he said his practice was mostly amongst women and children. The prescription to Mrs. Roberts was given for a purely lawful purpose, and was not in excess of the dose permitted by the Pharmacopœia.

By Mr. Heath: It was quite possible that he should have given the prescription read to a Mrs. Roberts, whom he might have known nothing about. He had no remembrance of the woman calling herself Roberts for whom he wrote that prescription, and as a matter of practice he often gave prescriptions to persons whom he did not know before. He had had special practice in these cases, and might therefore give stronger prescriptions in this particular class of disease than other men might do; and this Mrs. Roberts might have been suffering from a tumour such as the deceased was suffering from. When deceased first came to him he was in some little doubt as to the exact nature of the complaint from which she was suffering. It took him a fortnight to discover what the exact tumour was, though he had the opinion all along that a formation would have to be removed. If the deceased had been pregnant when he first examined her, there would not have been the symptoms of which he had previously spoken. Dr. Kirkland was called in at the request of the relatives, who gave him the money to pay the fee. When the first prescription was made up he told the woman of the house to ask the dispenser to moderate the ingredients. He was attending another patient at the time at 2, Granville Street, and they both had a dose of the same medicine. In all the prescriptions he had followed the Pharmacopœia in such cases.

Mr. Clark: These prescriptions you gave seem to have been made up by no less than three separate chemists—Mr. Hands, Mr. Board, and Mr. Spiers—within a month.—Yes, they were.

Did you direct them to be taken to those various places?—I did.

For what reason?—I had no particular reason at all.

Is it usual for a medical man to write out his prescription, and in the space of one month to send to three different chemists?—Yes, if he likes.

In your particular line?—Yes.

In reply to a Juryman, witness said the dose given to Mrs. Ballinger was one-third less than that given in Mrs. Roberts's prescription.

Mr. William Hands, chemist, High Street, produced prescriptions dated the 31st of January and the 22nd of February. The first prescription was brought when he was out, but he dispensed it, altering it a little. He thought the dose of ergota too large, and he put half an ounce instead of two ounces as mentioned in the certificate.

The Coroner: Then in point of fact you put a fourth of the dose.

Witness replied that was so. He thought that Mr. Boughton had made a mistake, and he explained it to him afterwards. That was the only alteration he made. One was a simple tonic mixture, and was dispensed according to the prescription. He should like to remark that he had received dangerous prescriptions from other medical men in the town. For instance, he was once ordered to put 16 grains of strychnine in sixteen pills, and he had to consult the doctor before he did it.

The Coroner said there was no doubt medical men were liable to mistakes, as in the recent death at the Infirmary at Gloucester, where the patient died from an overdose.

The Coroner then asked the witness to examine the other prescriptions put in which were dispensed by other chemists. After examining them he said that he should not have dispensed one of them (the prescription given to Mrs. Roberts) without first asking Mr. Boughton.

The Coroner: Would you give me your opinion of that prescription?

Mr. Hands: I would rather not. There are medical men here, who would speak better than I can.

The Coroner: Of course I should not like to press you.

Mr. Hands: I do not know the nature of the case prescribed for.

The Coroner: I can ask you this, Would you dispense it?

Mr. Hands: No, sir. Not without consulting the medical man who wrote it.

A juryman (Mr. Gallop) asked the witness if the reason why he did not dispense the dose as originally prescribed was because it was a dangerous one.

Mr. Hands replied that he would rather not answer. It was a question for the medical men.

Another juryman (Mr. Smith): May we take it that as the witness refused to dispense in that quantity he considered it dangerous?

Mr. Hands: Well, it is not a usual dose.

Mr. Thomas Francis Board, chemist, High Street, identified two bottles containing medicines found in the bed room in which the deceased died as having been dispensed at his shop. He said he held no prescriptions from Mr. Boughton, but he remembered giving the larger bottle of mixture, and the small bottle of mixture produced, to Mr. Boughton. He made up the contents of the large bottle from verbal directions given to him by Mr. Boughton. It contained 40 grains of quinine, with a little acid to dissolve it. This made a powerful tonic, but there was nothing dangerous in it. The small bottle was also made up at the request of Mr. Boughton, and someone called afterwards for it. It contained a drachm of a preparation of opium, and was a usual dose.

Francis John Spiers, in reply to the Coroner, said he was not a chemist or a dispenser. He kept a chemist's shop in the High Street, which belonged to his father, who was a qualified dispenser. He had not passed any examination as dispenser, but he was reading for it. He served an apprenticeship with Mr. Gibbon, and was dispenser at the Dispensary. His father was responsible for the shop. He dispensed two of the prescriptions. (These were stated by the Coroner to be of an ordinary character.)

Mr. Edward Pearce Spiers, chemist, High Street, said that he dispensed prescription No. 1, but not as written. He was desired by the person who came for it to modify the dose. The prescription was for two ounces of liquid extract of ergota, and though he gave half the quantity, that which he gave was of the same strength as required by the prescription.

Dr. Kirkland, recalled, stated that he saw the deceased on the Sunday morning before her death. She was semiconscious. He asked the deceased if she had had a premature birth recently, and she said "No; four or five months ago." He believed the deceased was suffering from blood poisoning of an acute character. If the deceased had had what she said she had three or four months previously he should, under certain circumstances, have anticipated that the same symptoms would have been observed. That, in fact, was his diagnosis of the case, formed from the history given of it by Mr. Boughton. The latter said that he thought he had removed a tumour from the deceased, who was feverish afterwards, and he could not quite understand it. The fact that a tumour had been removed would not necessarily be observable in a *post-mortem* examination. A tumour would be treated by drugs, and ergota would probably be used. He attended the deceased on behalf of Mr. Arkell, a relative of the deceased. Having looked at the prescriptions, witness said that prescription No. 1 was a pharmaceutical dose, and so was No. 4, and there was nothing special about the other prescriptions given in the case. Ergota would be quite properly given for a fibroid tumour. Three of the ingredients in No. 6 (Mrs. Roberts's) were rather large doses, larger than he should give.

The witness was examined at great length on the medical aspect of the case. He stated in reply to the Coroner that the same means and the same medicines used in this case, to remove a supposed tumour, might have been effectual for another purpose. From the symptoms he thought himself that a premature birth had taken place, and it might have been recently, or three months ago.

At this stage the inquiry was adjourned.—*From the Cheltenham Examiner.*

Poisoning by "Naphthine."

The *Northern Whig* of Wednesday reports an inquest held in Belfast touching the death of Mrs. Mary Ann Thomson, the wife of Deputy Surgeon-General Thomson. According to the evidence Mrs. Thomson had conceived an unwarranted jealousy respecting her husband, which caused her to behave strangely, and on the previous Friday he came to the conclusion that she had taken poison. Medical assistance was obtained, but considerable difficulty was experienced in procuring a stomach pump that was in order. An emetic of mustard and water was in the meantime administered, but all the efforts to save the lady's life were futile, and Mrs. Thomson died about eleven o'clock. The *Northern Whig* goes on to say that it was ascertained at the inquest that deceased had partaken of chloral, and it further appeared that in the early part of last week she drove in a cab to the establishment of Messrs. Grattan and Co., Corn Market, and there purchased a quantity of naphthine (*sic*), the value which, together with a small hypodermic instrument for the purpose of injection, was £2. She produced a copy of a medical work, and said she wanted two bottles of the naphthine for a friend in India, and that it would require to be carefully packed in a box so that it might be conveyed to its destination in safety. It seems that the assistant in the shop, after some consultation with the manager, supplied the lady with the naphthine, without obtaining from her any signature, and that she thereupon drove off. On the night after Mrs. Thomson died, her husband and Dr. Arnold, on searching the bedroom, discovered in her wardrobe one of the two bottles in which she had received the naphthine, and subsequently found the box in which the bottles had been packed.

A good deal of discussion took place at the inquest as to the propriety of supplying such a large quantity of poisonous liquid to a stranger, and the Coroner considered it advisable to send for Mr. Yoxall, the manager of Messrs. Grattan's establishment in Corn Market. This gentleman, on his arrival, pointed out that the Act of Parliament did not require the seller to obtain signatures for this particular fluid.

The Coroner objected in very strong terms to such a large quantity of it being given to any person who was unknown to them, and said that, although the establishment of Messrs. Grattan, as they all admitted, was one of the finest and best conducted of the kind in the three kingdoms, yet they must be careful not to allow a repetition of such an occurrence.

After considerable discussion regarding the various features of the case, the Jury returned a verdict to the effect that Mrs. Thomson had committed suicide by partaking of poisonous fluids whilst in a state of unsound mind.

Fatal Dispensing Mistake.—Committal of an Assistant for Manslaughter.

An inquest was opened on Tuesday, the 4th inst., at Bristol, before Mr. H. S. Wasbrough, city coroner, into the circumstances attending the death of Eliza Vowles, a married woman, thirty-three years of age, whose death was alleged to have been caused by an ipecacuanha powder being made up for her by a chemist's assistant, instead of jalap powder. Several witnesses were examined, and the inquest was adjourned till Thursday, for a *post-mortem* examination to be made.

At the adjourned inquest on Thursday,

Mr. L. M. Griffiths said he had made a *post-mortem* examination of the body. He examined all the cavities of the body. There was considerable evidence in the chest of disease, some of which was of long standing. There was also evidence of serious disease of the bronchial tubes. There was considerable adhesions of the membrane covering the lungs, and of the lungs themselves. There was evidence in the upper part of the lungs of consumptive disease, but it was not active. The other organs were much congested, but otherwise healthy. He considered the congestion to be due to the opium. There was scarcely anything in the stomach. He attributed death to an overdose of opium, which acted with unusual force upon the deceased, who was a person in exceedingly weak health. Deceased was naturally a weak person and had been brought lower by the disease in the chest. The immediate cause of death was opium poisoning.

Mr. Keevill, chemist, said his assistant was a very careful man, and he had had considerable experience. At the time when Mr. Vowles came for the powders he (Mr. Keevill) was out of the shop; but he had since gone into the matter, and found that his assistant was going to make some compound ipecacuanha pills that same evening. When Mr. Vowles came for the powders he referred to the books, and found the prescription. Directly underneath Mrs. Vowles's prescription was one for ipecacuanha powders; it was of the same amount, and the price was also the same, and that was how his assistant came to make the mistake. Mr. Keevill produced the book in which the prescriptions were entered.

The Coroner, in summing up the case, said the question the jury would have to decide lay in a small compass. The chief point was whether due care was used by the assistant in dispensing the medicine. If they thought sufficient care was not used, then the assistant was guilty of culpable negligence. The deceased had suffered from consumption, for which jalap powders were prescribed. These did her good, and on Monday the husband went to the chemist for some of them, and instead of giving him compound jalap powders the assistant gave him compound ipecacuanha powders, which contained opium. One of these powders, when administered to the deceased, brought on drowsiness, and eventually the woman died from the effects of taking it. The deceased, having been suffering from consumption, was naturally weak; but it made no difference, however weak she might have been. If, through the carelessness of anyone, her life was shortened, then it was criminal negligence. He advised them to dismiss the case of consumption, for if the woman could not have lived long, yet through the carelessness of someone she died, then it amounted to the same thing; the law was quite clear upon that point. He quoted a case to explain the point, in which a woman sent to a chemist for a pennyworth of paregoric for a sick child. The message was properly delivered, but by the side of the bottle containing the paregoric was one containing laudanum. The apprentice, in mistake, took down the bottle of laudanum and gave it for the paregoric. It was taken home and some given to the child, who died from the effects of it. The apprentice in this case was committed for manslaughter. He thought that case and the present one were very similar. If they thought that when the jalap powders were sent for and ipecacuaha powders sent back, the assistant exercised due and ordinary care, he would be free from blame; if not, he was guilty of criminal negligence. It was most important to the public that all prescriptions should be dispensed accurately, because their lives were in the hands of dispensers.

After a short consultation the jury returned a verdict of "Gross negligence on the part of the assistant."

The Coroner: You know that amounts to manslaughter?

The Forman: Yes.

The assistant, who is a German, named Thomas Klomowski, was therefore committed for trial on a charge of manslaughter.

The case also came before the magistrates at the Police Court on a charge of manslaughter against Thomas Klomowski. After hearing the evidence, the chairman of the magistrates said they had carefully considered this case, and there was no doubt the defendant made a mistake in taking the prescription, which was not the one he should have taken. Death was accelerated by the medicine, but the bench could not see that there was any gross carelessness in the case. If this had been done with an utter absence of care they would consider it culpable, but care was taken, and this was an error. They did not think it was a case of manslaughter. The charge would be dismissed.

Obituary.

Notice has been received of the death of the following:—

On the 29th of January, Mr. Thomas Mills Nall, Pharmaceutical Chemist, Stanley Street, Leek, Staffordshire, Aged 63 years.

On the 8th of February, Mr. James Moore Crosby, Chemist and Druggist, Newborough Street, Scarborough. Aged 56 years.

On the 13th of February, Mr. Edwin Green, Chemist and Druggist, High Street, Market Harborough. Aged 35 years.

On the 18th of February, Mr. Henry Woolhouse Shaw, Pharmaceutical Chemist, Market Place, Doncaster. Aged 42 years. Mr. Shaw had been a Member of the Pharmaceutical Society since 1871.

On the 18th of February, Mr. Humphrey Wolferstan, Chemist and Druggist, Kirk White Street, Nottingham. Aged 68 years.

On the 22nd of February, Mr. William Francis Williams, Pharmaceutical Chemist, Beaufort Square, Chepstow. Aged 35 years.

Correspondence.

F. Walder.—Use carbolic acid in crystals, and a little stiff glycerine of tragacanth.

Jersey.—(1) Dissolve separately the ferri cit. c. quin. and potass. iodid.; with one of them put a half a drachm of mucilage for each ounce of the completed mixture, and mix. (2) Make the pills up with ol. theob. and ung. resinæ, say 18 grains of the former and 6 grains of the latter. If the operation be conducted quickly the pills will keep any time.

"*Spes*."—(1) Assistants who, being of full age at the time of the passing of the Pharmacy Act, furnished the Registrar before the 31st of December, 1868, with certificates that they had been engaged for a period of not less than three years in the dispensing and compounding of prescriptions as assistants to chemists and druggists. (2) Apply to the Secretary.

Communications, Letters, etc., have been received from Messrs. Beckett, Williams, Bennett, Granville, Inquirens, Associate.

THE MATERIA MEDICA OF THE NEW PHARMACOPÉE FRANÇAISE.

The list of articles of materia medica forms the first portion of the work (pp. 29–83) and is arranged alphabetically as in the last edition, the vernacular names being placed first and followed by the scientific names. As previously mentioned the chemical substances which formed a separate portion of the materia medica in the last edition are now arranged in the second part of the work, which is entitled 'Pharmacie Chimique,' so that in the new edition the materia medica includes only substances obtained from the animal and vegetable kingdoms. The list of these is still a large one, comprising four hundred and ten articles, of which one hundred and sixty-nine, indicated with an asterisk, are expected to be kept in stock in every pharmacy. In the last edition there were five hundred and thirty-five articles belonging to the vegetable and animal kingdoms, of which two hundred and six were marked with an asterisk.

In the preliminary chapter, in which directions are given concerning the collection and preparation of roots, leaves, flowers, etc., there is hardly any alteration. The term dicarpous (*dicarpiennes*) is introduced as synonymous with the term biennial. The very impractical direction to gather roots of perennial plants in the second or third year is still retained. Obviously it is next to impossible to ascertain whether such plants as tormentil, gentian, male fern, bistort, etc., are more than three years old, while the assertion that if older they are too woody and subject to diseases which alter their properties, is a somewhat sweeping one.

In this chapter also a note is added to the effect that the term root is often confounded with that of rhizome, and accordingly in several instances the term "rhizome" has been substituted in places where "racine" occurred in the last edition. The terms *rhizome*, *souche* (root-stock) and *racine* are, however, used with such a want of uniformity that it is difficult to understand what definition is applied by the authors to the respective terms.

The list of articles being such a large one, it will be more conveniently considered under the sections adopted in the work itself.

A.

The following are omitted:—Musk seed (abelmosch), the fruits of *Anacardium occidentale* (acajou) and *Semecarpus Anacardium* (anacarde oriental), *Alchemilla vulgaris*, *Anemone pratensis*, the bark of *Bowdichea virgilioides* (alcornoque), areca nuts, and the roots of *Aristochia Clematitis*, *A. longa*, *A. rotunda* and *A. cymbifolia.*

There is only one addition under "A," the entire plant of Arenaria rubra (*Spergularia rubra*), Pers. This is an introduction from Algeria, where it is used in cystitis, vesical catarrh, hæmaturia, jaundice, etc. The results obtained by Dr. Bourreau, in Paris, indicate that it possesses powerful diuretic properties, and is useful also in dysuria, gravel, nephritic colic, etc. M. F. Vigier, who analysed the plant, believed its properties to be due to the large amount of alkaline matter it contains, and to a resinous aromatic substance. Judging from the general properties of the family to which it belongs one would have expected it to contain a principle allied to saponine, but none was detected by M. Vigier. He found, however, that when distilled with water it gave an ammoniacal distillate (*Journ. de Pharm.*, [4], xxx., p. 371).

Alterations have been made under the following:—

Ache de Marais. *Apium graveolens*, L.—The authors appear to have been in doubt as to what to call the root of celery, the official portion being now described as "portion souterraine," instead of "racine," as in the last edition.

Aconit Napel.—The note directing that preparations of the leaf instead of those of the root should be always dispensed when the latter were not indicated in the prescription is now omitted, although both leaf and root are still official. No directions are given for distinguishing this root from the Japanese drug, nor for ascertaining its quality.

Agaric de Chene is now placed under the more familiar name of Amadou.

Alkékenge is now styled Alkékenge Coqueret.

Aloes.—Cape aloes is still the official species and the only one to be used unless directions to the contrary are given. *Aloe africana*, Mill., and *A. perfoliata*, L., are now mentioned as species yielding it, in addition to those mentioned in the last edition. Socotrine aloes is omitted, the following remark being made concerning it:—"Socotrine aloes, formerly the most esteemed of the African aloes, only comes into commerce casually." This is perfectly true; the aloes which arrives in this country and passes under the name of Socotrine aloes, is always of the hepatic character, or, if approaching Socotrine in colour and translucency, gives a crimson reaction with nitric acid, like that given by Barbadoes aloes (*A. vulgaris*, Lam.).

Amandes.—The botanical source is now given as *Prunus* (*Amygdalus*) *communis*, L., which is incorrect according to the generally accepted laws of botanical nomenclature, *Prunus communis* not being Linnæus' name for the plant.

Ambre Gris.—This intestinal concretion is now attributed to different species of Cetaceans, and not to *Physeter macrocephalus* alone.

Ammi officinal.—This is given under a cross reference as *Ajowan*, and the botanical source is now given as *Ammi copticum*, L. (*Ptychotis coptica*, DC., and *P. Ajowan*, DC.).

Aneth.—*Anethum graveolens*, L., is now referred to the genus *Peucedanum*, but without giving the authority for the new name.

Angélique officinale is referred to *Angelica Archangelica*, L.

Angusture vraie is now attributed to *Galipea Cusparia*, A. Sh. (*G. febrifuga*, H. Bn., and *Cusparia febrifuga*, H. B. K., being given as synonyms). Nitric acid is said to produce only a little coloured yellowish (*jaunâtre*) spot, on the internal surface of the bark, but in the samples tried by the writer of these notes it gave a dark reddish-brown colour.

Aristolochie serpentaire.—The term applied to the official part is changed from *rhizome* to *souche*.

Armoise (*Artemisia vulgaris*).—The word "*rhizome*" is substituted for "*racine*," and the same charge is made under "Arnica."

Arrowroot de la Jamaique.—Measurements of the granules are given.

Asa fœtida.—The botanical source of this drug is given as *Ferula Asafœtida*, L., and *Ferula Narthex*, Boiss, and probably also *F. alliacea*, Boiss. The description of the drug is omitted. *Ferula alliacea*, Boiss., yields, according to Dymock (*P. J.*, [3], v., p. 945), the asafœtida known in Bombay as Abusharee Hing, a dark coloured drug which contains about an equal quantity of slices of the root, and which never appears in commerce in Europe. The reason for inserting it here as a source of commercial asafœtida is not obvious.

Asarum (*A. Europœum*, L.), and Asclepiade or Dompte-venin (*Vincetoxicum officinale*), Asperge (*Asparagus officinalis*, L.).—The word "souche" is, in each of these, substituted for racine, while in Aunée, now Grande Aunée, rhizome is the term used to describe what is commonly called the root.

Aya-pana. The synonym *Eupatorium triplinerve* is now used instead of *E. Aya-pana*, Vent. Ventenat is given as the authority for the former name, which by Pritzel ('Nomenclator Botanicus') is attributed to Vahl.

The articles Wormwood, Sea wormwood, Amadou, Alkekengi, Cape aloes, Almonds, Wheat starch, Star anise, Anise, Serpentary, Armoise (*Artemisia vulgaris*), the leaves, rhizome and capitula of Arnica, Arrowroot, Asafœtida, Asparagus rhizome, Elecampane, and Axunge, are the articles marked with an asterisk under "A."

B.

The following are now omitted:—Barbatimao Bark, Mecca balsam, Belladonna seeds, Ben "nuts" (*Moringa disperma*, Guib.), Baume de Liquidambar (*Liquidambar styraciflua*), the grain and gluten of *Triticum sativum* (Blé), Bois d'Aloes, Bois de Brasil Bois nephretique, Bois de rose de Canaries (Lignum rhodium), Buranhem bark (*Chrysophyllum leucophlœum*, Casaretti).

Balsamite odorante: A new synonym, Baumecoq, has been added, and the Latin synonym, *Pyrethrum Tanacetum*, DC., omitted.

Baume du Peru noir.—The synonyms *Myroxylon Pereiræ*, Kl. (*Toluifera Balsamum*, var. *Pereiræ*, H. Bn.) are now adopted, and tests are added. The balsam is stated to be incompletely soluble in diluted alcohol, benzine and ether, giving a clear mixture with acetic acid, acetone, absolute alcohol, and chloroform.

Baume de Tolu.—The botanical name now adopted for the tree is *Myroxylon Toluifera*, H. B. K. (*Toluifera balsamum*, L.). The balsam is described as having an odour recalling that of benzoin and vanilla, and as being completely soluble in cold acetic acid, acetone, alcohol, and chloroform, insoluble in benzine and sulphide of carbon.

Belladonne.—The seed is now official, in addition to the root and leaves. The observation that the root should be recently dried and deprived of the base of the stem is now left out.

Benzoin de Siam.—Is described as containing numerous and large tears and having a very pronounced odour of vanilla. Siam benzoin in lumps has disappeared from commerce of late years, and Siam benzoin consists entirely of loosely agglomerated tears rather than contains them.

Benzoin de Sumatra.—This is described as having an odour of styrax, and the kind known in commerce as Penang benzoin is therefore probably intended to be used. Inferior specimens without tears and full of impurities are to be rejected.

Benoite (*Geum urbanum*).—The "racine" is now become "souche." In the root of this plant the rootlets are all round the root, as in valerian, which is called a "racine."

Bétoine. The synonym *Stachys Betonica*, H. Bn., is now added. The authority for the name is, however, Bentham, not Baillon.

Bistorte.—The word "rhizome" is substituted for "racine."

Bluet ou Barbeau (*Centaurea cyanus*, L.).—The capitulum, instead of the flower only, is now made official.

Boldo.—This by a printer's error is ascribed to *Pneumus boldus*, Mol. (*Boldoa fragrans*, A. Gray).

Brinvillière.—A cross reference under this name, so suggestive of poison, is given to *Spigelia anthelmia*, L.

Buchu or Bucco.—The leaves of *B. crenulata*, Hook., and *B. serratifolia*, W., are now official, in addition to those of *B. betulina*, Bartl.

It may be noticed in passing that Buglosse is not identical with the plant known by that name in England, but includes *Anchusa officinalis*, L., and *A. italica*, L.

Boldo and Belladonna seed are the only two new articles under the heading "B."

The articles marked with an asterisk are Bardane (Burdock root); Balsam of Tolu; African Bdellium; Belladonna root, leaf and seed; Siam Benzoin; Bitter orange, leaf and rind; Bistort root; Spermaceti; Bouillon blanc or Molène (*Verbascum Thapsus*, L.), and Bourrache (*Borago officinalis*).

(*To be continued.*)

SCANDINAVIAN PHARMACY.

ADAPTED BY JOSEPH INCE.

Monsieur Henry Labonne, a Paris pharmacien, has addressed a series of letters to the *Union Pharmaceutique*, and the *Bulletin Commercial*, on the pharmacy of Sweden and Norway, describing his personal experience in those Northern regions. Probably a sketch of some of the more salient incidents of his narrative will interest the English reader.

The route lay through Denmark, Sweden and Norway; across Lapland and as far as North Cape, the furthest extremity of Europe.

The external aspect of a pharmacy is first described, taking as an example the chief laboratories and business premises of Drontheim. This is not the capital but only an important town of Norway.

The house of the Apotekare, like the rest, is made entirely of wood; very large, very clean, and painted white. In front is a large garden; and in this every or almost every indigenous pharmacopœial flower is represented. Add to this, a sundial, a barometer and thermometer visible from a long distance; shells and minerals to form borders; and you see that it is in truth the garden of a *savant*.

It is significant that we reach the Pharmacy by the Apotek gata, that is Pharmacy Street. In all provincial towns in France there is a Church Street, and even a Vicarage Street; but here there is one in honour of Pharmacy. This small fact shows that in these parts the pharmacist is *somebody*, or at least that a Laboratory goes for *something*. The interior presents no peculiarity: a set of bottles on shelves, and scales upon a counter have much the same aspect everywhere.

The master is always well dressed, generally in a frock coat and with a white cravat. He wears this costume not only in town but out in the country; a fact demonstrated in a very small village, to give but one example, between Ostersund and Stockholm.

This village contained altogether from about fifteen to twenty houses, built on a rock; wooden thatched houses only. One amongst them looked like a chateau compared with the rest; on approaching we read with surprise, Apotek.

The pharmacien was in his garden with madame and the household; their dress, almost parisian, and in keeping with the appointments of the house, was in strong contrast with that of the people of the place, who wore the motley costume of Sweden, reminding one of Italy, both by its brilliant colours and the absence of shoes.

Just now thatched roofs were mentioned. These are clods of earth, or more often turf placed on a frame of wood; but their appearance differs altogether from that of French cottages. The roof of the latter is frequently covered with mosses, but moss alone is allowed to grow. In Norway, on the contrary, the wind transports on to these clods of very fertile turf every imaginable grain; and as the inhabitants religiously respect these seeds, the result is that, seen from a distance, these houses of the hamlet seem to have a garden on the top by way of covering; all the more so as this is the country blest by flowers, the native land of the great Linnæus.

There is a reason for the homely construction of these houses; the granite is very hard to work, while fir wood on the contrary costs scarcely anything, and wood houses are warmer than those built of stone. That seems paradoxical, but you have only to enter and see how carefully the smallest cracks are closed by wool, and to reflect that wood is a very bad conductor and consequently that the heat of their comfortable stoves is retained, and you will acknowledge that the construction is quite right.

Unfortunately there is a reverse side to the medal. The first thing you read in any guide respecting any town is that it has been several times destroyed by fire, for which reason there are no ancient monuments in these Northern towns. That also explains why each street and square at Drontheim looks like a field; the fear of fire inspires a dread of overcrowding buildings.

Now let us see something about organization, course of study and practical pharmacy in Scandinavia.

Under the first provisions of legislation no one could establish a pharmacy (apotek) without having obtained the permission of the king. This privilege was only accorded to a new pharmacien in respect of a definite pharmacy in a specified part of the country. But soon the same thing happened as in the case of the tobacconists of France. Those who had obtained the right sold their privileges and many grave inconveniences were the result.

At first the proprietor, taking advantage of competition, only allowed the working of his business to the highest bidder. The latter having bought so dearly soon became hampered by debts and was a struggling man. The matter was complicated by the insecurity arising from the doubtful legal character of his transactions; they were not permitted by the law, but only tolerated by use and custom. To remedy this state of things, legislation distinguished between two sorts of pharmacies (1834).

1. Those just mentioned, designed under the name of privileged royal pharmacies, on condition that the owner should only sell his right by sanction of the king.

2. Personally privileged establishments; the privilege forbidden to be sold. If the pharmacy became vacant, the king, on demand, could award it to another pharmacien in possession of a diploma.

In spite of that, many legal projects had for their object the total abolition of the sale of privileges. Lastly, by an edict of 1873 all traffic of the kind will cease in 1920.

At the present moment (1883) there are only twenty-five pharmacies at disposal; one hundred and sixty-four are *personal*, with forty branch shops called *filial apotek*. The same term occurs in Germany: the French word "succursale" is never used.*

To ensure the cessation of these twenty-five marketable pharmacies a regulation has been adopted.

The interested party up to 1920 receives his privilege at a valuation; the pharmacy thus becomes *personal* on condition always of the repayment to the State every six months of a certain sum calculated with regard to ultimate redemption. In a few years there will be but one class—namely Personal Pharmacies—in Scandinavia. In Sweden where there are four millions and a half inhabitants, their number will amount to about two hundred and thirty. It is true that many of these inhabitants, as the Lapps and the Finns, are not great consumers of pharmaceutical products.

But if pharmaciens are thus protected, they are under certain obligations.

All must be members of the Pharmaceutical Society founded in 1821. Moreover, they are divided into districts, one pharmacien in each district being appointed chief.

The Pharmaceutical Society supports an institute or school where studies for the acquirement of the legal grade are conducted. This pharmaceutical institute is at Stockholm and was founded in 1845.

Independently of the Pharmaceutical Society, it is under the superintendence of the medical department or Collège de Santé of Sweden. The direction of the institute is composed of professors and of two delegates chosen by the Society. Every year a professor must report to the College on the working of the school. If the Society has exhausted its funds, the Diet, or National Assembly, will come to its aid. There are four chief professors, two laboratory assistants, one tutor, making seven in all.

It now remains to describe the regulations under which the diploma of Pharmacien may be gained.

The candidate for a diploma in Swedish-Norway must begin by an apprenticeship of from three to six years in a business house. Then he passes the examination of pharmaceutical student before several pharmaciens and one medical man. Without this examination he is not admitted to the courses at the School of Pharmacy, where alone he can pass his final pharmaceutical examination.

These are not the only formalities to be observed in order to become a student in pharmacy at the school or institute. A year must elapse between his first examination and registration; and he must be provided with certificates from the pharmacien with whom he has served his time. These certificates must declare that he has worked in the laboratory

* Note by Translator. The word "affiliated" is employed by English universities to indicate a dependent college.

for at least one year. Lastly, before admission he must pass in Latin, materia medica, natural history, chemistry and mathematics.

Let us suppose that our young student has successfully complied with the regulations and that he has now entered at the School of Pharmacy; let us see what remains so that he should gain his diploma. His studies are about to finish and but three months remain before he undergoes the last ordeal. On these three months depends his success, for now he must give proof of his practical instruction.

From a literal translation of the Swedish it appears—

1. He must show skill in dispensing a prescription. He must prepare emulsions, ointments, etc., before the teacher of pharmacy.

2. In presence of a professor of chemistry and pharmacy he must make two mineral assays, chemically prove the purity of some substances used in medicine, and detect a poison in a mixture.

3. [An examination which has no analogue in France.] The candidate must answer trade questions put to him by a pharmacien of the town, on suitable methods for preserving remedies, and on a knowledge of prescriptions and pharmaceutical regulations.

4. The professor of natural history and pharmacognosy must ask questions on zoology; particularly on the application of this branch of study to the practice of our art; on posology or the study of doses; and lastly on an acquaintance with the most important antidotes.

5. The candidate must produce his analyses and reports in writing, and reply to two examiners (one chemical, the other pharmaceutical) chosen by all the professors united.

If all goes well the student has only to show his certificates of reception at these multiplied and severe examinations to be rewarded with his diploma; provided always that the fee to the Pharmaceutical Society has been paid.

(*To be continued.*)

HAMAMELIS VIRGINICA.*

The so-called witch hazel derives its name from the similarity of its leaves to those of the English hazel (*Corylus Avellana*, L.). The latter has been used from time immemorial as the attribute or divining rod of witches, and in the earlier days of the American Colonies the American "witch hazel" was made to do duty in place of the English.

The witch hazel (*Hamamelis virginica*, L.), which is also called, in some sections, "winter bloom," "snapping hazel nut," "spotted alder," etc., occurs in nearly all parts of the United States, chiefly in damp woods and thickets, along the moist banks of rivers east of the Mississippi, from the Mexican Gulf to Canada, but according to Pursh, also on hills and in stony places. Usually it is a bush or tall shrub, but sometimes attains a height of 20 feet. Like many other Eastern American trees and bushes, it blossoms late in autumn, from September to November, when the leaves are falling, and contributes its share to the many-coloured hues of the forest in the fall of the year. Bigelow† says of it:—"Among the crimson and yellow hues of the falling leaves there is no more remarkable object than the witch hazel, in the moment of parting with its foliage, putting forth a profusion of gaudy, yellow blossoms, and giving to November the counterfeited appearance of spring."

Its Latin name, *Hamamelis*, is borrowed from the Greek, and was applied by the ancient Greeks to a kind of quince, medlar or pear, but the identity of this cannot now be recognized. It was interpreted by the ancients as meaning "resembling an apple tree," being evidently applied by them to a tree bearing a fruit resembling apples. It is, therefore, rather singular that Linné should have selected this term to denote our witch hazel, which certainly does not fit the above comparison.

G. B. Emerson* says of it:—"The union, on the same individual, of blossoms, faded leaves, and ripe fruits, not very common in any climate, led Linnæus to give to an American plant a Greek name significant of the facts of its producing flowers together with the fruit." Of course, this interpretation is not correct, no such meaning being contained in the term. But the curious appearance of old leaves, flowers, and fruit, on one and the same shrub, is by some supposed to have originated the name "witch hazel."

That the popular notion of the mysterious power of witch hazel, resembling that originally ascribed to the European hazel, was quite prevalent in this country even before the Revolution is testified to by Carver,† who says:—"It is said to be possessed of the power of attracting gold and silver, and that twigs of it are made use of to discover where the veins of these metals lie hid; but I am apprehensive that this is only a fallacious story, and not to be depended on; however, that supposition has given it the name of witch hazel."

A paper in Hutton's 'Mathematics,' and another, by Alfred Burnson, of Prairie du Chien,‡ give some wonderful stories about the power of witch hazel in discovering water. And Porcher§ relates that persons in the upper districts of South Carolina pretend to use the rod with success.

The shrub usually consists of several crooked branching trunks arising from the same root, some 4 to 6 inches in diameter, 5 to 12 (sometimes 20) feet in height, and covered with a smooth, brown bark, the older bark becoming brownish-grey and fissured, and the inner portion being whitish and smooth.

The fruit is a light brown, nut-like, roundish oval capsule or pod, two-celled, which incloses the seeds, but soon bursts elastically into two pieces. It ripens in the summer of the succeeding year.

The two seeds are shining black, with a white hilum, are white, oleaginous and starchy within, and are eatable like hazel nuts. The seed of trees grown abroad germinates but rarely; the plant is there usually propagated by cuttings which strike root very slowly.

There is only one other distinct species of *Hamamelis*, namely, *Hamamelis japonica*, and this differs only by slight characters, namely, by its having more leaf nerves, broader and revolute, brown calyx lobes, and a shorter fruiting calyx.

Medical Uses.

Both the bark and the leaves are used medicinally. The United States Pharmacopœia (1880) recognizes only the leaves, though it would appear that the bark is much more extensively used. Both have a certain degree of fragrance, particularly when fresh, and, when chewed, are at first somewhat bitter, quite astringent, and leave a pungent, sweetish and persistent after-taste. Water as well as alcohol extracts their virtues. They appear to contain, according to Dr. A. Lea, besides the usual plant constituents, a peculiar bitter principle; this autho[r]

* The plant is figured in *Curtis' Botanical Magazine*, No. 463, tab. 6684. Reprinted from the *American Druggist*, January, 1884.

also first drew attention to the large amount of tannin they contain.*

Witch hazel is reputed to be tonic, astringent and sedative. A decoction of the bark (1 oz. to 1 pint) has been found useful in hemorrhages, as well as in diarrhœa, dysentery and excessive mucous discharges. Its supposed beneficial effect in incipient phthisis, where it has been thought to unite anodyne influences with its others, is probably unsupported by facts.

The bark is reported to have long been known to the Indians—which is not at all surprising—as an excellent remedy in swellings and tumours of a painful character, as well as in external inflammations, applied in form of a poultice.

When the negro slaves endeavoured to procure abortion by means of cotton root, miscarriage is said to have been prevented by hamamelis. This is vouched for by Dr. W. W. Durham,† who says:—"At one period of my practice, the negroes used the cotton-root so frequently to produce abortion, that my supply of black haw [*Viburnum prunifolium*, recommended in 1847 by Dr. Phares, of Newtonia, Miss., as an antitocic], became exhausted, and, having heard of the power of the hazel to effect the purpose for which I used the haw, I resorted to it (the hazel) with perfect success. Having only used it for the purpose of preventing abortion from the effects of the cotton-root, I cannot speak of it in other cases."

The decoction may also be used advantageously as a wash or injection for sore mouth, painful tumours, and is probably useful in any cases where a local astringent is indicated, as in leucorrhœa, gleet, conjunctivitis, etc. Professor Stillé states that he has known the decoction or infusion to be used, as a lotion, with apparent benefit, in crusta lactea.

An ointment made with lard and a decoction of white-oak bark, apple-tree bark and witch hazel bark, has been found a valuable application to piles. The same is very generally reported of the so-called white extract of witch hazel, which is said to be made by distilling the fresh bark with a very dilute (6 per cent.) alcohol. This preparation is a popular external remedy in sprains and bruises, and is besides vaunted as a cure for almost every disease flesh is heir to.

Dr. King states that he has used a decoction of equal parts of witch hazel bark, golden seal root (*Hydrastis canadensis*) and lobelia leaves—a strong decoction being made from the first two, then the lobelia leaves added—as a lotion in ophthalmia, with such success, that he succeeded in curing even the most obstinate and long-standing cases; and he adds that other practitioners to whom he communicated this fact have confirmed it.

The decoction was also highly recommended by Dr. James Fountain,‡ of Peekskill, N.Y., and Dr. N. S. Davis,§ in hemorrhage of the lungs and stomach.

Besides the colourless, or distilled "extract," there are several other popular or proprietary preparations, mostly made, probably, by dissolving the soluble parts of the residue left on distilling the bark or leaves.

THE CARDAMOM HILLS OF TRAVANCORE.||

A correspondent of the *Madras Mail* gives the following account of the cultivation of cardamoms in Travancore:—

I spent several days at Odumenshola, and in various visits to the neighbouring Tavalum and gardens, as well as on road-making rounds, I had many opportunities of watching the work of collection and curing the cardamoms. Our ride to a large Tavalum was very interesting as we passed through miles of cardamom forest through which bridle paths had been cut. The Tavalum we visited was some distance beyond the forest, and was a busy scene, as a large amount of cardamoms were being dried on the natural barbacues of rock, and women and children were busy stripping the capsules off the scapes that had just been brought in. From here we rode over a pretty undulating grass country to Callapara where A. had a large permanent camp for warehousing the cardamoms from the neighbouring forests.

From what I could learn there are two varieties of cardamom in the Travancore forests. One crop comes to maturity about October, and the other in January. The varieties appeared to be caused by difference of rainfall and soil; the former growing in a misty wet climate, and poorer soil than the other, which grows in a comparatively dry climate, and fine rich soil. My small experience was confined to the latter variety. Land having been selected, the superintendent has to be applied to for leave to open the garden. Nothing is charged in the way of assessment till the garden comes into bearing, when a rate of 10 per cent. on the crop is charged for land tax. Only certain forests will grow cardamoms, and the presence of a few wild plants is a safe indication of the suitability of the soil. They will not grow in bamboo or reed jungle, nor will they thrive under munga-murrum, mella-murrum, or dammer trees. The best aspect is a northern one and a steep incline is better avoided. The finest gardens, I noticed, were on easy undulating land, and in such situations I was informed they lasted for years. The opening and preliminary work is very simple. Operations begin in April by the cutting down of all undergrowth to 6 or 8 inches in diameter; and here and there large trees of rapid growth are cut down. No burning is done as in coffee clearings, and the felled branches and undergrowth are allowed to rot. In the following October the young cardamoms begin to sprout. Where they are too crowded, it is necessary to thin them out and transplant them into the open spaces, and where the plants have sparely sprouted, it is also usual to sow the ground with seed. The seed should be sown before the monsoon. The growers prefer stocking their gardens with spontaneously grown plants, which they say last longer and come late, bearing earlier than those grown from seed. For two years nothing further is done. In the third the clearing should be weeded, and the small sprinkling of crop gathered. In the fourth year a thorough weeding ought to be done, and the decayed stocks and leaves heaped up between the clump of cardamoms. The garden is now in full bearing, and will require regular attention. The weeding should be done in November, and the crop comes immediately to maturity with the letting in of light and air. Cardamoms require light showery weather in March and April, when the flowering scapes are ready to blossom. In rich soil the scapes will run out to 3 and 4 feet in length, but shorter growths give better results in the way of crop. The failure of showery weather immediately after the blossom will ruin the prospects of the crop, and though the scapes will sometimes throw out a second blossom, the result is generally a poor one. The fluctuations of crop are therefore great, and as hail storms often occur about the blossoming time, the risk and uncertainty of crop is much increased. Cardamoms begin to ripen in November, but it is often late in January before the growers will pick the crop, and a great deal is destroyed by snakes, rats and vermin of every description. Judging from what I saw in the garden, of capsule shells, probably one-third is lost in this way. Chetties from the neighbouring villages in the Madura district are the principal growers, and they usually begin the cardamom harvest when about half the remaining capsules on the scapes are ripe.

The scapes with the cardamoms on are removed to the small collecting stations, and cured by a process of drying in the sun and exposure to the dew. The morning after

§ 'Trans. Amer. Med. Assoc.,' i., 350.

|| Reprinted from the *Tropical Agriculturist*, February 1, 1884.

the collection the capsules are carefully removed from the scapes, and dried on the rocks. The fleshy shell soon loses its green or brown colour under the three or four days' drying, and is then fit to be removed to the weighing stations. Cardamoms lose two-thirds, three-quarters, or even four-fifths of their measure by drying; the exposure to dew is supposed to give a bleached look to the sample. Some cardamoms I noticed had a green tinge which no amount of drying could remove, and was supposed to be caused by the nature of the soil they came from. Could the crop be gathered in, as it ripened, there is no doubt a much better sample could be secured, but I was informed that it would not pay the growers to do this, as the Travancore Government made no distinction in the price for bad or good qualities, and the result was the loss of much of the ripe fruit and the character of the rest being damaged by indiscriminate packing of mature and unripe capsules together. A second curing and winnowing is given at the weighing stations, and there is a further drying and winnowing on the coast when the cardamoms are ready for the buyer. On the coast the best descriptions will realize as much as 4 rupees per lb. (Dutch) but the grower only receives a third of this, and when all deductions from this third are made for watchmen, land tax and other petty charges, the amount really paid is nearer one-fourth than one-third. From notes taken of the cost of cultivation, I was doubtful whether the growers could make anything by the transaction, but the fact of their continuing to cultivate is proof that they do make something. A. considered it paid the growers if they secured two good crops to three bad ones; but he admitted that it was very difficult in bad seasons to get the owners to take in their crops, and he had often to do so at the Government's expense. At one time the produce had been as high as 3000 cwt., but had subsequently dwindled down at a tenth of that quantity. Since A.'s incumbency more land has been opened up and abandoned gardens brought into cultivation, and he had lately a crop of 1500 cwt. A more liberal policy on the part of the Travancore authorities would soon double the cultivation. Nearly all the cardamom growers are British subjects, owing no doubt to the fact that the forests, as far as the Pereyaur, had once been under British jurisdiction. About the second decade of this century, this tract was transferred to the Travancore Government, and the cultivators who were British subjects continued their occupation under the new rule. Roughly estimated, about 20,000 acres were under cultivation, and from what I could learn there was forest land enough available for extending the cultivation five-fold. The yield an acre in even favourable time does not exceed 20 to 25 lb. of cardamoms.

In addition to cardamoms the Travancore Government collect ivory, wax, gallnuts and other hill products, and obtain some revenue from teak and blackwood, and also from cattle grazing fees. Altogether the average nett revenue comes to about 2 lakhs of rupees. No land is granted for otherwise than cardamon cultivation—a wise policy on the part of the Travancore Government, as without losing their forests they obtain a safe though fluctuating revenue. Still there is a good deal of land suitable for grain cultivation which is not allowed to be cultivated though ready with a light tickling of the surface to yield fine crops. The wandering hill tribes in return for Sircar service are alone allowed to grow any grain, and they are restricted to old nursery clearings.

Though the cardamom hills are unoccupied at present by any resident population, there was a time when they must have been inhabited, as ruins of forts, rude carvings, and inscriptions plentifully testify, but there are no traditions of the old inhabitants, and the present hill tribes, according to their own account, are but comparatively recent settlers. The present hill men are of either Tamil or Malayalam origin, and seem to have settled on the hills in the last three hundred years. They are fine men in physique, though living in feverish places, and according to census returns are on the increase. The railway has made the country accessible, as twenty-four hours from the Railway Station of Ammanackenoor would land the sportsmen at some of the finest shikar ground in Southern India.

EMULSION OF COD LIVER OIL.*

BY C. F. SCHLEUSSNER.

The number of formulas already in print is legion, yet the one I have had in use for a long time is one that gives such entire satisfaction to patient, prescriber, and myself, that I think it worthy of more extended knowledge. The formula is not original with myself, but is already in possession of many others of the fraternity, and has in the hands of almost all of them proved a success.

Some, however, have *failed* in the manipulation, and this I think must be due either to unsatisfactory materials or fault in the labour bestowed upon the shaking process. The formula is as follows:—

Powdered gum arabic . . .	180 grains.
Powdered tragacanth . . .	180 grains.
Powdered arrowroot . . .	180 grains.
Cod liver oil	24 fluid ounces.
Syrup	4 fluid ounces.
Water	20 fluid ounces.

The manipulation should follow *exactly* the following directions:—The powders are rubbed in a porcelain mortar of 8 ounces capacity with a small quantity of cod liver oil to a thin smooth paste, more oil being gradually added until 4 or 6 ounces have been added, when it is to be poured into a 5-pint bottle, *which must be clean and perfectly dry*; more oil is then put into the mortar to rinse it, and poured from it into the bottle, adding the balance of the oil. The bottle is then to be vigorously shaken to distribute the powder thoroughly through oil, then add *twelve* fluid ounces of water *all at once*, and shake the bottle *thoroughly, vigorously, and continuously for ten minutes*, when the remaining quantity of water and syrup may be added *all at once*, and the shaking again continued for about two or three minutes.

The yield is three pints of finished emulsion.

Nothing has been said in the above about flavouring, or the addition of other articles so often used in emulsions, such as the hypophosphites, etc.

The emulsion may be made as a stock emulsion by omitting from the above quantities *four ounces* of the water from the last quantity. When desired for any special prescription, it will only be necessary to dissolve the salts ordered or needed in enough water to make six fluid drachms, and pouring some emulsion in a pint bottle, add the solution to it, shake well for a few seconds, then add enough of the stock emulsion to make a pint. Flavouring, dilute sulphuric acid, or any other materials may be added by a similar method in place of a portion of the water omitted.

I have used this method for many months with *entire success* and satisfaction; it keeps well, does not form a crust to the same extent that do many other emulsions, and is more fluid than many that are offered. It has also the advantage of less expense in mucilaginous material.

This formula was temporarily adopted by the New York Committee on unofficial formulas, and was made in their presence to entire satisfaction; yet on being repeated by some members of the committee in their own stores they failed to reproduce as satisfactory an emulsion as that shown the committee and made by them. I can only add that it has never failed in my hands, and that in other instances it has succeeded perfectly on the first trial with others. I only repeat, that if the directions given are *strictly followed* it will never fail. The chief points are best quality of powdered gums and oil, a *clean dry* bottle of *twice* the capacity of total ingredients, vigorous and continuous shaking for ten minutes, the addition of the water *all at once* at the times indicated.

* From the *Pharmaceutical Record*.

The Pharmaceutical Journal.

SATURDAY, MARCH 22, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

MR. WARTON'S BILL TO RESTRICT THE SALE OF PATENT MEDICINES.

PROPHECY, even when only implied, has once more proved to be a risky occupation, for close upon the heels of a very recent somewhat pragmatical assurance that the scheme of Mr. WARTON for dealing with the sale of patent medicines containing poisons "has never had any concrete existence, nor is it likely to have such," the printed Bill has made its appearance. As a copy has been received only just before the time for sending this Journal to press we shall content ourselves now with briefly summarizing what would be the effect of the provisions contained in the seven clauses, the text of which will be found on another page, since in the prospect of a Government measure on the same subject this Bill has not the importance it might otherwise have had.

The legislation proposed would be based upon the presumption that until otherwise proved and authoritatively declared every patent medicine should be deemed a poison within the meaning of the Pharmacy Act, 1868; and, therefore, as the words in the sixteenth section of the Pharmacy Act exempting the making or dealing in patent medicines from the operation of the previous fifteen sections would be repealed, all such articles would come within the general scope of the regulations affecting the sale of scheduled poisons. In order, apparently, to afford an opportunity for the removal of preparations free from poison from this category, it is provided that any person interested in a particular patent medicine, or a vendor or purchaser, may require the same to be analysed by the Pharmaceutical Society of Great Britain, and that if it be found free from any scheduled poison the Society may pass a resolution containing a declaration to that effect, which, upon approval of the Privy Council, would be published in the *London Gazette.* After the expiration of one month from the date of such a notification the proprietor or vendor of this particular preparation would be entitled to affix to the containing vessel or wrapper a label bearing the words, "free from poison." If, on the contrary, the preparation should be found to contain a scheduled poison, a resolution of the Society to that effect, after approval by the Privy Council, would be advertised in the *London Gazette*, and a month hence the preparation would be deemed to be a poison within the meaning of the Pharmacy Act, which indeed, by the provision before mentioned, it would already have been before any analysis. Possibly, however, this provision contemplates the desirability that might sometimes arise for the re-examination of a preparation that has been declared free from poison. It will be observed that no provision is made for the expenses that would be incurred in carrying out this work on behalf of the public.

GLEANINGS IN THE SOUTH-WESTERN PROVINCES OF CHINA.

THE interior of the enormous Chinese empire is still to the Western world so nearly a *terra incognita* as to render all fresh trustworthy information respecting it extremely acceptable. Such a contribution has just appeared in the form of a parliamentary paper containing an account of a four months' journey made in the early part of last year by Mr. HOSIE, a consular agent, through a considerable portion of the important provinces of Se-chuen, Yun-nan and Kuei-chow in the south-west of China. It is principally in these provinces that, in defiance of Imperial edicts, the cultivation of the poppy has been introduced and persevered in, until now it seems to be a tolerated industry, and home-grown opium has become in China a powerful competitor with the Indian drug. Scattered here and there among the observations made on this journey are several that appear to possess sufficient interest for the readers of this Journal to make them worth culling and binding together in a note. The starting-place was Chung-king, the great trade emporium of the province of Se-chuen, and the first objective point was Cheng-tu, its capital, lying about two hundred miles to the north-west. Along the road between these two towns the poppy was a frequent crop, more land being devoted to it in some districts than to anything else; indeed it is there cultivated to such an extent as to affect the price of corn and all other commodities. Nearing the capital the safflower was met with, but here, as in India, its cultivation is decreasing under the joint competition of opium and foreign dyes. Orange groves were also passed, and it was noticed that everywhere the skin of the orange was carefully collected and preserved, the epidermis and the white inner layer, when separated, both finding a place in Chinese medicine. Along this route and everywhere throughout the province there was an abundance of the Chinese "wood oil tree" (*Elæococca vernicia,*) a Euphorbiaceous plant, from the seeds of which an oil is expressed that is used by painters; the tree was also met with in. the provinces of Yun-nan and Kuei chow. Besides coal, a common fuel in this district is charcoal made from ferns, which are placed in a pit and allowed to smoulder, water being constantly sprinkled on the heap to prevent a blaze. A detour was made to visit the famous salt and fire wells at Tzu-liu-ching, where side by side with the sources of the brine are found the means for its evaporation. The fire wells would appear to be associated with petroleum deposits, and give forth an inflammable vapour which is conveyed through bamboo tubes lined with lime to the furnaces where it is burnt under the evaporating pans. The brine varies in quantity and quality; sometimes it is black and sometimes yellow, the latter yielding about half as much salt as the former. The black brine is obtained from a depth of at least two thousand feet and the yellow from seven or eight hundred feet. When the supply is good upwards of three hundred "buckets" of black brine and six or eight hundred of yellow may be obtained in a day. The "buckets" would appear to be large and the brine strong, since it is stated that a bucketful of black brine yields upon evaporation about twenty-four pounds of salt, worth from 6*d.* to 9*d.* The low price of the salt, however, does not save it from adulteration, since we are told that in the manufacture of granular salt bean flour is added to improve its colour.

After reaching the capital of Se-chuen the travellers turned south-west, passing through a fertile plain and reaching Ya-chou, which is considered to be the centre of a medicine-producing country. Here "huang-lien," or gentian, sells for more than its weight in silver, and "hou-po," the bark of the *Magnolia hypoleuca*, is valued at 15 to 30 taels (£4 8*s.* to £8 16*s.*) per catty (1⅓ lb.), the product from the wild tree being most esteemed. It is curious, if not significant, that here and subsequently, next to tea, medicines and coffin boards formed the principal articles of trade. Brick tea is manufactured in Ya-chou, and is said to differ from the article made under the same name at Hankow in consisting of the entire leaf and twig loosely pressed together, whilst the Hankow brick-tea is tea-dust firmly compressed into actual brick shape. Still travelling south and bending towards the west of Yun-nan, the valley of Chien-chang, the great white wax insect egg-producing district, was reached. Wax is not produced here however, since, according to Mr. Hosie, the insects are not reared on the wax-tree, but on a tree called the "tung-chien," and are exported to the districts where the wax-tree is cultivated. If this observation be correct it will help to clear up some obscurity with reference to the origin of the Chinese white wax. The perseverance of the late Daniel Hanbury established it beyond reasonable doubt that one tree, at least, upon which the Chinese wax insect feeds is a species of ash (*Fraxinus chinensis*, Roxb.); but he mentioned in his first communication that the wax had also been attributed to a plant bearing the name "tung-tsing," variously spelt "tong-çin," "toung-thsing," etc., which has been referred to various species of *Ligustrum*. Mr. Hosie speaks very distinctly on the subject. He says:—"It has "been hitherto a matter of surprise that the valley "of Chien-chang should produce the insects and "not the wax, and Chia-ting the wax and not the "insects. The reason is perfectly simple however. "In the prefecture of Chia-ting the wax tree is ex-"tensively grown; in the valley of Chien-chang it "is not. On a small twig of the 'tung-ching' tree, "which a dealer in wax insects has just given me, I "find half a dozen round excrescences about the size "of a pea, and innumerable smaller excrescences, like "minute shellfish, clinging to the bark. On opening "one of the brown glazed pea-shaped excrescences, "thousands of minute whity-brown creatures, whose "movements are all but imperceptible to the naked "eye, are seen. In less than a month hence these ex-"crescences will be collected, transported and sus-"pended on the branches of the wax tree. At first "they spread themselves on the upper side of the "leaves during the night, but hide during the day "from the sun under the leaves. After a time they "spread over the branches and secrete the wax. A "little wax is on the twig of the tung-tching tree "which I hold in my hand."

Among the articles of medicine observed in Se-chuen province, Mr. Hosie mentions "China root," by which, however, he does not mean the rhizome of *Smilax China*, usually designated under that name, but the curious fungoid growth of a species of *Pachyma*,—resembling the "tuckahoo" or "Indian bread" of North America,—which is found on the roots of old fir-trees. Another medicinal substance, "tu-la," was met with after crossing the Yun-nan frontier, which is described as a "brown root-like substance, found underground in the hills." It has a bitter taste, resembling that of quinine, and is said to be efficacious as an antidote to opium and in the treatment of fever. This is not the only case in which a regret arises as to the limits of the traveller's scientific knowledge. In one place he vouches for having inspected a specimen of coarse dusting cloth, "manufactured from the fibrous roots of a coarse grass," the peculiarity of which is that "when it is "dirty it is put in the fire, the dirt is consumed and "the cloth is taken out clean and uninjured and "ready for use." In Yun-nan poppy cultivation and opium collection were noticed almost everywhere, the purple and white-flowered varieties being grown in this province. This province also contributes armadillo skins for use as medicine in the more northerly parts of China. In the southern part of the province of Kuei-chou the proportion of land under poppy cultivation appeared to be still larger than in Se-chuen or Yun-nan, the poppy grown here being a white-flowered variety edged with pink, whilst further north the red and purple-flowered varieties become more common. Before concluding this notice mention may be made of a practice not devoid of a touch of humour. On several occasions Mr. Hosie's attention was attracted to travellers wearing official hats, which he was told indicated that they were candidates making their way northwards to attend the competitive examinations in Pekin. The statement appeared, however, inconsistent with the large quantity of luggage they carried, until the mystery was cleared up by the information that as examination candidates from the provinces travel with a pass exempting their luggage from all taxes *en route* to Pekin, such persons usually carry with them a good supply of opium and Ta-li marble, so that in the event of their being "plucked," they have some consolation in being able to return home with pockets better lined than when they set out, as the result of a little bit of smuggling.

The Medical Acts Amendment Bill passed through Committee in the House of Lords on Thursday.

* * *

On Tuesday, in the House of Commons, in reply to a question, Mr. Hibbert said that it was the intention of the Government to bring forward a measure dealing with the storage of petroleum, after Easter, and that probably it would be thought necessary to introduce the Bill into the House of Lords.

* * *

On Tuesday another decision upon the law relating to the registration of trade marks was contributed by Mr. Justice Chitty. The case was an application to register as a trade mark for extract of meat a device consisting of a portrait of the late Baron Liebig and the words "Brand Baron Liebig," which was opposed by the Liebig's Extract of Meat Company. Mr. Justice Chitty held that it had already been decided that the term "Liebig's Extract of Meat" is common property, and that therefore the applicant was not entitled to register that part of the proposed trade mark which consisted of the words "Brand Baron Liebig." With respect to the portrait, he said it was a common custom to publish portraits of inventors and this portrait was not sufficiently distinctive for registration. Moreover, to suffer the registration to proceed would, in his opinion, be to sanction the registration of a mark calculated to mislead the public into the belief that Liebig's extract of meat was the property of the applicant. On these grounds the application was refused.

The Bill providing for the preparation of a new and legally authoritative United States Pharmacopœia by a committee consisting largely of State hospital officials, which has been introduced into the House of Representatives, is giving rise to a considerable amount of comment, which is not, as a rule, by any means favourable. The *Pharmaceutical Record* says that the whole movement has too much the colour of rivalry between New York and Philadelphia, apparently associating this rivalry especially with the change of publishers. "Some of the gentlemen of the latter city have never been able to disguise their dissatisfaction at the departure of the Pharmacopœia from them, and we do not believe a word of complaint against the scientific part of the present revision of the Pharmacopœia would have been sounded, had the business management been to the liking of the complainants."

It is announced that Sir Lyon Playfair, K.C.B., has consented to allow himself to be nominated at the Montreal meeting of the British Association as President for the meeting to be held in Aberdeen next year.

* * *

In the annual report of the Planters' Association of Ceylon it is stated that owing to the low prices now realized for cinchona bark, together with the liability of the cinchona tree to be short-lived in Ceylon, except in the most favourable localities, a general check has been given to its cultivation in the island. Cinchona is now giving place to tea, and it is thought that the exports, which are estimated to have last year reached six millions of pounds, will soon show a serious decline. The *Times of Ceylon*, too, commenting upon the same subject, says, "the flood is over and now we must expect the inevitable ebb."

* * *

The *Quinologist*, one of the numerous American technical journals, has been discontinued, to allow the editor (Dr. R. V. Mattison) to engage more actively in a business career which "the demands of an active constituency of customers and the exigencies of the situation in regard to the manufacture and sale of the alkaloids of the cinchona bark have rendered of the highest importance."

* * *

The *St. Louis Druggist* reports a case as having recently occurred in Watertown, N.Y., in which a physician, wishing to administer a dose of extract of valerian to a lady patient, went into a pharmacy and helped himself, with the result of administering extract of veratrum instead and nearly killing his patient.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, March 27, at 8 p.m., when a paper will be read by Mr. E. J. Eastes on "Unofficial Indigenous Materia Medica," and a Report upon Organic Chemistry will be made by the Secretary (Mr. Dunstan) on "Some Crystals found in a bottle of Aldehyde."

* * *

At the next meeting of the Chemists' Assistants' Association, to be held on Wednesday, the 26th inst., a paper on "Emulsions," will be read by Mr. Joseph Ince.

* * *

The next meeting of the Manchester Pharmaceutical Association will be held in the Medical Theatre, Owens College, on Tuesday evening, March 25, at 7.30 p.m., when the following papers will be read: "A Note on Kamala," by Mr. W. Kirkby, and "Notes on New Remedies," by Mr. F. C. J. Bird.

* * *

A forthcoming "Physic" course of "Gresham Lectures" is to be devoted to the Food Section of the International Health Exhibition of 1884, and will be given by Dr. E. Symes Thompson. The lectures will be delivered on Tuesday, the 25th inst., and three following days at 6 p.m. It may be convenient to mention that these endowed lectures are delivered in Gresham College, Basinghall Street, and are free to the public.

Provincial Transactions.

YORK CHEMISTS' ASSOCIATION.

On the 11th inst. Mr. H. E. Spencer, L.R.C.P., etc., delivered a very interesting lecture to the members of this Association, in the rooms of the York Young Men's Christian Association, upon the subject of "Disinfectants." Mr. J. Clark presided, and there was a fairly good attendance.

The lecturer remarked that the subject he had chosen was of a very practical character, and of great importance to both medical men and pharmacists. The questions for him to answer were, first, what disinfectants were expected to do; and, secondly, how they were expected to do it. After explaining the difference between a deodorizer and a disinfectant, he said he was inclined to adopt the germ theory of the present day. If it were taken for granted that that theory were true then their business would be to ascertain what would kill the bacteria—or the worst kind of germ—and they then would have obtained a true disinfectant. There was a large number of disinfectants which, for the sake of convenience, he classified as oxidizing agents, which destroyed infective matter by means of oxygen—nature's great purifier. There were also the desulphurating agents, the antiseptics, antizymotics, or to use another word the bactericides, and lastly the absorbents. Referring to the management of a sick room, he said the chief requirements were fresh air, light and cleanliness, and the use of disinfectants did harm if they caused persons to neglect the proper ventilation and cleansing of the sick room. Supposing that a person was suffering from typhoid fever, he showed how necessary it was that everything taken from the room should be thoroughly disinfected. Unless that were done the infection might be conveyed by means of the drain down to the nearest water-course, and thus communicated to persons who lived several miles off and drank the water. According to the germ theory, he said that it was easy enough to undertand how, if an outbreak of typhoid fever took place at Boroughbridge, it could be communicated to the inhabitants of York in the water they drank, even after the water had passed through the water company's filter beds. In cases of scarlet fever, it was believed that the infection was in the dust or scales which came off the patient's skin when he was recovering, and it was, therefore, a very good plan to rub the patient's skin with a disinfectant.

Votes of thanks to the lecturer and the chairman concluded the proceedings.

Proceedings of Scientific Societies.

ROYAL INSTITUTION.

Mesmerism.

At the Friday Evening Meeting held at the Royal Institution on the 14th inst., Mr. J. N. Langley delivered a lecture on "Mesmerism." In opening the subject, the lecturer remarked that for centuries certain passes and movements had been known to exercise a mysterious influence over people. A great advance, however, was made by Mesmer, who wrote a treatise upon "The Theory of the Magnetic Fluid of the Body," whilst in Vienna in 1775, and soon afterwards obtained some notoriety in Paris. Some of Mesmer's researches were placed upon a scientific basis by the late Mr. Braid, of Manchester, who applied the term "Hypnotism" to the results which he obtained, thus making a distinction between the proved and unproved experiments of "Mesmerism." Before proceeding to the main part of his lecture, Mr. Langley gave a brief explanation of the physiological action produced when a stimulus is applied to the skin. He then went on to say that when rays of light from an object fall upon the retina, a nervous action is set up and passed on to the brain, giving an idea of the object from which the rays of light are reflected, and that this nervous action may be carried on to other parts and so cause reflex action, to maintain which does not necessarily require consciousness. The lecturer then drew attention to the fact that if any animal, for example a frog, be turned upon its back, and its early struggles gently and gradually repressed, it will be found after a few minutes to remain in a perfectly quiescent state, though recovering itself at a sudden flash of light, or a sharp noise, as well as upon the application of any cold substance. If allowed to remain in an undisturbed state, however, the frog falls into a deep torpor, in which it remains for a considerable length of time, the senses gradually becoming more incapable of noticing any stimulus as the length of time increases. Whilst in this stupor the limbs of the frog can be placed in any position, and will remain in that position for an indefinite period. If a slight pinch be administered, a corresponding movement of the muscle of the part is observed, and if a more vigorous pinch be given, muscular movement is noticed in all parts of the frog. If, however, two pinches in different parts be administered at the same time, no muscular action is generally apparent. Further, if the body of the frog be stroked, the frog emits one croak for each stroke it receives, but if a pinch be administered at the same time as the stroke, a croak is very seldom obtained. Mr. Langley then followed up his remarks by experimenting upon a frog, an alligator, and a pigeon, all of which he successfully mesmerized, casually mentioning that it is much harder and requires a longer period to obtain birds in the quiescent state. The lecturer then raised a question whether the animal, finding its first struggles for freedom futile, makes a resolve to lie quietly on its back and feign death, and as time goes on becomes more resolved to be unconscious to external influences, or whether the torpor arises from a paralysis of the will. Mr. Langley favoured the latter view, stating that he considered the mesmeric condition to be due to the non-activity of certain nerve centres in the brain. At the close of the lecture an excellent description was given of the method adopted to mesmerize a human being. A bright object is held in the left hand of the operator, about eight to ten inches from the eyes of the subject, who is directed to rivet his attention upon the object, and if at any time his gaze is diverted, the experiment has to be recommenced. At first the pupils of the eye will contract, but afterwards gradually dilate, and when in that state, if the operator carry his right hand from the object towards the eyes, the eyelids will generally close with a vibratory motion. In a few seconds the subject can be compelled to perform any action, if the proper stimulus be applied. After quoting some instances of unconscious mesmerism, Mr. Langley remarked that if a person be told that he will be mesmerized at a certain time, that person, if he thought of the assertion at the appointed time, might mesmerize himself as a consequence.

The following is the text of the important lecture on a Mechanical Theory of Magnetism delivered by Professor Hughes, on the 29th ult.:—

Theory of Magnetism.

BY PROFESSOR D. E. HUGHES, F.R.S., M.R.I.

The theory of magnetism, which I propose demonstrating this evening, may be termed the mechanical theory of magnetism, and, like the now well-established mechanical theory of heat, replaces the assumed magnetic fluids and elementary electric currents by a simple, symmetrical, mechanical motion of the molecules of matter and ether.

That magnetism is of a molecular nature has long been accepted, for it is evident that, no matter how much we divide a magnet, we still have its two poles in each separate portion, consequently we can easily imagine this division carried so far that we should at last arrive at the molecule itself possessing its two distinctive poles, consequently all theories of magnetism attempt some explanation of the cause of this molecular polarity, and the reason for apparent neutrality in a mass of iron.

Coulomb and Poisson assume that each molecule is a sphere containing two distinct magnetic fluids, which in the state of neutrality are mixed together, but when polarized are separated from each other at opposite sides; and, in order to explain why these fluids are kept apart as in a permanent magnet, they had to assume, again, that each molecule contained a peculiar coercive force, whose functions were to prevent any change or mixing of these fluids when separated.

There is not one experimental evidence to prove the truth of this assumption; and as regards coercive force, we have direct experimental proof opposing this view, as we know that molecular rigidity or hardness, as in tempered steel, and molecular freedom or softness, as in soft iron, fulfil all the conditions of this assumed coercive force.

Ampère's theory, based upon the analogy of electric currents, supposes elementary currents flowing around each molecule, and that in the neutral state these molecules are arranged hap-hazard in all directions, but that magnetization consists in arranging them symmetrically.

The objections to Ampère's theory are numerous. 1st. We have no knowledge or experimental proof of any elementary electric currents continually flowing without any expenditure of energy. 2nd. If we admit the assumption of electric currents around each molecule, the molecule itself would then be electro-magnetic, and the question still remains, What is polarity? Have the supposed electric currents separated the two assumed magnetic fluids contained in the molecule, as in Poisson's theory? or are the electric currents themselves magnetic, independent of the iron molecule?

In order to produce the supposed heterogeneous arrangement of neutrality, Ampère's currents would have either to change their position upon the molecule, and have no fixed axis of rotation, or else the molecule, with its currents and polarities, would rotate, and thus be acting in accordance with the theory of De la Rive. 3rd. This theory does not explain why (as in the case of soft iron) polarity should disappear whenever the exciting cause is removed, as in the case of transient magnetization. It would thus require a coercive force in iron to cause exactly one-half of the molecules to instantly reverse their direction, in order to pass from apparent external polarity to that of neutrality.

The influence of mechanical vibrations and stress upon iron in facilitating or discharging its magnetism, as proved by Matteucci, 1847, in addition to the discovery by Page, 1837, of a molecular movement taking place in iron during its magnetization, producing audible sounds, and the discovery by Dr. Joule, 1842, of the elongation of iron when magnetized, followed by the discoveries of Guillemin, that an iron bar bent by a weight at its extremity would become straight when magnetized; also that magnetism would tend to take off twists or mechanical strains of all kinds—together with the researches of Matteucci, Marianini, De la Rive, Sir W. Grove, Faraday, Weber, Wiedemann, Du Moncel, and a host of experimenters, including numerous published researches by myself—all tend to show that a mechanical action takes place whenever a bar of iron is magnetized, and that the combined researches demonstrate that the movement is that of molecular rotation.

De la Rive was the first to perceive this, and his theory, like those of Weber, Wiedemann, Maxwell and others, is based upon molecular rotation. Their theories, however, were made upon insufficient data, and have proved to be wrong as to the assumed state of neutrality, and right only where the experimental data clearly demonstrated rotation.

I believe that a true theory of magnetism should admit of complete demonstration, that it should present no anomalies, and that all the known effects should at once be explained by it.

From numerous researches I have gradually formed a theory of magnetism entirely based upon experimental results, and these have led me to the following conclusions:—

1. That each molecule of a piece of iron, as well as the atoms of all matter, solid, liquid, gaseous, and the ether itself, is a separate and independent magnet, having its two poles and distribution of magnetic polarity exactly the same as its total evident magnetism when noticed upon a steel bar-magnet.

2. That each molecule, or its polarity, can be rotated in either direction upon its axis by torsion, stress, or by physical forces such as magnetism and electricity.

3. That the inherent polarity or magnetism of each molecule is a constant quantity like gravity; that it can neither be augmented nor destroyed.

4. That when we have external neutrality, or no apparent magnetism, the molecules or their polarities arrange themselves so as to satisfy their mutual attraction by the shortest path, and thus form a complete closed circuit of attraction.

5. That when magnetism becomes evident, the molecules or their polarities have all rotated symmetrically, producing a north pole if rotated in a given direction, or a south pole if rotated in the opposite direction. Also, that in evident magnetism we have still a symmetrical arrangement, but one whose circles of attraction are not completed except through an external armature joining both poles.

6. That we have permanent magnetism when the molecular rigidity, as in tempered steel, retains them in a given direction, and transient magnetism whenever the molecules rotate in comparative freedom, as in soft iron.

Experimental Evidences.

In the above theory the coercive force of Poisson is replaced by molecular rigidity and freedom; and as the effect of mechanical vibrations, torsion, and stress upon the apparent destruction and facilitation of magnetism is well known, I will, before demonstrating the more serious parts of the theory, make a few experiments to prove that molecular regidity fulfils all the requirements of an assumed coercive force.

I will now show you that if I magnetize a soft iron rod, the slightest mechanical vibration reduces it to zero; whilst in tempered steel or hard iron, the molecules are comparatively rigid, and are but slightly affected. The numerous experimental evidences which I shall show prove that whilst the molecules are not completely rigid in steel, they are comparatively rigid when compared with the extraordinary molecular freedom shown in soft iron. (*Experiments shown.*)

If I now take a bottle of iron filings, I am enabled to show how completely rigid they appear if not shaken; but the slightest motion allows these filings to rotate and short circuit themselves, thus producing apparent neutrality. Now I will restore the lost magnetism by letting the filings slowly fall on each other under the influence of the earth's magnetic force; and here we have an evident proof of rotation producing the result, as we can ourselves perceive the arrangement of the filings. (*Experiment shown.*)

If I take this extremely soft bar of iron, you notice that the slightest mechanical tremor allows molecular rotation, and consequent loss or change of polarity; but if I put a slight strain on this bar, so as to fasten each molecule, they cannot turn with the same freedom as before, and they now retain their symmetrical polarity like tempered steel, even when violently hammered. (*Experiment shown.*)

We can only arrive at one conclusion from the experiment, viz., that the retention of apparent magnetism is simply due to a frictional resistance to rotation; and whenever this frictional resistance is reduced, as when we take off a mechanical strain, or by making the bar red hot, the molecules then rotate with an almost inconceivable freedom from frictional resistance.

Conduction.

You notice that if I place this small magnet at several inches' distance from the needle, it turns in accordance with the pole presented. How is the influence transmitted from the magnet to the needle? It is through the atmosphere and the ether, which is the intervening medium. I have made a long series of researches on the subject, involving new experimental methods, the results of which are not yet published. One result, however, I may mention. We know that iron cannot be magnetized beyond a certain maximum, which we call its saturation point. It has a well-defined curve of rise to saturation, agreeing completely with a curve of force produced by the rotation of a bar magnet, the force of which was observed from a fixed point. I have completely demonstrated by means of my magnetic balance (*shown in the Library*) that our atmosphere, as well as Crookes' vacuum, has its saturating point exactly similar in every respect to that of iron: it has the same form through every degree. We cannot reduce nor augment the saturating point of ether; it is invariable, and equals the finest iron. We may, however, easily reduce that of iron by introducing frictional resistance to the free motion of its molecules.

From consideration of the ether having its saturating point, I am forced to the conclusion that it could only be explained by a similar rotation of its atoms as demonstrable in iron.

Reflection would teach us that there cannot be two laws of magnetism, such as one of vibrations in the ether and rotations in iron. We cannot have two correct theories of heat, light, or magnetism; the mode of motion in the case of magnetism being rotation, and not vibration.

Let us observe this saturation point of ether compared with iron. I pass a strong current of electricity in this coil. The coil is quite hot, so we are very near its saturation. I now place this coil at a certain distance from the needle (8 inches); we have now a deflection of 45° on the needle. I now introduce this iron core, exactly fitting the interior previously filled by the ether and atmosphere. Its force is much greater, so I gradually remove this coil to a distance, where I find the same deflection as before (45°). This happens to be at twice the distance, or 16 inches, so we know, according to the law of inverse squares, that the iron has four times the magnetic power of the ether. But this is only true for this piece of iron: with extremely fine specimens of iron I have been enabled to increase the force of the coil forty times, whilst with manganese steel containing 10 per cent. of manganese it was only 30 per cent. superior. We see here that the atmosphere is extremely magnetic. Let us replace the solid bar by iron filings. We now only have twice the force of ether. Replace this by a bottle of sulphate of iron in a liquid state: it is now a mere fraction superior to the atmosphere; and if we were still further to separate the iron molecules, as in a gaseous state, it is reasonable to suppose that if we could isolate the iron gas from that of ether, that iron gas would be strongly diamagnetic, or have far less magnetic capacity than ether, owing to the great separation of its molecules. These are assumptions, but they are based upon experimental evidences, which give it value.

Let us quit the domain of assumption to enter that of demonstration. Here I have a long bar of neutral iron. If I place this small magnet at one end, we notice that its pole has moved forward three inches, having a consequent point at that place. Let us now vibrate this rod and you notice the slow but gradual creeping of the conduction until at the end of two seconds it has reached 14 inches. The molecules have been freed from frictional resistance by the mechanical vibrations, and have at once rotated all along the bar. (*Experiment shown.*) Let us repeat this experiment by heating the rod to red heat. You notice the gradual creeping or increased conduction as the heat allows greater molecular freedom. (*Experiment shown.*) Let us now again repeat this experiment by sending a current of electricity through the bar. You notice the instant that I touch the bar with this wire, conveying the current through it, that we have identically the same creeping forwards, no matter what direction of the current. (*Experiment shown.*) If you simply looked at the effects produced, you could not tell which method I had employed; either mechanical vibrations, heat vibrations, or electrical currents. Consequently, knowing the two first to be modes of motion, it is fair to assume that an electrical current is a mode of motion, the manner of which is at present unknown; but that there is a molecular disturbance in each case is evident from the experiments shown.

Neutrality.

If I take this bar of soft iron, introduce it in the coil, and pass a strong electric current through the coil, you notice that it is intensely magnetic, holding up this large armature of iron and strongly deflecting the observing needle. I now interrupt the current, the armature falls, and the needle only shows traces of the previous intense magnetization. What has become of this polarity? or what has caused this sudden neutrality? Coulomb supposes that the magnetic fluids have become mixed in each molecule, thus neutralizing each other. Ampère supposes that the elementary currents surrounding each molecule have become heterogeneous. De la Rive, Wiedemann, Weber, Maxwell, and all up to the present time have accounted for this disappearance as a case of mixture of polarities or heterogeneous arrangement.

My researches proved to me that neutrality was a symmetrical arrangement; I stated this in my paper upon the theory of magnetism to the Royal Society last year. I have since made a long series of researches upon this question, and my paper upon this subject will shortly be read at the Royal Society. This paper will demonstrate beyond question—1. That a bar of iron under the influence of a current or other magnetizing force is more strongly polarized on the outside than in the interior; that its degree of penetration follows the well-defined law of inverse squares, up to the saturation point of each successive layer. 2. The instant that the current ceases, a reaction takes place, the stronger outside reacting upon the weaker inside, completely reversing it, until its reversed polarity exactly balances the external layers.

We might here suppose that there existed two distinct polarities at the same end of a neutral bar, but this is only partially true, as the rotation of the molecules from the inside to the exterior is a gradual, well-defined curve, perfectly marked, as shown in the diagrams. (*Diagrams explained.*) We see from these that in a large solid bar the reversed polarity would be in the interior, but in a thin bar under an intense field the reversed polarity would be on the outside. Thus a bar which had previously strong north polarity under an external influence would, the instant it formed its neutrality, have a north polarity in the interior covered or rendered neutral by an equal south exterior, the sum of both giving the apparent neutrality that we notice. I must refer all interested upon this question to my paper shortly to be read, but I will make a few experiments to demonstrate this important fact.

If I take this piece of soft steel and magnetize it strongly, it has a strong remaining magnetism, or only partial neutrality. If I now heat this steel to redness, or put it into a state of mechanical vibration, the remaining magnetism almost entirely disappears, and we have apparent neutrality. This piece of steel being thin ($\frac{1}{2}$ millimetre), I know that the outside is reversed to its previous state. I place this piece of steel in a glass vase near the observing needle, and at present there seems no polarity. I now pour dilute nitric acid upon it, filling up the vase. The exterior is now being dissolved, and in a few minutes you will see a strong polarity in the steel, as the exterior reversed polarity is dissolved in the acid. (*Experiment shown.*)

Let us observe this by a different method. I take two strips of hard iron, and magnetize them both in the same direction.

If I place them together and then separate them, there seems no change, although in reality the mere contact produced a commencement of reversal. Let us vibrate them whilst together, allowing the molecules greater freedom to act as they feel inclined; and now on separating we see that one strip has exactly the opposite polarity to the other, both extremely strong, but the sum of which when placed together, is zero or neutrality. (*Experiment shown.*)

Let us take two extremely soft strips placed together, and magnetized whilst together. On withdrawal of the inducing force, the rods are quite neutral. (*Experiment shown*).

We now separate these strips, and find that one is violently polarized in one direction, whilst the other is equally strong in the reversed; the sum of both being again zero.

We might suppose that the reaction is due to having separate bars. I will now demonstrate that this is not the case by magnetizing this large ⅜-inch bar with a magnetizing force just sufficient to render the rod completely neutral when held vertically or under the earth's magnetic influence. (*Experiment shown.*)

You notice that it is absolutely neutral, all parts as well as the ends showing not the slightest trace of polarization. I reverse this bar, and you perceive that it is now intensely polarized. This is due to the fact that the earth's influence uncovers or reverses the outside molecules, and consequently they are now of the same polarity as its interior. Upon reversing this rod, the magnetism again disappears, and reappears if turned as previously. We have thus a rod which appears intensely magnetic when one of its ends is lowermost, whilst if that same end is turned upwards all traces of magnetism disappear.

These and several other demonstrations which I shall now show you (proving the enormous influence which thickness of a bar has in the production of neutrality or its retention of magnetism) are simple lecture demonstrations. For the complete proof of my discovery of neutral curves I must refer you to my forthcoming paper upon this subject. (*Experiments shown proving the great influence of a thickness of a bar upon its retentive and neutral powers.*)

Inertia.

I have remarked in my researches that the molecules have true inertia, that they resist being put in motion, and if put in motion will vanquish an opposing resistance by their simple momentum. To illustrate this, I take this large ⅜-inch bar, magnetize it so that its south pole is at the lowest end. We know that the earth's influence is to make the lower end north. I now gently strike it with a wooden mallet, and the rod immediately falls to zero. I continue these blows, but the rod obstinately refuses to pass the neutral line to become north, the reason being in so doing it would have to change the whole internal reversed curve that I have discovered. It requires now extremely violent and repeated blows from the mallet to make it obey the earth's influence.

Let us repeat this experiment by starting the molecule rapidly in the first instance. The rod is now magnetized south as before. I give one single sharp tap; the molecules run rapidly round, pass through neutrality, breaking up its curve, and arrive at once to strong north polarity. (*Experiment shown.*)

A very extraordinary effect is shown if we produce this effect by electricity; it then almost appears as if electricity itself had inertia. I take this bar of hard iron and magnetize it to a fixed degree. On the passage of the current, you notice that the magnetism seems to be increased as the needle increases its arc, but this is caused by the deflection of the electric current in the bar. The current is now obliged to travel in spirals, as my researches have proved to me that electricity can only travel at right angles to the magnetic polar direction of a molecule, consequently in all permanent magnets the current must pass at right angles to the molecule and its path will be that of a spiral. Let us replace this bar by one from a similar kind of iron well annealed. The molecules here are in a great state of freedom. We now magnetize this rod to the same degree as in the previous case; the electric current now, instead of being deflected, completely rotates the molecules, and the needle returns to zero, all traces of external magnetism having ceased. The electricity on entering this bar should have been forced to follow a tortuous circular route, its momentum was, however, too great for the molecules, and they elected to turn, allowing the electricity to pass in a straight line through the bar. Thus, in the first instant, magnetism was the master directing the course of the current; in the last, it became its servant, obeying by turning itself to allow a straight path to its electric master. (*Experiment shown.*)

Superposed Magnetism.

It is well known that we can superpose a weak contrary polarity upon an internal one of an opposite name. I have been enabled thus to superpose twenty successive stratas of opposite polarities upon a single rod, by simply diminishing the force at each reversal. I was anxious to prepare a steel wire so that in its ordinary state it would be neutral, but that in giving it a torsion to the right one polarity would appear, whilst a torsion to the left would produce the opposite polarity. This I have accomplished by taking ordinary soft steel drill wire and magnetizing it strongly whilst under a torsion to the right, and more feebly with an opposite polarity when magnetized under torsion to the left.

The power of these wires, if properly prepared, is most remarkable, being able to reverse their polarity under torsion, as if they were completely saturated; and they preserve this power indefinitely if not touched by a magnet. It would be extremely difficult to explain the action of the rotative effects obtained in these wires under any other theory than that which I have advanced; and the absolute external neutrality that we obtain in them when the polarities are changing we know, from their structure, to be perfectly symmetrical.

I was anxious to show some mechanical movement produced by molecular rotation, consequently I have arranged two bells that are struck alternately by a polarized armature put in motion by the double polarized rod I have already described, but whose position, at 3 centimetres distant from the axis of the armature, remains invariably the same. The magnetic armature consists of a horizontal light steel bar suspended by its central axle; the bells are thin wineglasses, giving a clear musical tone loud enough, by the force with which they are struck, to be clearly heard at some distance. The armature does not strike these alternately by a pendulous movement, as we may easily strike only one continuously, the friction and inertia of the armature causing its movements to be perfectly dead-beat when not driven by some external force, and it is kept in its zero position by a strong directive magnet placed beneath its axle.

The mechanical power obtained is extremely evident, and is sufficient to put the sluggish armature in rapid motion, striking the bells six times per second, and with a power sufficient to produce tones loud enough to be clearly heard in all parts of the hall of the Institution.

There is nothing remarkable in the bells themselves, as they evidently could be rung if the armature was surrounded by a coil, and worked by an electric current from a few cells. The marvel, however, is in the small steel superposed magnetic wire producing by slight elastic torsions from a single wire, 1 millimetre in diameter, sufficient force from mere molecular rotation to entirely replace the coil and electric current. (*Experiment shown by ringing the bells by the torsion of a small $\frac{1}{16}$ inch wire placed 4 inches distant from bell-hammer.*)

Correlation of Forces.

There is at present a tendency to trace all physical forces to one, or rather a variation of modes of motion. In my last experiment the energy of my arm was transformed in the wire to molecular motion, producing evident polarity; this, again, acted upon the ether, putting the needle-hammer into mechanical motion. This by its impact upon the glass bells transformed its motions into sonorous vibration; but this does not mean that we can convert directly sonorous vibrations into magnetism, or *vice versâ*.

Let us take this soft iron rod; it seems quite neutral, although we know that the earth's magnetism is trying to rotate its molecules to north polarity at its lowest extremity. We now put it in mechanical vibration by striking it gently with a wooden mallet; the molecules at once rotate, and we have the expected strong north polarity. Let us repeat this experiment by employing heat, and here, again, at red heat an equally strong north polarity appears.

Again we repeat, and simply pass an electric current of no matter what direction; again the same north pole appears. Thus these forces must be very similar in nature, and may be fairly presumed to be vibrations, or modes of motion, having no directive tendency except a slight one, as in the case of electricity. For the same three forces render the rod perfectly neutral, even when previously magnetized, when placed in a longitudinally neutral field, as east and west.

Motion of the molecules gives rise to external magnetism to a rod previously neutral, or renders it neutral when previously magnetized; in other words, it simply allows the molecules to obey an external directing influence; the only motion, therefore, is during a change of state or polarity. If there is constant polarity, there is no consequent motion of the molecules: in fact, the less motion of any kind that it can receive, the more perfect its retention of its previous position; consequently, constant magnetism cannot be looked upon as a mode of motion, neither vibratory nor rotatory; it is an inherent quality of each molecule, similar in its action to its chemical affinity, cohesion, or its polar power of crystallization. A molecule of all kinds of matter has numerous endowed qualities; they are inherent, and special in degree to the molecule itself. I regard the magnetic endowed qualities of all matter or ether to be inherent, and that they are rendered evident by rotation to a symmetrical arrangement in which their complete polar attractions are not satisfied.

Time will not allow me to show how completely this view explains all the phenomena of electro-magnetism, diamagnetism, earth currents—in fact, all the known effects of magnetism—up to the original cause of the direction of the molecules of the earth. To explain the first cause of the direction of the molecules of the earth would rest altogether upon assumption as the first cause of the earth's rotation, and of all things down to the inherent qualities of the molecule itself.

The mechanical theory of magnetism which I have advocated seems to me as fairly demonstrable as the mechanical theory of heat, and it gives me great pleasure to have been allowed to present you with my views on the theory of magnetism.

SOCIETY OF ARTS.

Alloys used for Coinage.

The first of what promises to be an interesting course of four Cantor lectures by Professor W. Chandler Roberts, Chemist of the Royal Mint, upon the "Alloys used for Coinage," was delivered on Monday, the 17th inst., at the Society of Arts. This lecture was principally confined to noticing the gradual development of the process of coining, the subject of the composition of the coins in ancient and modern times also being slightly touched upon. Although barter generally answered for the purpose of obtaining the necessaries of life, it is evident that when a higher stage of civilization was attained it was necessary that some recognized medium of exchange should be determined upon. The Chinese manufactured coins of the shape of the equivalent article of commerce, the lecturer showing an engraving of a coin representing a shirt. At first the currency was not confined to any particular object, stone and bronze implements being used amongst other things, and none of them possessing any stamp authoritatively indicating their real value. Circular masses of metal were then used, until the Greeks, who were the first to strike their coins, in the 7th century, B.C., introduced a semi-spherical form, on one side of which a head or some figure was impressed by means of a soft iron or bronze die, whilst the reverse only bore signs of the nail-head, used to keep the metal in position whilst it was being struck. The engraving rapidly improved, and the lecturer considered that some of the coins he exhibited might be classed amongst high works of art. The Romans cast a great number of their coins, using moulds of sand for the operation; an ingenious method was also used for casting by the Chinese and Japanese, the metal being run into long narrow bags of wired wet canvass, ingots being formed from which they manufactured their blanks. In 1515 Leonardo da Vinci introduced an improved form of cutter and die, which ensured coins equal in point of size; the coins, as stamped from the sheets of metal, passed up inside the cutter, whilst in the die process, the coin was encircled by a metal ring to prevent the flattening consequent from the blows of the hammer. A similar form was used until a few years ago in the Scotch mint, the cutter being solid and fitting loosely into a hollow anvil; this was also the origin of the monkey die. In 1540 Benvenuto Cellini invented the screw-press, which gradually superseded the use of the hammer. Professor Roberts considered that it would be wasting time to give a full description of the methods of coinage used in the Royal Mint at the present time, as a very complete one is given in the new edition of the 'Encyclopædia Britannica,' and notices of all new machines are given in his official annular reports; he therefore only glanced at the chief points for ensuring the accuracy of the composition of the coins. The ingots are first carefully assayed and brought up to the required standard and then made into the form of bars. These bars are rolled out between chilled iron rollers into thin layers, out of which disks are cut, and these disks are again assayed. It is found necessary to "pickle" the blanks in sulphuric acid to remove the superficial layer of base metal. It is generally known that pure gold and silver is not used for coinage, but it is not so widely known that the amount of base metal in the alloys is guarded by most rigorous laws; it will be seen how necessary this is, when it is known that there are between seven and eight hundred tons of alloy of gold and copper in circulation at the present time. It is also important that money should be made of some metal not too common. At the close of the lecture, Professor Roberts remarked upon the relation of the mechanism employed in coinage in regard to scientific progress; at times the mechanism was far behind and at other times far in advance of the progress of science. Steel dies were not used until A.D. 300, whilst nearly all the work was done by hand till 1662. Rollers were known long before their introduction into mints, but now sheets could be rolled with such accuracy as to be reckoned to the $\frac{1}{2000}$th part of an inch. Milling until 1882 had been performed by means of a split collar, but improvements had now been made in that operation.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, March 13, Mr. H. G. Greenish, Vice-President, in the chair. Mr. T. S. Dymond read some—

Notes on the Synthesis of Uric Acid.

BY T. S. DYMOND.

The synthesis of uric acid having been effected by Herr Horbaczewski, and his report on the work published in the *Berichte der deutschen chemischen Gesellschaft*, November, 1882, I attempted to confirm his experiments and brought the results of part of my work before this Association last year. Having now completed my work on the subject, I venture to bring the matter before you again.

The production of uric acid by synthesis is very important, because its composition has long been a point of dispute, and this discovery will aid in finding its true chemical constitution, and when this is once determined, we shall be better able to understand its occurrence in the animal economy, and to regulate its formation in the animal tissues in complaints brought on by the deposition of its compounds.

The synthesis of urea, another important constituent of urine, was accomplished more than seventy years ago from ammonium cyanate, but uric acid has never before been obtained by synthesis. Uric acid occurs in the excrements or tissues of carnivorous animals only, though at the same time it has been found that, in the case of human beings, a vegetarian diet makes but little difference in the quantity of uric acid produced, and has even been noticed to increase it.

It occurs very largely in serpents' dung and guano as the ammonium salt, and in small quantities in human urine chiefly as the sodium salt. Occasionally a deposition of the more insoluble urates or uric acid takes place within the bladder, producing a variety of urinary calculus, or as the sodium salt within the muscles, producing gout. It is the product of the proteid tissues, and is derived from the nitrogenous elements of the food. Chiefly produced in the liver it is taken up by the blood, passed through the body, filtered out by the kidneys, and carried away by the urine.

The following is the method by which Herr Horbaczewski effected the synthesis of uric acid:—

One part of pure glycocine was mixed with 10 parts of urea, and the mixture was heated in a metal bath at 200°—230° C., till the fused mass, at first clear and colourless, had become golden brown and thick. When cold this was dissolved in dilute potash, and the solution supersaturated with ammonium chloride. Ammoniacal solutions of silver and magnesia were then added and the liquid was filtered. The precipitate was well washed with solution of ammonia, and decomposed with solution of sulphide of potassium, and again filtered. The filtrate was saturated with hydrochloric acid and the whole concentrated, when the impure uric acid separated out, and was purified by twice repeating the process, and finally, by washing with alcohol, ether and carbon bisulphide. The substance thus obtained was identified as uric acid by its crystalline form, by the action on copper and silver solutions, by the murexide test, and by its insolubility in water, alcohol, and ether.

In order to confirm this experiment I tried it myself, but at first failed, apparently because equal parts of urea and glycocine were used. Having since used 10 parts of urea to 1 of glycocine I have been more successful. The following are a few notes on my work:—

Glycocine may be obtained by three methods:—

I. By the action of either sulphuric acid or potash on gelatine. By this method amido-caproic acid (leucine) and amido-acetic acid (glycocine) are formed thus—

$$C_6H_{10}N_2O_2 = \left\{\begin{matrix} C_5H_{10}.NH_2 \\ CO.OH \end{matrix}\right. + \left\{\begin{matrix} CH_2.NH_2 \\ CO.OH \end{matrix}\right. + xNH_3, \text{ etc.}$$

The glycocine being insoluble in alcohol is thus separated from the leucine, which is soluble. Having some of that prepared by this method, I purified it from the leucine with which it was still contaminated, by washing with absolute alcohol, and then, by a long series of recrystallizations from water purified it from the colouring matter and obtained this pure specimen.

II. By the action of ammonia on bromacetic acid, a method only interesting scientifically, as it shows what might be the constitution of glycocine:—

$$\left\{\begin{matrix} CH_2.Br \\ CO.OH \end{matrix}\right. + 2NH_3 = NH_4Br + \left\{\begin{matrix} CH_2.NH_2 \\ CO.OH \end{matrix}\right.$$

III. By the action of hydrochloric acid on hippuric acid, an important constituent of cattle urine. I have also prepared glycocine by this method. The hippuric acid was boiled with strong hydrochloric acid, dark oily drops of benzoic acid being formed as the hippuric acid disappeared. After diluting and cooling, the benzoic acid was filtered off, and the solution containing hydrochlorate of glycocine was evaporated until most of the free acid was expelled, and then neutralized by ammonia and precipitated by absolute alcohol. The glycocine was freed from the ammonium chloride by washing with more absolute alcohol, and finally crystallized from water. The reaction is as follows:—

$$\left\{\begin{matrix} CH_2.NH(C_6H_5.CO) \\ CO.OH \end{matrix}\right. + \left\{\begin{matrix} H \\ HO \end{matrix}\right. = \left\{\begin{matrix} CH_2.NH_2 \\ CO.OH \end{matrix}\right. + \left\{\begin{matrix} C_6H_5 \\ CO.OH \end{matrix}\right.$$

Glycocine in many respects resembles sugar; its taste is very sweet, and it is also difficult to decolorize by crystallization alone; it is hence called sugar of gelatine, but it more readily crystallizes than sugar, being not so soluble in water. It is distinguished from cane sugar but resembles grape sugar by the reduction of copper solutions and in other ways. I found that it is distinguished from grape sugar by not giving the borax reaction, as it has been shown by Mr. Dunstan many of the polyhydric alcohols do. This indeed is what one would expect, as glycocine has not the constitution of an alcohol. Glycocine may be represented as acetic acid where one atom of hydrogen of the methyl group has been replaced by amidogen; or it may be perhaps acetic acid where one atom of the acid group oxatyl has been replaced by amidogen— $\left\{\begin{matrix} CH_3 \\ CO\ .\ ONH_2, \end{matrix}\right.$ for it appears to be not a true acid, as it has a sweet taste, no reaction on litmus paper, and crystallizes from alcohol, in the presence of ammonia.

Urea occurs in most urine, in human blood and in many animal secretions, and is prepared either by the exhaustion of evaporated urine with alcohol, or better by the action of sulphate of ammonium on a solution of cyanate of potassium. Cyanate of ammonium is found in solution, which on boiling with water yields the isomeric body urea. Urea may also be produced by the action of heat on carbonate of ammonium, one of the constituents of commercial ammonium carbonate. Cyanate of ammonium is first formed and this is changed into urea.

$$NH_4NH_2CO_2 = H_2O + NH_4CNO = (NH_2)_2CO$$

$$\text{or}\quad \begin{array}{c} H-N-H \\ | \\ CO\ .\ ONH_4 \end{array} \qquad \begin{array}{c} N \\ ||| \\ C-O-NH_4 \end{array} \qquad \begin{array}{l} O \\ ||\ /NH_2 \\ C—NH_2. \end{array}$$

Urea is, then, diamide of carbonyl or carbamide.

With these two substances, urea and glycocine, I have made the following experiment:—1 drachm of glycocine was mixed with 10 of urea and heated in a beaker by an oil bath to a temperature of 230° C. The mass soon liquefied and a copious evolution of ammonia together with a gradual darkening in colour followed. When the evolution of gas lessened the beaker was removed and allowed to cool. The hard residue was dissolved in potash and the solution decolorized with animal charcoal (a great improvement on the process of purification proposed by Horbaczewski, who had laboriously gone over the entire process of separation again and again, till the residue had become colourless, and I had found by previous experiment on pure uric acid that the uric acid was not lost or changed in any way by the process). On evaporating a portion to dryness and heating with nitric acid and adding ammonia, purple murexide was obtained, and the synthesis of uric acid confirmed.

Now came the question of how to isolate the uric acid, and this I found a very difficult matter.

The rationale of Horbaczewski's method is this. The urates and cyanurates of potassium are precipitated as ammonium, magnesium and silver salts. These are decomposed with potassium sulphide, the silver being thus thrown out. The uric and cyanuric acids are precipitated by acid and any sulphur thrown out is dissolved away by bisulphide of carbon. The cyanuric acid is then separated by alcohol and ether and the uric acid remains pure.

Horbaczewski's method does not work well, because in the presence of other matters ammonium chloride and ammonio magnesium and silver solutions do not readily precipitate uric acid, and because the separation of uric acid from cyanuric is not readily effected by alcohol, uric acid, I find, being slightly soluble in even absolute alcohol, and more so in the presence of cyanuric acid.

The methods attempted for effecting this separation were the following:—

To the decolorized solution in potash of the mass obtained as above ammonium chloride was added and the precipitate filtered off. The more insoluble salts were separated from the solution by three successive crystallizations, and the mother liquor, which gave the murexide very clearly, was evaporated to dryness, dissolved in sulphuric acid and precipitated by water, this being a good way of obtaining uric acid in a crystalline form. The resulting crystals were, however, found to be chiefly cyanuric acid, mixed with a few crystals of uric acid, and as the three crops of crystals I had obtained before contained much uric acid, this method of isolating uric acid by crystallization was unsuccessful. Some of these crystals were dissolved in boiling water and evaporated just to dryness with hydrochloric acid. The residue, which contained uric acid, was boiled with successive portions of absolute alcohol. Nearly the whole dissolved, but on testing residue and solution, neither contained any uric acid, showing that it was impossible thus to separate the two acids. Some more of the crystals, which contained uric acid, were dissolved in water; ammonio-sulphate of magnesium and ammonio-chloride of silver were added. The precipitate was filtered off and decomposed with solution of sulphide of potassium. The sulphide of silver was filtered off and the solution acidified with hydrochloric acid and allowed to crystallize. The residue, however, after the removal of the sulphur with CS_2, was found to contain no uric acid, thus showing that silver and magnesia, though precipitating uric acid when present in considerable quantity, will not do so when in small quantities and when salts of other acids largely preponderate.

I have, then, been unsuccessful in materially improving upon Horbaczewski's method for the isolation of uric acid when obtained from glycocine and urea, except in the one point of decolorization of the impure urate solution by animal charcoal.

Turning to the question of the constitution of uric acid, this reaction does not, unfortunately, settle the point. The reaction, indeed, might be represented simply thus—

$$\left\{\begin{matrix} CH_2.NH_2 \\ CO.OH \end{matrix}\right. + 3\,CO\begin{matrix}\diagup NH_2 \\ \diagdown NH_2\end{matrix} = \left\{\begin{matrix} CH_2NH(C_3N_3O) \\ CO.OH \end{matrix}\right. + 3\,NH_3 + 2\,H_2O$$

and uric acid would be glycocine in which a cyanuric acid residue has been inserted, just as hippuric acid is glycocine in which a benzoic acid residue has been inserted:

$$\left\{\begin{matrix} CH_2.NH(C_3N_3O) \\ CO.OH \end{matrix}\right. \qquad \left\{\begin{matrix} CH_2.NH(C_6H_5.CO) \\ CO.OH \end{matrix}\right.$$

And this seems to be possible, for uric acid when heated with hydriodic acid yields glycocine, carbonic acid and ammonia.

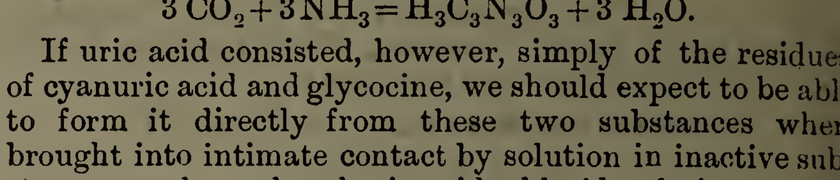
$$C_5H_4N_4O_3 + 5\,H_2O = \left\{\begin{matrix} CH_2.NH_2 \\ COOH \end{matrix}\right. + 3\,CO_2 + 3\,NH_3$$

the carbonic acid and ammonia representing exactly one molecule of cyanuric acid with three of water.

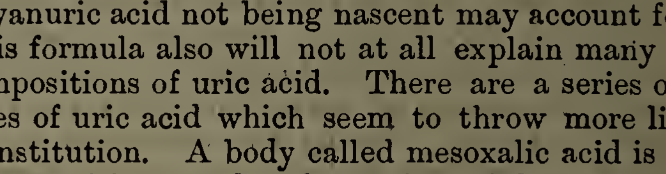
$$3\,CO_2 + 3\,NH_3 = H_3C_3N_3O_3 + 3\,H_2O.$$

If uric acid consisted, however, simply of the residues of cyanuric acid and glycocine, we should expect to be able to form it directly from these two substances when brought into intimate contact by solution in inactive substances, such as phosphoric acid, chloride of zinc or glycerine; this I have not been able to do, but the fact of the cyanuric acid not being nascent may account for this.

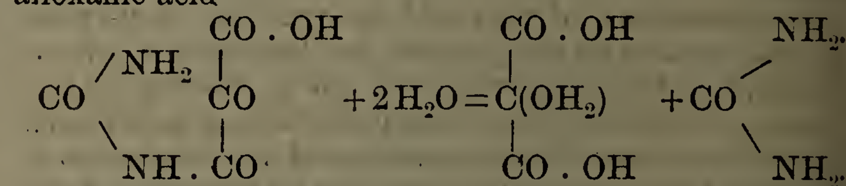
This formula also will not at all explain many of the decompositions of uric acid. There are a series of derivatives of uric acid which seem to throw more light on its constitution. A body called mesoxalic acid is formed together with urea by the action of baryta water on alloxanic acid—



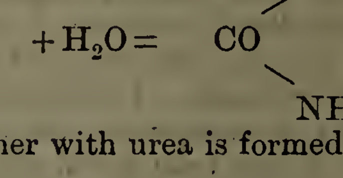
Alloxanic acid is formed by the action of baryta water on alloxan.



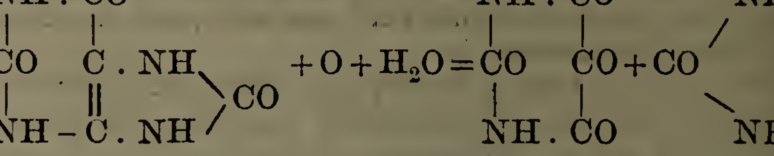
Alloxan together with urea is formed on the oxidation of uric acid.



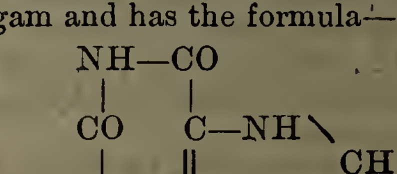
Uric acid, then, is probably built up of a tricarbon nucleus and two urea nuclei. The correctness of this formula is also shown by another class of derivatives of uric acid. Xanthine is obtained from uric acid by reduction with sodium amalgam and has the formula—



Theobromine and caffeine or theine are di- and trimethyl xanthine and have the formulæ—



Finally all these bodies, uric acid, alloxan, xanthine, theobromine and caffeine yield on oxidation with nitric acid and addition of ammonia the purple body known as murexide, an ammonium salt of purpuric acid, having a constitution very analogous to two molecules of alloxan—



From these decompositions it would appear that the urea, not the glycocine, is the important element in the production of uric acid from urea and glycocoll, but what the exact decomposition is, we cannot at present presume to say.

This work has been done in the Laboratories of the Pharmaceutical Society; my thanks are due to Mr. Dunstan for his help and valuable suggestions.

The paper was illustrated by specimens, diagrams and experiments.

A discussion followed, in which the Chairman, Secretary, Messrs. Ranken and Short took part.

Mr. Dymond then took the chair and Mr. H. G. Greenish gave his Report on Pharmacology, "Notes on Nigella Sativa and Nigella Damascena."

The report was followed by a discussion, in which the Chairman, Secretary, Messrs. Lowe and Ranken took part.

The meeting then adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above Association held on the 12th inst., Mr. C. Parkinson, President, in the chair, a paper on "Photography by aid of the Incandescent Electric Lamp," was read by Mr. F. W. Branson.

The commencement of the paper related to the utility of photo-micrography to scientists as an easy and rapid method for obtaining photographic prints of microscopic objects to illustrate papers and as an aid in the production of blocks for book illustration by means of photo-zincography or some allied process. A description of the apparatus was next given. A large four-celled bichromate battery was used, with arrangements for increasing or diminishing the zinc area immersed in the solution, to which latter was added 1 per cent. mercuric sulphate. The lamp used was 2½ candle power, aspecial feature of the lamp being the frosted surface obtained by means of a special varnish, the advantage hereby gained being a strong but diffused and equal illumination in close proximity to the lamp, rendering condensing lenses, when low powers are used, quite unnecessary. A resistance coil of simple construction was included in the circuit to regulate the current and also to switch on the lamp for the requisite number of seconds. The description next related to an ordinary monocular microscope with short and wide tube, the eye-piece being inserted within the flange of a bellows camera, the ground glass of which receives the image of the object it is desired to photograph. A special arrangement of the lamp for use with high powers was also alluded to and shown. The use of the eye-piece for photography was recommended, provided that both eye-piece and objective possessed good optical properties. Objectives must have a flat field, perfect definition and preferably exact coincidence of visual and actinic foci. To determine this the author advised the placing on the microscope stage, in a slightly oblique position to the optical axis, a test plate having parallel lines or markings; the image of the central lines should now be formed, and if these photograph sharply the lens may be noted as a perfect one for photo-micrographic purposes, but if not the differences may easily be measured by means of the fine adjustment and either corrected by means of the addition of a biconvex lens to the objective or the focus may be altered after the visual focus has been obtained to the extent of the difference previously found. It was then stated that transparent objects must be stained before being submitted to the process, such reagents as picro-carmine, which gives non-actinic colours, being most satisfactory. The combined action of light and reducing agents on a sensitive photographic plate next received attention, as did also the manipulations requisite for the production of successful negatives and prints. Lastly, some advantages of the electric lamp were enumerated, the principal being the comparative absence of heat rays, also the very actinic character of the light when considerable battery power is used; the apparatus is, moreover, easy of manipulation. The object photographed before the meeting was a transverse section of echinus spine, a two-inch objective being used with thirty minutes' exposure. The specimens exhibited included some very good photographs, showing early progressive embryonic development of the chicken.

A discussion followed, in which the President, Messrs. Glew, Killick and Leckenby took part.

A vote of thanks to Mr. Branson for his valuable and interesting paper was proposed by Mr. Allen, seconded by Mr. Snow, and carried with acclamation.

Parliamentary and Law Proceedings.

Patent Medicines.

The following is the text of the Bill introduced into the House of Commons by Mr. Warton, the second reading of which is fixed for the 26th inst.:—

A Bill to Restrict the Sale of Patent Medicines.

Whereas patent medicines containing poison have caused sickness and death:

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. From and after the first day of January, one thousand eight hundred and eighty-five, any person claiming to be a proprietor or part proprietor of any patent medicine, and any vendor or purchaser by wholesale or retail of any patent medicine, may require the same to be analysed by the Pharmaceutical Society of Great Britain.

2. If the said Society find on analysis that any patent medicine contains poison, such poison being one of the poisons in Schedule A. of the Pharmacy Act, 1868, or declared to be a poison by the said Society by resolution within the powers contained in the second section of the said Act, then the said Society may from time to time by resolution declare that such patent medicine contains poison; and thereupon the said Society shall submit the said resolution for the approval of the Privy Council, and if such approval be given, then such resolution and approval shall be advertised in the *London Gazette*; and on the expiration of one month from such advertisement, the patent medicine named in such resolution shall be deemed to be a poison within the meaning of the said Act.

3. If the said Society find on analysis that any patent medicine does not contain poison within the meaning of the second section of this Act, the said Society may from time to time by resolution declare that such patent medicine is free from poison; and thereupon the said Society shall submit the said resolution for the approval of the Privy Council, and if such approval be given, then such resolution and approval shall be advertised in the *London Gazette*; and on the expiration of one month from such advertisement, the patent medicine named in such resolution shall be deemed to be free from poison, and any proprietor or vendor thereof may label the box, bottle, vessel, wrapper, or cover in which such patent medicine is contained with the words "free from poison."

4. Any patent medicine shall, unless and until the said Society have analysed the same, be deemed to be a poison within the meaning of the Pharmacy Act, 1868.

5. The sixteenth section of the Pharmacy Act, 1868, shall be read and construed as if the words "nor with the making or dealing in patent medicines" were not contained therein.

6. This Act shall be read and construed with the Pharmacy Act, 1868, and any Act amending the same.

7. This Act shall not extend to Ireland.

Poisoning by Phosphorus Paste.

On Tuesday an inquest was held before the Borough Coroner, Mr. J. C. Malcolm, at Armley Gaol, Leeds, on Bridget Hogan, aged 47, who died at the gaol on Saturday from the effects of taking phosphorus paste on the previous Wednesday, she at the time being under remand on a charge of attempted suicide. The evidence showed that the deceased had been in a low state of mind for some time past. In returning a verdict of "Suicide whilst labouring under temporary insanity," the jury desired the Coroner to call the attention of the Home Secretary to the dangerous nature of Steiner's Phosphorus Paste, used for the destruction of vermin, and the facilities offered for obtaining that preparation for unlawful purposes.—*Leeds Express.*

MYSTERIOUS CASE OF POISONING BY STRYCHNIA.

On Tuesday, Dr. Housely, district coroner for Retford, resumed an inquiry which had been adjourned from the 17th of last month at Warsop, near Mansfield, as to the death of Hannah Head, a girl, ten years of age, who had died on the 16th of February from having taken Epsom salts, supposed to have contained strychnia.

The following evidence was taken:—

Mr. G. Stein, surgeon of Warsop, said that on Monday, February 18, he made a *post-mortem* examination of the deceased. The body was very thin. The hands were clenched, the fingers being drawn into the palms of the hands. The feet were clubbed, the soles being arched. There was lividity about the lips. The expression of the countenance was natural. On opening the body he found the right cavity of the heart to contain blood, which was fluid and dark. After the *post-mortem* he was not able to state positively the cause of death, and considered an analysis necessary. The symptoms were consistent with poisoning by strychnia. Witness placed the stomach and its contents into a jar, which was sealed and given to Police-constable Stevenson on February 18. The symptoms somewhat resembled tetanus, which was a spasm of the muscles. On Saturday night, February 16, witness received a packet said to contain Epsom salts.

Police-constable Stevenson, stationed at Warsop, said he received from Dr. Stein the packet said to contain salts, on Monday, February 18, and a jar containing the stomach of the deceased. The jar was sealed. These together with a small bottle of toothache tincture he delivered to Dr. Truman, of Nottingham.

Dr. Edgar Beckit Truman, of Nottingham, county analyst, said that on February 20, he received from the last witness three articles—a white jar sealed and unbroken, a blue paper containing what was said to be Epsom salts, and a bottle of toothache tincture. The jar contained the stomach, which weighed thirteen and a half ounces. There was no diseased appearance about the coating of the stomach. The contents amounted to eight and a quarter ounces and consisted of a brown fluid with an acid reaction and some animal flesh, probably ham fat, and potatoes. Witness took half of the stomach and half of the contents and submitted them to analysis. He found evidence of the presence of sulphate of magnesia, commonly called Epsom salts, and also of strychnia. The strychnia obtained from the stomach gave the usual reaction. Witness examined the remainder of the stomach for poisons with a negative result. He next examined the salts of which the packet produced was the residue. There were 355 grains of it. He found that in a teaspoonful levelled there were 52½ grains, but tested it for mineral poisons with a negative result and also for oxalic acid, of which there was also none. Strychnia was present in varying amounts, on an average 3 per cent. In a teaspoonful there would be about a grain and a half. The small bottle simply contained a solution of camphor and chloroform.

The Coroner: If a child lived four hours after taking strychnia would a much larger quantity have been taken than you found in the stomach?

Dr. Truman: If the child had died sooner more strychnia would have been found. Half a grain has been known to produce death.

Does strychnia undergo any change in the stomach?—No.

How much strychnia would it require to kill a child ten years old?—I should think a quarter of a grain would be a fatal dose.

How soon do the symptoms commence?—They may commence in a few minutes, but usually half an hour elapses.

How long does a person usually live after taking a poisonous dose?—About four hours only.

By a Juror: There was no colouring matter in the salts. It was alkaloid strychnia, and would take some time before undergoing the change by solution. That would account for the time the child lived. After hearing the evidence of the father of the deceased witness was of opinion that the cause of death was strychnia poisoning. The symptoms mentioned by the father in the child on the preceding Friday arose from strychnia poisoning.

Elizabeth Head, stepmother of the deceased, stated that the first lot of strychnia she bought was from Mr. Potts's shop, Mansfield, a year and a half ago. She bought a shilling's worth, and this was used in a short time for the purpose of poisoning rats. Subsequently witness took the empty bottle to Mr. Wood's, and purchased another shilling's worth of strychnia. If she had been twice to Mr. Potts's shop, she believed she took the same bottle. Afterwards witness's husband said, "There, I have made an end of all," meaning, as witness supposed, that he had thrown the strychnia into the fire. Witness had not bought strychnia at any other place, and had not known her husband to bring any into the house. Witness was in the house when her husband told the deceased child to fetch the salts. She bought two ounces. It never occurred to witness to throw away the salts after the child had the first twitchings, on the Friday. She could not say where her husband kept the strychnia. No person in the house had the same symptoms as the child after taking the salts. The child's life was insured, but in what society she did not know. They had not received the insurance money. The child had been insured between two and three years.

By a Juror: The strychnia was purchased each time at the request of her husband. The salts were purchased about five o'clock, and placed in the cupboard. In the evening, about eight o'clock, a dose was administered to the deceased.

William Head said he believed that he told the deceased to bring two ounces of salts from Mr. Tyler's shop. It never occurred to witness to connect the child's illness with the taking of the salts. After the purchase of the last lot of strychnia the bottle was thrown by witness into the stream. None of the family had similar symptoms to the deceased after taking the salts. The packet from which he took the salts to give the deceased had the appearance of not having been previously opened. All witness's children were insured. The strychnia had been bought by witness's wife at his request.

Sarah Ann Bean, a married woman, residing near to the deceased's parents, said from what she had seen the child had been kindly treated. Witness went to Mr. Head's house on February 16, when deceased was ill, and was present when she died.

Ann Stevenson, the wife of Police-constable Stevenson, said that early in January she sent for some salts—two ounces—from the shop of Mr. Bloor. Witness took some herself and did not perceive any ill effects. About a week after witness gave some to her daughter and about an hour after she complained of her legs. These symptoms were exhibited on taking a second dose two days after. The child also experienced twitchings. On hearing that Mr. Head's child was ill she threw the remainder of the salts into the fire.

Betsy Ann Crossland, of Warsop, deposed to being attacked by twitchings in the arms and legs after taking a dose of salts purchased at Mr. Bloor's shop.

George Tyler, chemist and druggist, of Warsop, was next called. After being cautioned by the Coroner, he should, he said, prefer to give evidence. He said he was not registered as a chemist under the Pharmacy Act, 1868. He sold Epsom salts, weighing them into packets. He remembered the deceased coming to his shop on the first Friday in January for salts, but supplied her with a two ounce packet, which was labelled bearing the name of John Bloor. Witness was the manager to Mr. Bloor, and had been in that position from eleven to twelve years. All the labels bore Bloor's name. Witness did not keep strychnia in the shop, but occasionally got it from Mr. Bloor's other shop at Mansfield Woodhouse for making a solution from the British Pharmacopœia, but had never kept strychnia in stock. The bulk of Epsom salts from which witness supplied the deceased were obtained from Messrs. Barron, Harvey and Co., London. It was impossible for the salts to become mixed with strychnia.

The Coroner, then, addressing the jury, said if they thought any practical purpose would be served by keeping the inquiry open they would again adjourn, but if they were satisfied with the evidence before them, he would sum up. The jury intimated that it was impossible to carry the inquiry further, and the Coroner at great length carefully reviewed the evidence given by the witnesses. He said he need not tell them that that was a remarkable and mysterious case. The inquiry was first as to the cause of death, and as to that he did not think they would have any difficulty. They had been told that the symptoms the child exhibited were consistent with strychnine poisoning, and the analysis confirmed that supposition. The next question for them to decide was how that strychnia became mixed with the salts, and then whether it was administered wilfully or not. If these questions could not be satisfactorily answered it would be better to return an open verdict simply specifying the cause of of death, and leaving the questions as to how the strychnia became mixed with the salts, and whether it was wilfully administered or not, open.

The Jury, after about a quarter of an hour's deliberation, returned a verdict to the effect that death was attributable to strychnine poisoning, there being no evidence to show how it became mixed with the salts.—*Nottingham Journal.*

Reviews.

A Manual of Chemistry. By Henry Watts, B.A., F.R.S. Vol. I. Physical and Inorganic Chemistry. Thirteenth Edition of Fownes' Chemistry.*

When a book has reached, as this one has, the thirteenth edition, it may fairly be considered as outside the range of general criticism. Neither need we with this book and in this Journal stop to give an account of its contents, for, it is to be remembered, the work originally emanated from the Professor of Chemistry to the Pharmaceutical Society, Mr. Fownes, and ever since its first appearance has been the standard text-book on chemistry for pharmaceutical students. The hand of Mr. Watts, who has edited the later editions of the work, is and has been prominent in the best sense, and this in many ways. One of the most important, perhaps the most important, way in which Mr. Watts's admirable editing is exemplified is in the definite and consistent system of nomenclature which is adopted and logically developed throughout the volume. Indeed, Mr. Watts's salutary efforts in this direction are well known and by no means restricted to the present case, but are also noticeable in his editing of the *Journal of the Chemical Society* and in many other literary undertakings with which he is associated. For the chemical student nothing is at once more important and necessary than that he should be unhampered and unfettered in his work by an illogical and arbitrary nomenclature. This, unfortunately, is too seldom the case in the majority of chemical manuals, where there is often more evidence of loose writing than of sound thinking, and where it is customary to sacrifice exactness in this respect to profuseness and even to prolixity in details which are often in themselves relatively unimportant. The anomaly reaches its height and is much more acutely felt in organic chemistry. Nothing is more fatal than this to the progress of the true student who seeks to find a connected and orderly sequence of facts designated by a correspondingly connected and orderly series of names. Accuracy, simplicity and consistency in nomenclature must for ever be one of the first canons in scientific criticism. True progress in chemistry, as in everything else, consists, at bottom, in the development of order, and until this has been attained, especially in chemical nomenclature, the eminent German physiologist and logician who lately affirmed that "chemists are at strained relations with logic and grammar" will remain unanswered—because unanswerable. But to return to the volume before us. The first section, which relates to chemical physics, has been very well brought up to date and the same may be said of the bulk of the volume; in fact the work is still in every respect worthy of the greatest confidence, and no doubt will retain its high place as a standard text-book for pharmaceutical students. At a time when crowds of typographical errors and altogether inexcusably careless mistakes stand naked and unashamed, and are even winked at by critics, in one of our great treatises on chemistry, it should be a compliment to the author of a less ambitious work to say that it is peculiarly free from such offences against literary decency. On p. 265 the "Cl_2," which is stated to be formed when Si_2C_2N is oxidized, should obviously be CO_2. "Octahedrons" (p. 409) is an innovation that perhaps is defensible. A little consistency might with advantage be observed in naming authors; thus we read on the one hand of "Dr. Frankland," "Dr. Odling," "Dr. Gladstone," etc., and on the other of "Crookes," "Roscoe," "Joule," "Tyndall," etc. The diæresis upon the "i" in "haloïd" and in "alkaloïd" seems of doubtful necessity.

A Short Manual for Monthly Nurses. By Charles J. Cullingworth, M.D., etc.*

This little book is said to owe its existence to a regret expressed that the author's 'Manual of Nursing' did not deal with the subject of obstetric nursing. However this may be, we have no doubt that it is capable of being extremely useful, not only to the class for whom it is ostensibly written, but for others who from force of circumstances may have to undertake similar duties more or less involuntarily. The text is clearly written, without obscurations due to technical expressions, and whilst affording valuable information as to the best course to be taken under certain emergencies, it affords no encouragement to the nurse to step outside her proper sphere.

THE PHARMACEUTICAL SOCIETY.

Sir,—Mr. Hart seems to have made up a man of straw for the sole purpose of knocking him down. I have never said that "The Pharmaceutical Society was not entitled to the slightest share of our gratitude;"—on the contrary I have constantly asserted that had it not been for the Society, the chemists and druggists would have been in a very different position from what they now are. But for all that I do not see that I am bound to fall down and worship the Council, or to say that everything it may say or do is the only proper thing to have said or done. There have been times when resistance to the propositions of the Council was essential to the liberty of the trade, and I think there are very few now who are sorry that the resistance was effectual.

I cannot see why Mr. Hart should drag the Benevolent Fund into the question; no doubt the relief of distressed members of the trade is a praiseworthy object, but I do not conceive that the Society exists only for that. Nor do I think nor have I ever said "that one of the principal reasons why the Council exists is to see that pharmacists are not summoned on juries." What I did say on that head, and what I still contend, is, that if a pharmacist is summoned on a coroner's jury and is threatened by the coroner with a fine in the event of his refusing to attend, the Council ought to take up the case and if necessary defend it in a court of law, and that they ought to let it be known that they will do so. Individual effort is very essential to the success of any cause, but individuals can hardly be expected to fight the battle of the whole Society at their own sole costs and charges.

I am at a loss to understand Mr. Hart's remarks about Local Secretaries and Local Committees, for I do not know of any to whom they apply; but as Local Secretaries are chosen by the members of the Pharmaceutical Society, and Local Committees by the members of their respective Associations, I suppose the electors have chosen those whom they consider the most suitable men.

It seems, however, after all, that Mr. Hart is not altogether satisfied with the policy of the Council, but has his own special grievance, and wishes it to adopt a more vigorous course in that particular direction, forgetting apparently that neither the Pharmaceutical Council nor any other Council has the slightest right to interfere with any man's trade in this country, so loug as he is not acting illegally.

To those writers who are either ashamed of their productions or afraid to acknowledge them, but under the convenient shelter of a fictitious signature indulge in statements they cannot justify, I make no reply; but would suggest that if any such persons know of people trading illegally, their time would be more profitably employed in furnishing the Registrar of the Society with evidence to enable him to prosecute.

Cheetham Hill. W. WILKINSON.

THE POSITION OF PHARMACY.

Sir,—That the position of pharmacy in this country at the present time is in a very unsatisfactory condition it would, I think, be idle to attempt to deny. The mass of evidence in proof of this assertion collected with such commendable energy by Professor Attfield, from various parts of the country, is simply overwhelming. Complaints of competition by unqualified traders reach us from every part, and murmurs, loud and long continued, against the inaction of the Pharmaceutical Society are heard on every hand. Nay, it is no uncommon thing to hear those whose want of business capacity is a conspicuous cause of their failure to earn a livelihood, lay the blame of their non-success upon the Pharmaceutical Society.

Competition from unqualified traders does not date from yesterday. From time immemorial, salts, senna, sweet spirits of nitre, syrup of rhubarb, tincture of rhubarb, and numerous other drugs and pharmaceutical preparations have been vended by grocers, hucksters, etc., etc., until they have acquired a kind of prescriptive right to the sale of them. Those of us who are anxiously waiting for any legislative enactment which shall restrict the sale of these articles to the qualified pharmacist, will, in my opinion, be doomed to sure disappointment. Moreover, the supply of drugs, etc., to these men will continue, and, however distasteful it may be to us, as qualified pharmacists, we may occasionally find ourselves so situated that out of pure self-defence we have no alternative left but that of supplying these men ourselves. Those of our members who have the fortune to reside in this neighbourhood will, I think, readily understand my meaning.

Our success as pharmacists will not be brought about by any Act of Parliament, but by our own individual effort, by taking care to place the stamp of individuality upon our business, by trying so to win the confidence of our customers that we need fear no competition either from stores or hucksters, always remembering that the calling of a pharmacist is after all quite as much a business as a profession.

72, Lancashire Hill, Stockport. THOMAS HART.

Junior.—If the father is alive, and the business belongs to him, the course would be legal.

Mr. J. P. Henry is thanked for his communication.

W. Robinson.—(1) You will find the sum properly acknowledged, *sub* "Newthorpe," p. 692, col. i. (2) See a paper on bleaching sponges, before, p. 88. (3) Tome's 'Dental Surgery.'

J. Richards.—See under "Succus Glycyrrhizæ" in 'Pharmacographia.'

H. C. H.—*Chrysosplenium oppositifolium.*

A. E. I.—The careful generation of chlorine would be sufficient for the purpose.

"*Rumex.*"—We think the form of the circular and the reputed action of one of the ingredients would suggest the wisdom of not making the experiment except under medical advice.

G. C.—To meet the views of particular prescribers the preparation is sometimes made of a gelatinous consistence by the use of soft soap.

H. B.—Hydrargyri oxid. rubrum.

J. Hardy.—We are unable to go beyond the official report in the publication of correspondence addressed to the body in question.

H. Shaw.—(1) Clinical experiments made by Mr. Ashburton Thompson appeared to show that amorphous phosphorus, free from normal phosphorus, is inert in the human system (*Pharm. Journ.*, [3], vi., 41). (2) Glycerine of tragacanth.

J. H. S.—Glycerine of tragacanth. You are recommended to consult the prescriber as to whether powders were not intended.

Student.—The object of the examination is, to quote the words of the Calendar, "to ascertain that the candidate has such an amount of ability, and made such use of it in the acquirement of elementary knowledge, as to justify the expectation of his proving a successful student." You will see therefore that we are unable to mention any one book that would enable you to prepare yourself for the competition.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Pickering, Van Eeden, Symes, Turner, Smith and Co., Scott, Richards, Inquirers, Anon.

"THE MONTH."

Mercurous tannate, the use of which was recently mentioned as having been recommended, appears to be attracting attention and is reported to have been tried in a South German university clinic in the treatment of syphilis with good results, whilst it was well tolerated by the patients (*Pharm. Zeit.*, March 8). The compound is said to be prepared by the precipitation of a solution of mercurous nitrate with potassium tannate and careful washing of the precipitate. In another journal (*Archiv*, March, p. 207) mercurous tannate is described as an odourless, tasteless, dark green powder containing about 50 per cent. of mercury. It is said not to be materially attacked by acids and not generally soluble without decomposition. Very dilute caustic and carbonated alkalies cause the separation of a slime consisting of mercury in such a minute state of division that when examined under the microscope the particles exhibit the phenomenon known as molecular movement. It is administered internally in doses of one decigram two or three times daily, and notwithstanding the comparative largeness of the dose it is said not to cause any disagreeable symptoms in the stomach or bowels. It appears to be rapidly absorbed into the system, being found in the urine twenty-four hours after administration.

Professor Eulenburg has communicated some information as to his method of treating neuralgia with osmic acid (*Pharm. Zeit.*, March 5). A one per cent. solution of the osmic acid crystals in distilled water is used and this should be kept in well closed bottles protected from the light. Notwithstanding this precaution the solution after a time darkens gradually and a dark, almost blackish, separation takes place, so that it is advisable to prepare only small quantities at a time. The darkened solution can however be used without disadvantage. The dose injected is usually 0·005 gram (=0·5 of the solution); in exceptional cases 0·01 gram (=1·0 of the solution) has been administered, but even this quantity produces no local or general disturbance. It is rather surprising that this pungent acid (resembling chlorine), which has a strongly irritating action on the outer cuticle, should cause so little pain when injected subcutaneously and scarcely produce any apparent change in the skin or tissue beneath it. At the most there is, as a rule, only a slight reddening or possibly an insignificant swelling in the neighbourhood of the puncture, but this quickly disappears. Sometimes the puncture may become blackened by the extrusion of a drop of the acid, but this has not been observed to cause any local inconvenience.

According to a note in the *Wiener med. Blatt.* (*Pharm. Centralh.*, March 13), the most suitable form for the administration of paraldehyd is an emulsion. The method and proportions recommended for the emulsion of 18 grams of paraldehyd are to rub an equal weight of powdered gum into a thick mucilage with a little water, then add a little paraldehyd, and after rubbing this to a homogeneous mass to pour in, in small portions alternately, the paraldehyd and sufficient water to bring the emulsion up to 150 grams; to this, add 30 grams of syrup. amygd. Dose, two tablespoonfuls. Each tablespoonful will contain about 1½ gram of paraldehyd; and should 3 grams not produce the desired effect, a second dose may be given half an hour after the first.

From experiments made on rabbits, it would appear, according to some details furnished by M. Baumetz to the Société de Thérapeutique, that there exists pronounced antagonism between paraldehyd and strychnia. Enough strychnia to kill twenty-five rabbits was given to one of these animals, to which a large dose of paraldehyd had previously been administered, without producing death, the only symptom of the action of strychnine being a few weak convulsions. Experiments on other animals gave the same results (*Medical Press*, March 12, p. 232).

Peroxide of hydrogen is recommended in the March number of the *Practitioner* (p. 197) as a local antiseptic and astringent. The advantages which are claimed for it are that, besides being a powerful antiseptic, it is colourless, odourless, cleansing and stimulating, does not stain or corrode, destroys pus, causes no pain in its application and is not poisonous. In purulent ophthalmia, otorrhœa, gonorrhœa, leucorrhœa, ozœna and stomatitis it has been found useful, and in all forms of ulcer, especially if of syphilitic origin, it exerts a healing effect. Dr. Shelly points out that if a few drops of the ordinary 10 per cent. solution be brought in contact with pus, a brisk effervescence at once commences and continues until all the pus is completely destroyed and a stimulant action on the wound takes place, followed by healthy repair. He suggests its use as a topical application in membranous diphtheria.

Writing respecting the use of "sulphide of calcium" solution for the cure of scabies, referred to last month (see before, p. 664), Mr. Wilkinson, of Manchester, says:—"I do not know whether it is supposed to be a new method of treatment or not, but I made the very same solution five and twenty years ago for a medical man in this neighbourhood, who found it a very effectual remedy for the itch, though I think somewhat severe. His treatment was to wash the skin thoroughly with warm soap and water, then rub the lotion well in before the fire, and afterwards again wash with soap and water."

The pharmacology of the camphor group is being investigated by Dr. Pellacani, of Modena. He reports (*Arch. f. exp. Path.*, xvii., 369) that borneol and menthol in respect to the manner of their action upon the nerve system differ essentially from other members of the camphor group. Like common camphor they act chiefly upon the central organs of the nervous system, especially the spinal cord and medulla oblongata, but it is in the direction of a diminution of their sensibility and activity, and on account of this dispressing action they are thought much more suitable for administration as a calmative. Menthol especially was found to be innocuous to the vascular system and large doses of it were tolerated by animals. Brom-camphor in its physiological action showed no specific distinction from common camphor, but it acted much more powerfully upon dogs, affecting them in doses in which ordinary camphor was quite inert. Some experiments have been made with secondary alcohols derived from decomposition products of camphors in the organism. One of these, campherol, prepared by the action of hydrochloric or sulphuric acid upon campho-glycuronic acid, occurring in the urine after the ingestion of ordinary camphor, was found to manifest in small doses administered subcutaneously an action similar to that of the camphor in large doses, together with a stimulating effect upon the heart.

The demand for eucalyptus oil and eucalyptol, based on the reputation of the products obtained from the leaves of *Eucalyptus Globulus*, has brought into commerce oils obtained from other species, which are said not to possess the same medicinal properties. However this may be, as there is a difference in their money value, it may be useful to quote from Messrs. E. Merck's circular the characters in which an oil that appears to be known in the German market as "Oleum Eucalypti australe" differs from the genuine product from *E. globulus* leaves. The genuine oil has a weak dextro-rotatory action, forms a clear solution in 90 per cent. alcohol in all proportions, does not puff when treated with iodine, turns yellowish in contact with sodium, and has a specific gravity of from 0·900 to 0·925, according as it is distilled from old or fresh leaves. The "australe" oil is strongly lævo-rotatory, only slightly soluble in 90 per cent. alcohol, puffs with iodine, is coloured red on standing with sodium, and has a specific gravity not higher than 0·860 to 0·870. The characters for *E. Globulus oil* answer for eucalyptol. The "eucalyptol puriss." has a boiling point between 170° and 173° C., a specific gravity of 0·910 to 0·920 at 15° C., and is as clear as water.

The vesicating substance obtained from the root of *Thapsia gargonica*, which is in France largely used for the preparation of plasters (see *Pharm. Journ.*, [3], ix., 143), has been submitted to an examination by F. Canzoneri, who reports (*Gazz. Chim.*, xiii., 514), that he has separated from it normal caprylic acid and two other new compounds. One of these, occurring in very small proportions, is non-nitrogenous, crystallizes in scales melting at 87° C., and in solution has a vesicating action. The other is a bibasic acid, which he has named "thapsianic acid" and represents by the formula $C_{16}H_{30}O_4$. It crystallizes from alcohol in shining scales melting at 123–124° C., and is obtained as a crystalline potassium salt upon treating the ethereal extract of the root with strong potash ley.

The artificial preparation of heliotropin (piperonal) was referred to in this Journal in connection with the Vienna exhibition. According to the *Chemiker Zeitung* (Feb. 7), the starting point is white pepper, from which the piperin is removed by extraction with alcohol, and converted into piperinate of potassium by heating it at a water-bath temperature for twenty-four hours with an equal weight of potassium hydrate and five or six parts of alcohol in a roomy retort provided with a vertical condenser. Upon cooling, the piperinate of potassium separates in shining yellowish scales, which are washed with cold alcohol, recrystallized from hot water, and when necessary decolorized by animal charcoal. The piperinate of potassium is thus obtained in nearly colourless wart-like groups of crystals, which become yellow under the influence of light. One part of this product is dissolved in forty to fifty parts of hot water, and into the hot liquid a solution of two parts of potassium permanganate is poured under continual stirring. A pasty mass is formed, which is drained and washed with hot water as long as it retains the characteristic odour of heliotropin. The united liquids are then submitted to distillation over an open fire, and from the distillate—which is fractionated because the first runnings are richest—the greater part of the piperonal separates after cooling and standing in the crystalline form; the remainder may be recovered by shaking the liquor with ether.

It was mentioned recently that Herr Ladenburg had succeeded in obtaining piperidine synthetically by treating pyridine with sodium in alcoholic solution, but the yield was at first not satisfactory. He now reports (*Berichte*, xvii., 389) that by a slight modification of the process better results have been obtained. A larger quantity of the base has been prepared so as to allow of its exact comparison with piperidine derived from piperine, and it is stated that at present the two products appear to be identical. Herr Ladenburg has also prepared in a similar way homologues of piperidine from methylpyridines and ethylpyridines derived from bone oil. One of these, γ-ethylpiperidine, has an odour resembling coniine and piperidine, which appears to confirm Professor Hofmann's opinion that coniine may be a homologue of piperidine, and for this reason the result of the investigation of propylpiperidine, with which Herr Ladenburg is now occupied, is looked for with interest. Moreover, this work will also probably remove any doubt as the nature of tropidine, the nucleus common to several Solanaceous alkaloids (*Pharm. Journ.*, [3], xii., 1049).

The occurrence of a ptomaine presenting a close resemblance to picrotoxin in its physical appearance and chemical reactions has been chronicled by Professor Giacomelli (*Zeit. œst. Apot.-Ver.*, March 1). The only reaction in which the two bodies appeared to differ was that when dissolved in water and a few drops of neutral acetate of lead solution added, upon boiling the mixture, the ptomaine remained unaltered, whilst the picrotoxin yielded a black precipitate, leaving the supernatant liquid colourless. They differed, however, entirely in physiological action. It will be remembered that the discovery of a similar body in beer some time ago, gave rise at first to the suspicion that cocculus indicus had been used, but afterwards its origin was attributed to alteration of albumenoid substances normally present in the liquor.

In fatal cases of poisoning by arsenic a yellow substance has frequently been found at periods varying from a few months to three years after interment of the body, and this colour has generally been taken for granted to be due to sulphide of arsenic. In some recent investigations as to the nature of the substance, by Dr. J. Campbell Brown and Mr. E. Davies, it has been found that the yellow pigment removed from the intestines and stomach contained no appreciable quantity of arsenic, but was readily soluble in chloroform, less so in alcohol, slightly soluble in strong ammonia, and reprecipitable by hydrochloric acid, and insoluble in water. The yellow residue obtained from the chloroform solution was reddened by strong hydrochloric acid, while nascent hydrogen from zinc and hydrochloric acid discharged the colour and dissolved the residue. Nitric acid converted it into a purple, then red, then brown substance; sulphuric acid gave a temporary red colour passing into brown. Sulphuric acid and pure sugar gave the violet-purple tint characteristic of Pettenkofer's test (*Brit. Med. Journ.*, March 15, p. 506).

In a communication to a recently-issued volume of 'Guy's Hospital Reports,' Dr. Stevenson alludes to a generally accepted opinion that water stored in zinc or zinc-coated tanks is not affected by the zinc to any appreciable extent, and states that he has abundant evidence that water does, under certain conditions, act energetically upon zinc and galvanized iron. He mentions a case in which rain water passing from a reservoir through galvanized pipes was for many weeks turbid and milky in appearance, and contained a notable quantity of zinc in suspension and some in solution. The experience is confirmed by Mr. J.L. Wills, who in a letter to the *Chemical News* (Feb. 29, p. 103), states that having left about two litres of water standing during three weeks in a galvanized iron bucket he observed an abundant white flocculent precipitate, which, collected and dried at 100° C., weighed 3·25 grams, and consisted of an oxidized product of zinc.

Confirmation has been received of the report, referred to on a previous occasion, that the German Cholera Commission has succeeded in establishing a connection between the bacillus which had hitherto been found only in the bodies or evacuations of cholera patients and suspected water. According to a correspondent of the *Daily News* (March 26), whilst the Commission was in Calcutta a sporadic outbreak of cholera of great intensity occurred in the native quarter of the city and in the neighbourhood of a dirty tank. Upon examining water from this tank Dr. Koch and his colleagues found that it swarmed with the parasite which they had previously found associated so closely with the disease. It was ascertained that the water had been used both for drinking and bathing purposes by the people among whom the outbreak occurred, and moreover it was observed that coincidently with the subsidence of the outbreak the water became clear of the parasite. Hitherto, however, the members of the Commission have failed to demonstrate the causal activity of this bacillus by communicating through it the disease to animals; but an announcement is now made that Dr. Richards, civil surgeon of Golundo, has succeeded in communicating in this way what he believes to have been genuine cholera to a pig, which died three hours after the cholera poison had been administered.

According to a note in the *British Medical Journal* (March 8, p. 476) Dr. E. Klein has recently investigated the bacillus of jequirity, and finds that the bacillus is, of itself, quite incapable of producing ophthalmia, and, further, that the pus from a case of ophthalmia contained no trace of the bacillus. He found also that the infusion of jequirity could be rendered incapable of producing ophthalmia by boiling for a time insufficient to destroy the bacilli, and that the bacilli, when cultivated in peptone solution or jequirity infusion previously sterilized by boiling for half an hour, possessed no power of producing ophthalmia. The active principle of the jequirity appears, therefore, to resemble, to some extent, in its vital properties the pepsine ferment, in that it is easily destroyed by heat. This statement is confirmed by Mr. Arthur Benson in a subsequent number of the same Journal (p. 564), in which it is stated that he has found that ophthalmia could be produced by the freshly powdered seeds, by the freshly made infusion, by the infusion after bacilli had appeared in it, by the infusion, six weeks old, swarming with various micro-organisms, and by the infusion after the bacilli had ceased all motion and had sunk to the bottom of the liquid apparently dead. He had examined, at all stages of the disease, the discharges and membranes from eyes affected with jequirity ophthalmia without ever seeing the typical bacillus. A one in ten thousand solution of corrosive sublimate prevented bacilli from forming, but did not destroy the power of the infusion to produce ophthalmia.

Dr. Klein, in an article in the *Practitioner* (p. 185), on "Micro-organisms and Disease," states that he finds a mixture of agar agar or Japan isinglass and peptone sugar solution one of the best media for cultivating bacilli, as it is solid, beautifully limpid and an excellent nourishing material. He speaks as though agar agar and Japanese isinglass were identical; the former name is, however, given to *Eucheuma spinosa*, and a jelly obtained from it, while the Japanese isinglass is prepared chiefly, if not entirely, from another alga, *Gelidium spinosum*. Of Japanese isinglass there are several varieties, but the one used by Dr. Klein is in the shape of thin shrivelled transparent lamellæ or narrow bands, and is, he says, very difficult to obtain. The isinglass is soaked overnight in distilled water, 1 to 5 or 6, and then dissolved in a water-bath, well neutralized with carbonate of sodium, filtered and mixed with a third of its bulk of broth, peptone or beef extract solution. As a rule he prefers peptone and sugar solution containing 2 per cent. of beef peptone and 1 per cent. of cane sugar, the solution being neutralized and filtered before use.

The use of tin vessels in the preparation of syrup of violets, on the ground that a preparation having a finer blue colour is thus obtained, has not yet been satisfactorily explained. It has been recently suggested (*Pharm. Post*, March 8) that the tin acts upon the colouring matter of the violets similarly as it is known to do towards other colouring matters, combining with it to form a lake, and that it is to such a compound that a syrup of violets prepared in a tin vessel owes its comparative permanence of colour.

Herr Tschirch has published (*Pharm. Zeitung*, Mar. 15) the results of an examination made to determine the responsibility as to a parcel of vanilla which had been rejected on account of its defective appearance. In the first place the capsules were disfigured by rows of roundish or oval warts. These, upon closer examination, were found to surround minute punctures, which were concluded to have been the work of an insect before the ripening of the fruit. There was also a large quantity of dust and yellow threads, which under the microscope were resolved into the gonidia and mycelium of *Aspergillus glaucus*. In addition, live and dead mites of a species of *Tyroglyphus* were found. The presence of the fungus and mites was attributed to putrefaction, due to the pods being packed before they were sufficiently dry. It was considered, therefore, that all the defects originated before the vanilla left the Mauritius, and the award was made accordingly.

At a recent Pharmaceutical Meeting in Philadelphia, Professor Maisch alluded to the fact that the *Spigelia* commonly sold twenty-five years ago has entirely disappeared from the market, its place having been taken by the much smaller roots of *Spigelia marilandica*, and by one or more species of *Phlox*, principally *P. Carolina*. He had been informed, when in Georgia, that the reputation of *Spigelia* had been built up on the results obtained by the use of *Phlox*. Dr. Miller corroborated the statement concerning *Phlox*, saying that he had found it useful in his own family before he had made extract from it for the trade. On the lists of some dealers both true and false pink root are quoted. Professor Maisch believed that different species of *Phlox* as well as *Spigelia marilandica* were known in the Southern States as Carolina pink, and it was possible that the root of *Phlox* might have been first used and the *Spigelia marilandica* subsequently taken its place (*Amer. Journ. Pharm.*, December, p. 631).

Professor Maisch has also pointed out that the root of *Nyssa grandidentata* is the species which is used under the name of tupelo for making tents, its wood being extremly light, while that of *Nyssa multiflora* and *uniflora*, growing in the Northern States, have a denser wood unsuited for the purpose (*Amer. Journ. Pharm.*, December, p. 632).

Those members of the community whose hobby is botany or natural history will be grateful to Professor Bryce for introducing into Parliament his Bill "to secure access to mountains and moorlands in Scotland." The Bill embodies every possible precaution against the abuse of the access wished for, and it may be hoped that the natural history societies and field clubs all over the country will use every available means to obtain for the Bill Parliamentary sanction. In many parts of the country the localities for rare plants, which are often among the most beautiful scenery of the country, are thrown open by their owners on certain days of the week, and the advantage is rarely abused and much appreciated. Still there are many places in this country and still more in Scotland, the botany of which has been very imperfectly explored, owing to the churlish refusal of the owners to admit persons, even of equal social rank with themselves, to explore their woods and uncultivated lands.

Several medicinal plants are now in bloom. In the country the tops of the elm trees may be seen to be brown with blossoms. On railway banks and waste clayey places the golden blossoms of the coltsfoot are brightening the almost bare soil. The sweet scented green flowers of the *Daphne Laureola* and the purplish ones of the *Daphne mezereum* are now in full bloom. In gardens the rosemary is in blossom, and the *Asarabacca* is just pushing its leaves through the ground. At Kew the *Atropaceæ* are represented by the *Hyoscyamus orientalis*, a valuable plant for botanic gardens, since it flowers at a time when it is difficult to procure specimens of that natural order. At the Royal Botanic Gardens at Regent's Park the Coca plant is now in full bloom. Among our rarer wild plants *Lathræa squamaria* is now emerging from the ground, and its white scape is so unlike any other plant met with at this time of year that it can hardly be overlooked. Further, Mr. Lynch, of the Cambridge Botanic Garden, sends word that the pretty *Muscari racemosum* and *Anemone Pulsatilla*, which grow wild near Cambridge, are now coming into blossom. At the time of writing, a specimen of *Salex Capræa* with several stamens on a female spike has been brought in from Epping Forest, an occurrence which seems to be very rare.

Another new British plant, *Juncus tenuis*, Willd., has recently been detected at Cradley, in Herefordshire, by Mr. R. F. Towndrow. According to a short note in the *Journal of Botany* (p. 91), the plant is interesting as being probably identical with a plant found by Mr. G. Don, in 1795 or 1796, by the side of a rivulet in marshy ground among the mountains of Angusshire, but very rare; it was described at the time in 'English Botany,' 1st ed., as *Juncus gracilis*, and figured under the name of *J. Gesneri*, DC., and in the second edition figured as *J. Gesneri*, while *J. gracilis* and *J. tenuis* are given as synonyms. The rare little plant, *Erythræa capitata*, var. *sphærocephala*, has also been detected by Mr. W. Matthews, in Guernsey, probably on L'Ancresse Common.

According to a note in the *British Medical Journal* (March 1, p. 428), Professor Virchow recently exhibited at a meeting of the Berlin Medical Society photographs of a gigantic plane tree growing in the Island of Cos, under the shade of which Hippocrates is said, by tradition, to have held medical consultations. The tree now stands in the market place of Cos on the east side of the island. The branches, which spread over nearly the whole of the market place, are supported by marble pillars.

The *Gardeners' Chronicle* (March 22, p. 373) publishes a letter from M. Alphonse de Candolle on a botanical point of some little interest. The names of varieties of plants are usually written in the same genderas the generic name, thus:—*Thymus Serpyllum*, *β. montanus*, Benth., while sometimes the varieties are put in the feminine gender. Mons. de Candolle considers that if the word var. be used, representing the feminine Latin word *varietas*, the name of the variety will be more correctly written with the feminine termination. He recommends the use of a feminine termination for the varietal name in all cases, whether the var. or *varietas* be expressed or understood.

One of the seeds (*Spergula arvensis*) which is found largely mixed in foreign linseed, especially in Russian varieties, appears to be likely to have some value in agriculture. Lord Walsingham has recently cultivated on twenty acres of blowing sands, useless for other crops, a quantity of the plant, which yielded an ensilage, preferred by cattle to that made from grass. The plant is also said to be valuable food for poultry. Since the seed may be obtained as a waste product by the sifting of linseed, it may be hoped that the demand likely to arise for it through this observation may lead indirectly to greater purity in commercial linseed.

Dr. Dymock, in the recently concluded 'Vegetable Materia Medica of Western India,' points out the curious fact that camphor is resublimed in India, not so much with a view to its purification as to increase its weight by getting as much interstitial water as possible into the cake. In order not to lose the profit thus obtained, the camphor is sold as soon as possible after sublimation at the same price as the crude article, the profit being thus drawn out of the water.

A case of poisoning by hemlock is reported in the *British Medical Journal* (March 22, p. 576), which occurred during the previous week to some boys belonging to the training ship *Cumberland*, stationed on the Clyde. Ten of the boys became seriously ill, the chief symptom being great stupor and loss of power in the limbs. It is to be regretted that the botanical name of the plant was not reported, all that is said being that "an examination of the herb showed that it belonged to the *Umbelliferæ*, and was one of the hemlock species." The plant most likely to have ccurred on wet streamlets near the shore is *Œnanthe crocata*, and it is also the plant whose tuberous roots are most likely to have been eaten. In the interests of toxicology it is important that this plant, the hemlock water dropwort, should be carefully distinguished from the true hemlock (*Conium maculatum*), and the water hemlock (*Cicuta virosa*).

An observation that is claimed to have a bearing on the flora of the carboniferous period and the formation of petroleum is put on record by Dr. A. B. Griffiths (*Chem. News*, Feb. 29), who states that he has ascertained that phenol exists in various proportions in the free state in the leaves, stem and cones of *Pinus sylvestris*. Dr. Griffiths suggests that as phenol is also a product of the distillation of coal, this observation confirms the views of those geologists who date the existence of the Coniferæ as far back as the carboniferous period, and that further it also supports the theory that the origin of petroleum in nature was the action of moderate heat on coal or similar matter of a vegetable origin, since it is known that petroleum contains phenol and its homologues.

In a letter addressed to Sir William Thomson and sent by him to *Nature* (March 20, p. 494), attention is directed by the writer of the letter, Mr. L. P. Muirhead, to the quantity of meteoric dust that fell in Scotland on March 1, which he has calculated as amounting, over the area of 810 square miles, on which it was observed, to 5760 tons, or at the rate of 4 grains to the square foot. Curiously enough on the two succeeding days the goats suffered from influenza, and Mr. Muirhead himself had a sharp attack followed by a severe headache for a day. The coincidence, if nothing more, is a suggestive hint as to the cause of the epidemics of influenza that are occasionally recorded.

NOTES ON TINCTURE OF HYOSCYAMUS.*

BY WILLIAM GILMOUR.

Some time ago I had a sample of tincture of hyoscyamus given me to examine, which had a peculiar odour not at all characteristic of this tincture, and which also gave on the addition of water a milkiness much more decided than anything I had ever previously observed with hyoscyamus. It is sometimes not easy to distinguish a familiar odour if cunningly masked, but here there was little difficulty, particularly on diluting the tincture with water, in discovering the all-pervading odour of balsam of copaivi, and the supposition was that the hyoscyamus leaves from which the tincture had been prepared were annual leaves and had been sophisticated with the balsam so as to give the heavy odour and the milky opacity on the addition of water, characteristic of a tincture prepared from the biennial leaves. The idea was an ingenious one, particularly if we bear in mind that the annual hyoscyamus can at present be bought for as many pence as the biennial costs shillings. Unfortunately for the idea, the contamination was ultimately discovered to be accidental, but to this accident you are indebted for the following short notes.

There have been only two methods proposed, so far as I am aware, to distinguish a tincture prepared from the annual henbane leaves from one prepared as officially directed from the biennial, namely, that of the spectroscope, by the late Mr. Stoddart, and that of a milky opacity on the addition of water, by Mr. Donovan.

In the *Medical Press and Circular*, of 1871, Mr. Donovan directs "a little of the tincture to be added to a glass of water, when if the mixture becomes slightly milky the tincture (he states) is made from a two years old plant, but if it remain transparent the plant has been in its first year." Regarding the first mentioned test, Mr. Stoddart (in vol. xi., [2], *Pharmaceutical Journal*, 1869-70,) after describing the spectrum of the biennial tincture, which gives four very dark bands, goes on to remark of the tincture prepared from the annual plant, "This spectrum is very different to the last and cannot be mistaken for it. The chlorophyll line at B. is not so decided, the second and third lines so weak as to be barely visible and the fourth absent." A year later, writing in the same journal on Bristol Pharmacology, he puts the statement even more strongly, thus, "Authors have been undecided as to whether the biennial and annual plants should be regarded as distinct varieties, or the latter only a more mature growth of the former. The latter is probably the true state of the case. . . . . The microspectroscope will immediately decide whether the tincture has been made from the biennial plant. Five dark bands are distinctly seen which are not visible in that from the annual." Both tests, I may state, have been repeatedly quoted since as authoritative. Thus, so recently as vol. viii. of the present series, we have the writer of the Month article, in the *Pharmaceutical Journal*, making reference to both and saying that "practical pharmacists should not forget that the tincture of this plant (annual) does not show a milkiness when mixed with water, as that made from the biennial does, nor that the preparation made from the two kinds can be distinguished, as shown by Stoddart, by means of the spectroscope." Now it is not easy for investigators to arrive at any definite conclusion as to what is meant *commercially* by annual henbane. I find that the term applies indiscriminately to leaves derived from a variety of sources. Thus we have the British annual henbane proper; and the root leaves of the biennial plant, which Mr. Holmes informs me usually forms the annual of English commerce; then there is what is known as German henbane, and probably a whole variety known somewhat vaguely as exotic henbane. Through the kindness and courtesy of Mr. Holmes, of the Museum department of the Society in London, I received samples of different kinds of henbane (samples of these as well as tinctures prepared from them are on the table and may be examined by members), and among others, one sample of the real German annual. I am persuaded, after comparing somewhat minutely this sample with those of the commercial received by favour from various wholesale houses, that very much of the annual henbane at present in circulation is of German origin. Be this as it may what we, as practical pharmacists, have to do is to accept and judge matters as we actually find them, and, therefore, I have to point out that of all the annual specimens which I have examined, I have not found one which did not give a spectrum as well defined as that derived from any specimen of the biennial plant. Indeed, I have found the bands of the spectrum more uniform and more decided from the various specimens of the annual plant which I have examined, than I have found from an equal number of specimens of the biennial plant. We must, therefore, once for all give up the spectroscope as an agent for distinguishing the one from the other.

It is probably not in the power of every one to apply a spectroscope to his tincture, but I will here shortly describe how a rough but very fair tes

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, March 19, 1884.

may be applied to this tincture, showing its age, quality, etc., without going to the expense of a spectroscope.

To two parts of tincture in a test tube, add one part ordinary commercial benzole; shake thoroughly and allow to stand for a short time. The benzole will be found to separate, taking with it almost every particle of green colouring matter, leaving after a time a clear tincture beneath. So thoroughly does the benzole extract the chlorophyll that it leaves scarcely the trace of a dark band in the tincture beneath, and from the depth of the green solution above as well as from the colour of the brown tincture below as good an indication will be given of the value of the tincture as can be got almost from the spectroscope itself. I have here a whole series of test tubes filled with tinctures thus treated, and, as can be seen at once, the shades of colour vary considerably, both in the chlorophyll solution above and in the tincture beneath. The history of these different tinctures will be referred to immediately, but I would in the meantime call attention to test tube numbered 3, which contains the tincture of German annual received from Mr. Holmes and which you will find not the least marked both as regards the chlorophyll solution above and the brown tincture beneath. So much for the spectroscope as discriminating between a tincture prepared from the annual and biennial plants.

Coming now to the other test, namely, that of the milky opacity on the addition of water, I have not found one single sample of biennial which failed to give it, nor can I recollect of ever coming across such a sample during the last eight or ten years in the ordinary course of business. I would, therefore, unhesitatingly reject as bad, owing to age, or from some defect in drying or from exposure, or other cause, any biennial plant the tincture from which failed to yield it. In saying this, however, I am saying all that can be said for this test. It is *not* a test which can distinguish the biennial tincture from the annual, for I have come across as many specimens of the latter which do give the milkiness as of those which fail to give it. Of those which give the milkiness, some give it at once, while others only give it after standing for some time. This last fact may be the reason why the reaction has not been more frequently observed. The tincture from the German annual, which we have here, for example, gives it readily and copiously, and, in every respect as well, answers all the tests of a good biennial spemen, with the exception of the odour. Probably most will have noticed the heavy fetid odour (not unlike ox-gall) which the biennial tincture gives on the addition of caustic potash. This peculiar odour is almost entirely wanting in every specimen of tincture prepared from the annual plant which I have examined, the odour being quite different. In this respect the sample of the annual on the table closely resembles the tincture prepared from the large stem leaves of the biennial sample received from Mr. Holmes. This sample makes a very inferior tincture and is not for a moment to be compared to the tincture prepared from the leafy tops received also from Mr. Holmes.

It was originally my intention to have confined my notes to the two points touched upon, but after proceeding with the examination of the different specimens placed at my disposal, my attention was directed to a paper read by Mr. Gerrard, at the last meeting of the Pharmaceutical Conference, on "The Odorous Principle of Henbane Leaf." In a concluding note to this paper, in which Mr. Gerrard practically applies his investigations to pharmacy, he points out not only what I have just shown as regards the turbidity test, but goes on also to deduce several conclusions from it which, according to my experience, will, I think, scarcely stand the test of experiment. He states for example that "many samples of tincture of henbane almost lose their property of becoming turbid with water; this is generally the result of age, for such a tincture will be found to have lost its original green colour and changed to a brown with formation of the usual dark deposit. Thus deposition and disappearance of turbidity are simultaneous and proportionate. As to the nature of the deposit in the tincture, I believe if examined it will be found to consist of a mixture of odorous principle, fat and chlorophyll, the separation of which is slowly effected by the agency of the water in the proof spirit; if this be so, then it is an argument for the use of a stronger alcohol in the making of the tincture of henbane."

I called Mr. Gerrard's attention to the fact that I had exposed a tincture of henbane to ordinary light (no sunshine), and in three weeks it had lost almost every trace of green colouring principle, while it had not deposited in the least, nor had it lost its property of becoming turbid with water. To this Mr. Gerrard replied that the tincture had not been kept sufficiently long, but that with the changing of the chlorophyll the tincture would have become acid (it shows no signs of acidity up to the present time), this acidity increasing with age, and that the deposit referred to by him would take from three to six months to form. I believe Mr. Gerrard is quite right in his observations, although I think he is wrong in his deduction that this change is "slowly effected by the agency of the water in the proof spirit." Some years ago I pointed out that these very changes here described by Mr. Gerrard took place in olive oil on exposing it to light. There was first the gradual decomposition of the chlorophyll and the disappearance of the bands in the spectroscope; next, an increasing cloudiness in the oil, accompanied by an increasing acidity, all of which, I have no doubt, would have ended in a deposit as described by Mr. Gerrard had the density of the oil permitted this, or had it been kept long enough. The water could scarcely in this instance be said to be the agent which either favoured decomposition or tended to effect separation. But further and more important still, I have to point out the much greater susceptibility of a tincture of henbane to change when prepared with a stronger as compared with a weaker alcohol. I have prepared duplicate tinctures with rectified spirit of every sample of henbane on the table, and two things cannot fail at once to strike even an ordinary observer regarding them, namely, first, the close resemblance which they all (annual and biennial) bear to each other, and, second, the striking unlikeness which they have to a tincture prepared from proof spirit. They have all the same deep green coloration, not unlike essence of bergamot, or better still, like commercial cajeput oil, and this characteristic feature, so striking in the first instance, is equally remarkable for its evanescence on exposure. I find that even twelve hours exposure will quite change their appearance, and this change goes on so rapidly that towards the end of a week the tincture becomes almost decolorized. I have here two tinctures thus exposed, which you can compare with samples of the same tincture carefully preserved. Twelve hours' exposure removed every trace of bright green, converting the tincture into a brown olive, and this in turn gradually faded, until it reached on the seventh day the dirty straw-white which you now see. This you will admit is of itself a very serious objection to any change in the spirit strength of the tincture, more especially if we keep in mind, comparatively speaking, the permanent character (to the naked eye) of the official tincture, three weeks exposure under similar conditions making scarcely any observable difference in it.

There is still one more objection to changing the spirit strength of this tincture, and to my mind it is the most serious of all, namely, that the stronger spirit does not exhaust the leaves of their active principle. In saying this I know that I am going not only in the face of Mr. Gerrard, but also of such an eminent authority as Christison, who says that the leaves impart their active principle alike to alcohol and proof spirit. From the very great change which has taken place in the rectified spirit tincture on exposure, as well as from the entire absence of any colouring principle except the chlorophyll when treated with benzole as already described (on agitating the rectified spirit tincture with water and benzole, the benzole extracts every particle of green colouring matter and leaves the tincture beneath absolutely colourless), I think there is every reason to conclude that the stronger alcohol exhausts the leaves to a very great extent of their green colouring matter and not to any extent of their active principle. In further proof of this I have to point out that with wonderful uniformity all the proof spirit tinctures contain from five to six times the amount of extractive matter compared with the stronger spirit tinctures prepared from the same samples. The table underneath sufficiently explains itself.

No. 1. German annnal, proof spt. = 1·05 per cent. extractive.

No. 2. German annual, rect. spt. = ·20 per cent. extractive.

No. 3. Large leaf biennial *ver.*, proof spt. = 1·40 per cent. extractive

No. 4. Large leaf biennial *ver.*, rect. spt. = ·20 per cent. extractive.

No. 5. Biennial tops *ver.*, proof spt. = 1·40 per cent. extractive.

No. 6. Biennial tops *ver.*, rect. spt. = ·20 per cent. extractive.

No. 7. Biennial commercial (1), proof spt. = 1·20 per cent. extractive.

No. 8. Biennial commercial, rect. spt. = ·21 per cent. extractive.

No. 9. Biennial commercial (2), proof spt. = 1·20 per cent. extractive.

No. 10. Biennial commercial, rect. spt. = ·5 per cent. extractive.

Of course extractive matter is not active principle, and the correct plan to determine the relative value of the two tinctures would be to estimate the amount of hyoscyamine present in them. I have been experimenting on quantities much too small to permit of this, and, moreover, it was not my intention, as I have already explained, to enter into the question of a stronger or a weaker tincture, so that I have not had time to do so, even although I had so desired.

To sum up my observations, we have—

First. The fact that the spectroscope does *not* distinguish between a tincture made from an annual or a biennial plant.

Second. That the milky turbidity on the addition of water is not a test to distinguish the one from the other; but it is a fairly good test as to the quality, so far as age, exposure, etc., of the biennial plant is concerned.

Third. That a proof spirit tincture, although quickly changing so far as the chlorophyll matter is concerned, does not show this change to any extent to the naked eye, while the more important chemical changes which ultimately affect the quality of the tincture therapeutically are comparatively slow.

Fourth. That a rectified spirit tincture undergoes very rapid changes, which are very conspicuous to the naked eye, and which are almost certain to end in rapid chemical changes affecting the therapeutic value (if it possesses any) of the tincture.

Fifth. That rectified spirit does not possess the same power of exhausting the henbane of its extractive matter as proof spirit.

Sixth. That a rectified spirit tincture and a proof spirit tincture are quite unlike in their appearance, so much so as practically to make them unrecognizable.

[*The discussion on this paper is printed on p.* 790.]

NOTES ON PHARMACEUTICAL APPARATUS.*

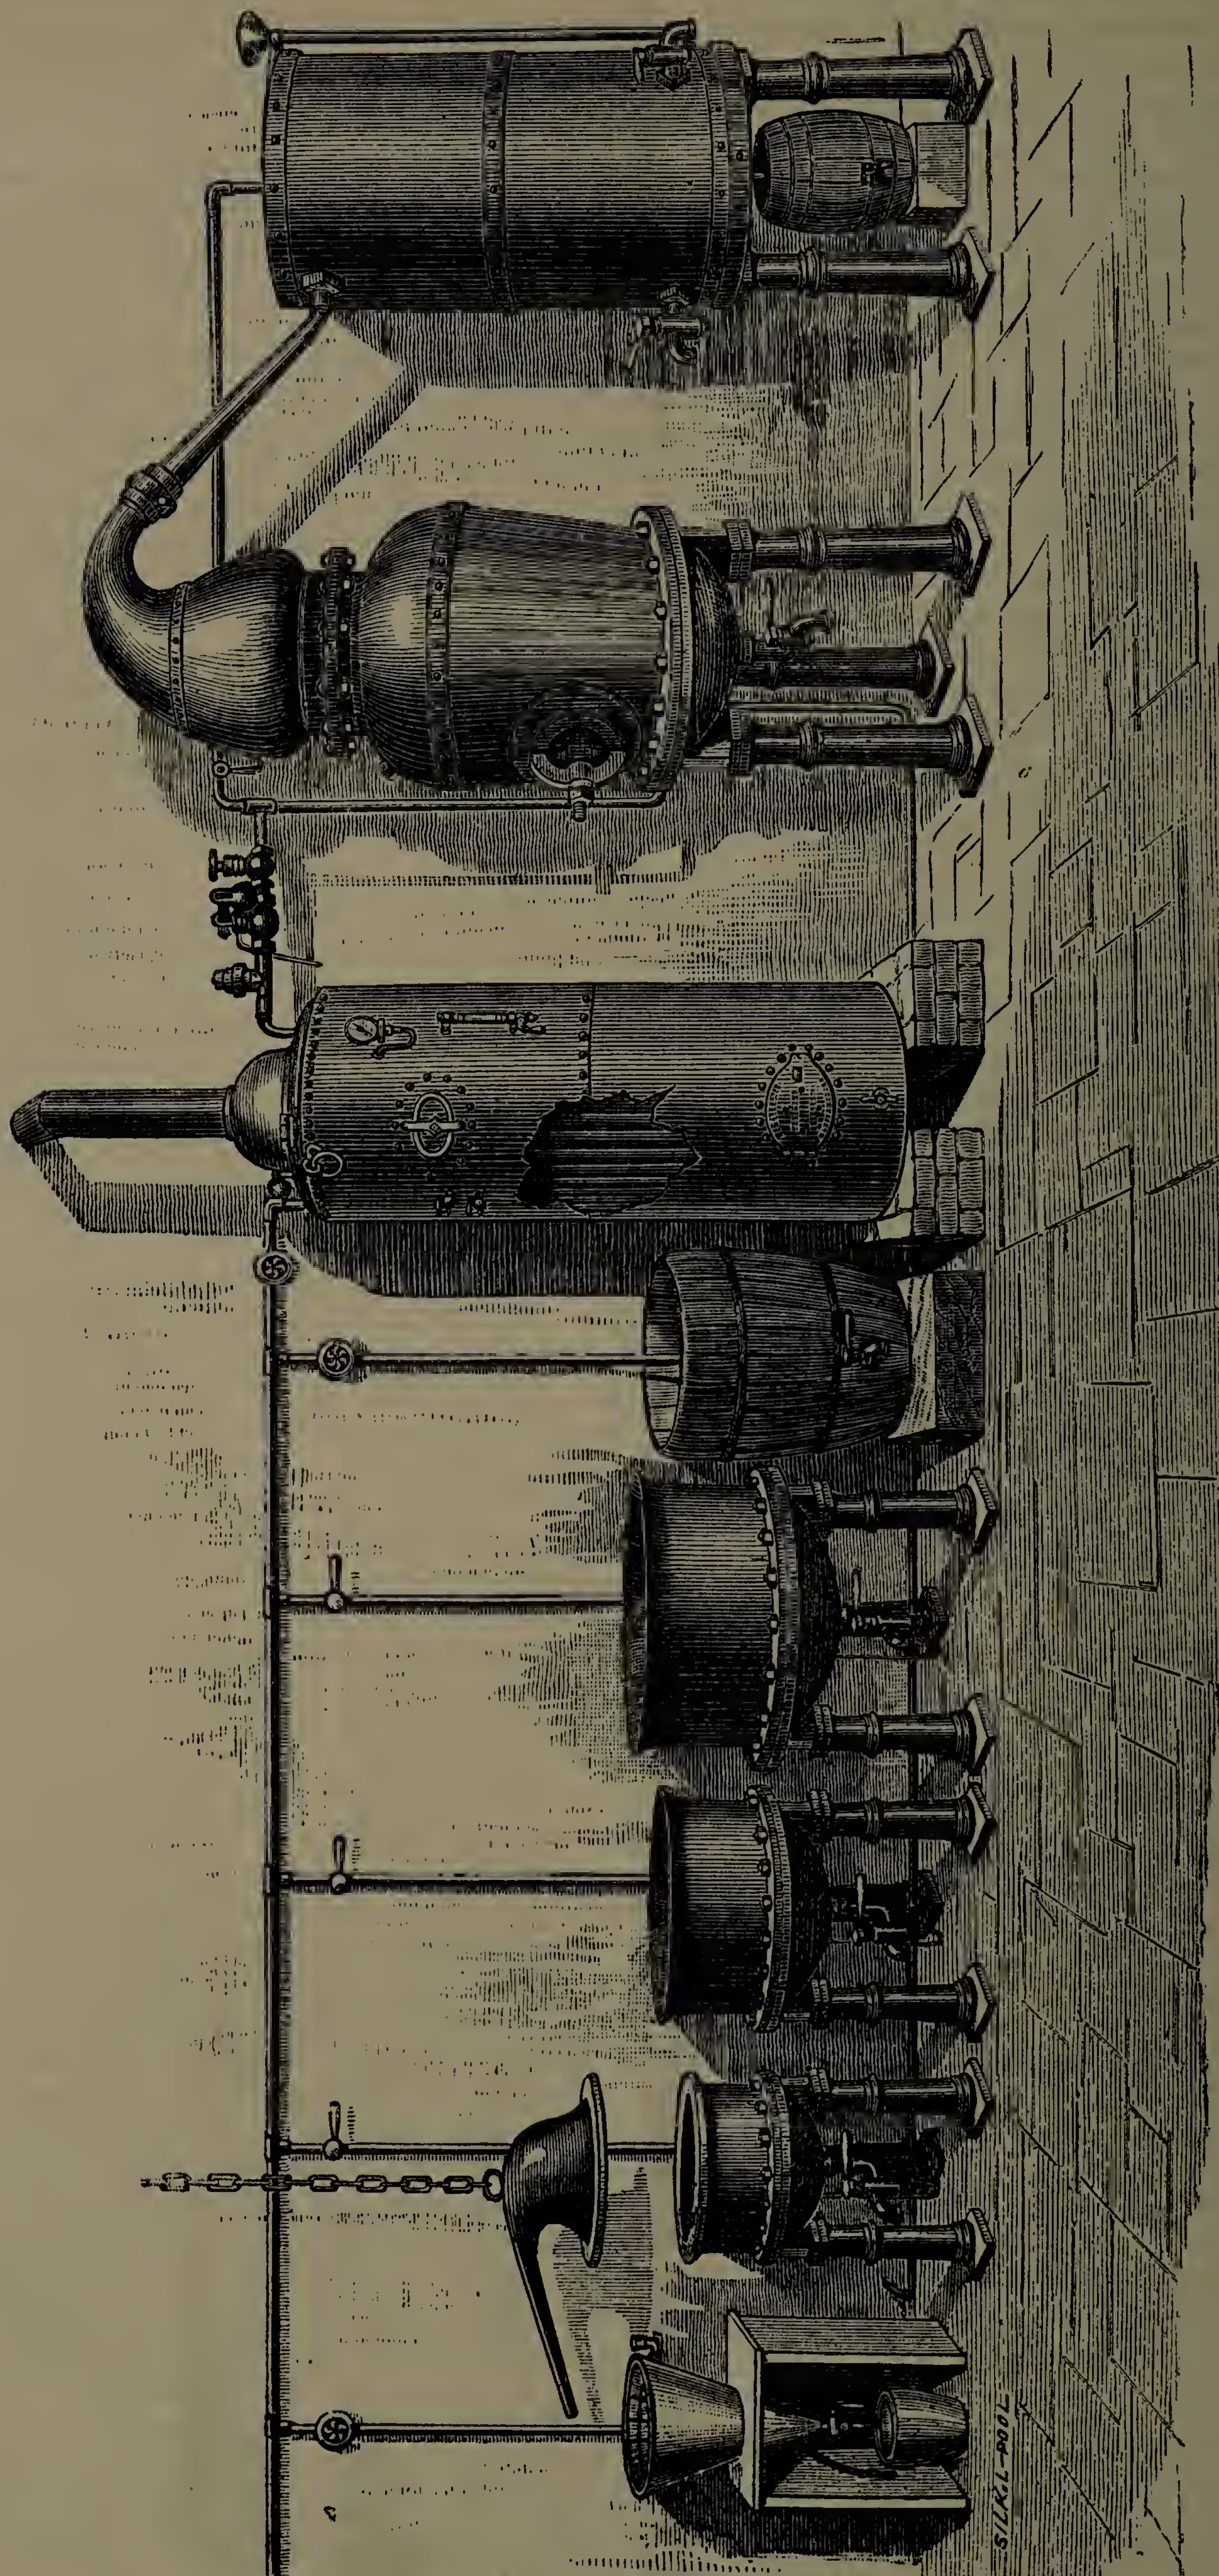
BY CHARLES SYMES, PH.D.

Some years ago, Mr. Ince (I believe it was Mr. Ince) wrote thus, or to this effect, "I have a good deal of faith in a man and a pan, provided the one has brains and the other has capacity." These words forcibly conveyed to my mind, that, in the opinion of the writer, a man of good average intelligence, with simple apparatus, sufficiently large for his purposes, could accomplish much in the way of manufacturing pharmaceutical preparations; and I think there can be little doubt that a pharmaceutical sermon, having "a man and a pan" for a text could, in able hands, be rendered both interesting and instructive.

As a busy man, having my time pretty fully occupied with the duties of my calling I merely propose to bring before you this evening some ideas concerning, and description of, a few simple but useful forms of pharmaceutical apparatus. I do so under the following circumstances.

Last year a friend from South America, when visiting Liverpool, desired to see our laboratory, about which he had probably formed some exalted notions; but on being shown the very modest equipment, after some conversation he said, "If so much practical work can be accomplished by such simple means, send me some similar things, such as your experience suggests as being necessary and useful to commence with for a small laboratory, and to which I can add as occasion requires." The work (except percolators, retorts, and minor matters) was, with rough drawings, placed in the hands of Messrs. Thomas Ryder and Co., engineers, of Manchester, and was by them executed in a highly satisfactory manner. I may add that as the apparatus

* Read at a meeting of the Liverpool Chemists' Association, February 28.



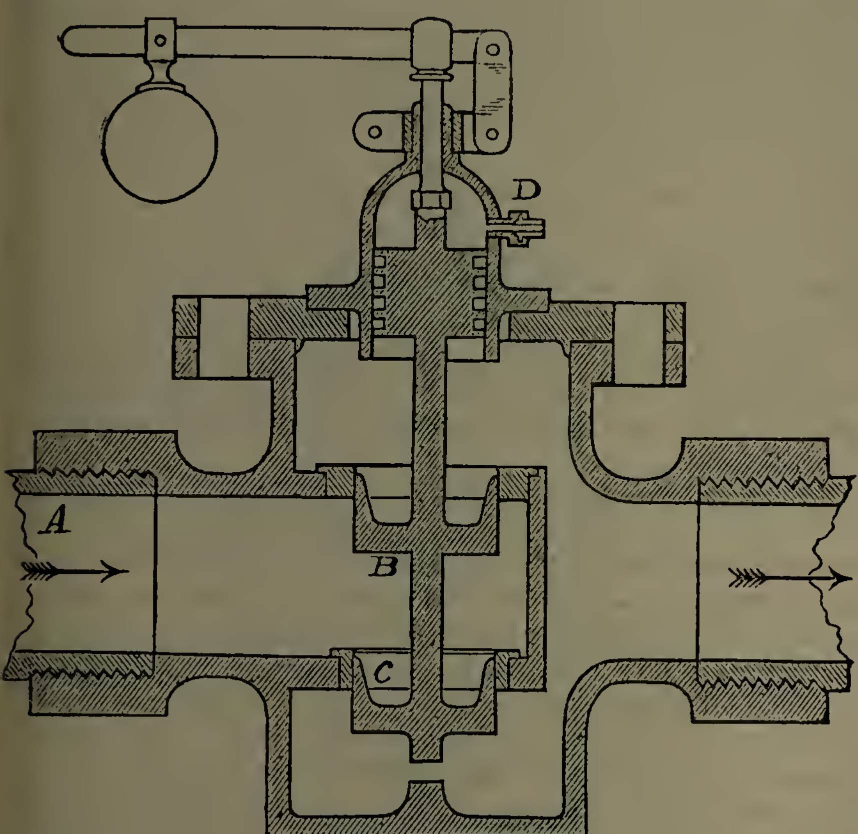
Pharmaceutical Apparatus.

As constructed by Messrs. T. Ryder and Co., Manchester, for Messrs. Symes and Co., Liverpool.

The boiler has been introduced to show the working position.

had been shipped long before it occurred to me to write this communication, I am indebted to them for a photograph and some particulars to refresh my memory and enable me to bring the matter before you in what I trust will be a clear and explicit manner.

I must mention that our friend had already a high pressure boiler working an engine and other machinery, and we had, therefore, to start with a reducing valve.



This valve is made of gun metal and is so arranged on the steam supply main that it reduces the pressure therein from the actual pressure of the boiler, say 60 lbs., to 2 or more pounds per square inch, as may be desired.

The steam entering at A, and acting equally on the two valve faces B and C, it will be seen that there would be no passage but for the lever, which is weighted in such a manner as to allow just sufficient steam to pass through to produce the lower pressure and temperature. To the small union connection, marked D, is attached a brass tube to convey away any moisture from the upper chamber which may accumulate by the condensation of steam as it is passing through the valve; and it also serves to prevent the possibilty of a vacuum being formed which would hold the valves in check and prevent them from working freely.

As most pharmacists would provide a boiler specially for working such apparatus I am about to describe, let me say a few words about boilers, the choice of one being a matter of some importance. Our own is a small upright tubular, 4½ feet high by 26 inches diameter; it stands on nine inches of brick-work, and occupies but little space in the laboratory. An iron pipe, covered with felt to lessen condensation, runs from it round two walls of the building to supply steam to stills, pans, funnels, etc.

To have a boiler too small for the purposes required is a decided mistake; it is better to err in the opposite direction, as anyone with experience in these matters will know how trying it is to run short of steam when two or three preparations are in hand and a lot of evaporation has to be done. There is of course a limit in size, beyond which it is not desirable to go, first on account of space, and secondly on the score of economy in time and fuel, for if a much larger boiler is used than is really required there is so much more water to be heated each morning at the expense of these two items.

Boilers are usually described as of one or more "horse power," and to obtain this unit in the most simple form the following conditions are necessary, viz., 1 square foot of fire grate and 1 square yard of heating surface; these, with an expenditure of 14 lbs. of coal evaporate 1 cubic foot, or rather more that six gallons of water per hour, which, in the form of steam applied to a Boulton-Watt engine would perform the work of one horse for that period of time. A two horse boiler is sufficiently large where machinery is not used, and an upright tubular one is the best for "getting up steam" quickly. In this, coke should be used in preference to coal, as the latter is liable to choke the tubes with soot very readily. Although it should be tested to bear a pressure of at least 100 lbs. to the square inch, not one tenth this amount is generally used for pharmaceutical purposes.

With a low pressure boiler, then, a reducing valve is not required, and the steam is taken direct from it to the point at which it has to be used, merely interposing a screw stop valve on the main, which in such position is better than an ordinary tap, as it affords a more convenient means of regulating the supply. In the arrangement shown, a tub, three pans and a funnel are placed on one side of the boiler; a still and condenser on the other side. Into the tub passes a block tin pipe, terminating on the bottom in a flat perforated coil; a short distance above which, rests a perforated false bottom, such an arrangement being convenient for steaming and boiling purposes, where the ingredients are bulky, as in the case of decoctum sarzæ comp., etc.

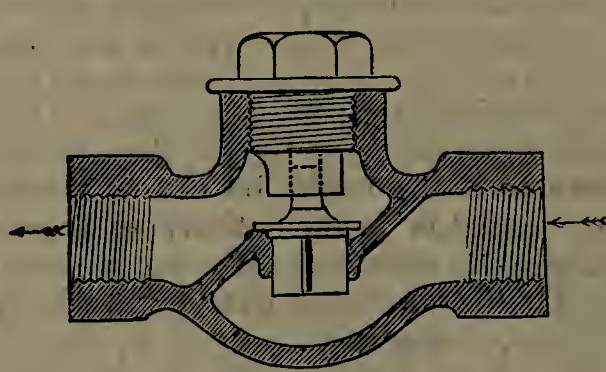
The pans are of copper, jacketted with cast iron, leaving a steam cavity over the lower part only. This provides sufficient heating surface for rapid evaporation, and avoids to some extent the inconvenience and possible deterioration of the product caused by the drying which always occurs on the outer edge of the liquid where it comes in contact with the sides of the pan when it is jacketted to the top. Constant stirring will of course obviate this to some extent, but even with this, and the old arrangement, it is not easy to remove the difficulty.

The capacities are 40, 20 and 10 gallons, and the internal measurement, 30 × 24, 24 × 20 and 18 × 17 in. respectively, and such a one is fitted with a check valve, or tap, vacuum valve, and a syphon pipe and back pressure valve at the outlet for waste steam; it is self-contained, requiring only the attachment of the steam supply and waste pipes, so that if thought desirable, the relative positions could be changed with ease. The steam funnel is made entirely of copper, well tinned inside, and the steam chamber is continued to the top. The steam supply enters at a ⅜-inch union near the top, makes the circuit of the chamber and passes out at right angles to the side of the funnel, more or less condensed, near the bottom. The exit tap is somewhat large in proportion to the funnel itself, the object of so having it being to prevent any possibility of choking up and to provide a good exit for any thick or partly solid filtrate. The interior of the funnel is fitted with a tinned wire cagework which can be removed at will, its obvious use being to prevent the filtering material from touching the sides of the funnel and for preserving a clear passage for the filtrate in all directions, whilst the support given is practically equal to that by a solid surface. Near the top is placed a small safety valve which is regulated to blow off at 5 lbs. pressure. The main steam pipe (if not required for drying closet) should terminate in this direction with a T-piece, fitted with screw tap and hose connection, so that a rubber tube can be attached when desired; it is useful for many purposes, one example is that of steaming nux vomica beans before grinding.

The still is placed on the opposite side of the boiler; it is of copper with a cast iron jacket, similar to those on the pans, and has fittings like them. In the body of the still is a gun-metal hand-hole for removing any solid residue and for cleaning out purposes. It is also fitted with a removable perforated false bottom for separating any solid matter from the liquid contents drawn off by the tap underneath. The distillate is condensed in a block tin worm contained in a circular wrought iron cistern of 60 gallons capacity, the exit being from the side near the bottom.

Passing direct from the boiler is a steam-pipe which terminates in another block tin worm at the top of the cistern, going within the coil of the other worm and out at the centre of the bottom of the cistern. Underneath is a stoneware barrel to receive the distilled water as it flows from the last-named worm. This is found to be a convenient arrangement, and whenever the pressure is increasing unduly round the still or pans, or when it is necessary to stop the working of one or more of these, then the distilled water tap can be turned on, with the result that one has a good supply of distilled water, practically free of cost.

It has been mentioned that each pan is fitted with a syphon pipe and back pressure valve. The former prevents waste of steam, and consequent power; a foot of condensed water in the pipe would represent approximately half a pound of steam pressure. The latter prevents the waste steam from one pan from entering the chamber of the next, replacing a tap and acting automatically; it is exceedingly simple, as will be seen from the drawing. The arrows indicate the direction in which the steam (or condensed water) passes, lifting the small valve in the centre and moving forward freely; but if it attempts to pass in the opposite direction, the more tightly the valve is closed against it.



The apparatus described does not by any means constitute the equipment of a pharmaceutical laboratory, but it forms some of the essentials for every-day work, and a foundation on which to build. The capabilities are but moderate, still the expense is moderate also. The cost, exclusive of main supply and waste steam pipes, the tub and stone barrel, is £110. A two horse upright tubular boiler costs £28 or £30, so that the whole could be fitted up for something like £150. The still, pans and funnel are tested by hydraulic pressure to bear 20 lbs. on each square inch of surface.

Doubtless, different pharmacists work their apparatus at different degrees of pressure. My experience is that with pans of the size mentioned a pressure of from 2 lbs. to 5 lbs. to the square inch, giving a temperature of from 216° to 225½° F., is the most suitable when stirring is actively continued, and when not stirring, a nominal pressure, say of ½ lb. to the square inch is quite ample.

[*The discussion on this paper is printed at p.* 790.]

NETTLE-FIBRE.

In the *Deutsche Allgemeine Polytechnische Zeitung*, Dr. J. Moeller gives a report of experiments on the histological characters of the fibre of the common stinging-nettle, *Urtica dioica*, and its applicability to technological purposes.

The primary bast-bundles of the stem do not form a connected ring, and its fibres are mostly separated by intermediate parenchyma. The cortical parenchyma is not sclerenchymatous. At the base of the stem the fibres are mostly about 0·12 mm. in diameter; higher up they are thinner; but even at the summit they have a diameter of 0·04 mm. The thinnest fibres of the nettle are therefore as thick as the thickest of hemp. In consequence of their isolation they are seldom polygonal. At the commencement of the time of flowering the fibres in the upper portion of the stem only are completely thickened; those in the lower part have still large cavities. There are no pore-canals. Fibres were measured 22 mm. in length; they are very irregular in form. They consist of nearly pure cellulose; their behaviour with cuoxam is characteristic. They swell with extraordinary rapidity from without inwards; a sharply differentiated internal layer resists the action for some minutes; but this is also at length dissolved; and in addition to a small quantity of contents of the fibres a delicate network remains, the primary membranes of the parenchyma cells which surrounded the fibres.

Fibres baked or treated with acids or alcohol show two peculiarities. They are very irregularly isolated, being either united into bands or disintegrated into separate fibres; there are no thin bundles, like those of combed flax or hemp. This peculiarity depends on the structure of the primary and on the want of secondary bast-fibre-bundles. The second peculiarity is their complete and nearly regular investment with parenchyma, in consequence of which they are rough and dull; resulting from the incomplete differentiation of the wall of the fibres and of that of the parenchyma-cells.

Both these peculiarities are very disadvantageous to the employment of the nettle-fibre as a technical product. The chemical means employed to separate the fibres completely from the surrounding parenchyma would affect injuriously the fineness of the fibre.

Attempts have been made to naturalize in Germany the North American *Laportea pustulata*; but similar disadvantages attend the structure of the fibre. In August the bast-fibres in the upper third of the stem are not yet developed; in the lower portion they are but imperfectly thickened. The cortex, bast and fibres, resemble those of *Urtica dioica*; but the fibres are considerably larger at the base of the stem, usually 0·5 mm. in diameter, and more than 80 mm. long; in the middle part of the stem they have still a diameter of 0·1 mm. They consist of pure cellulose; they dissolve rapidly and completely in cuoxam, leaving behind a parenchymatous network and the protoplasmic contents of the fibres.

The Pharmaceutical Journal.

SATURDAY, MARCH 29, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PROPOSED LEGISLATION AS TO POISONS.

THE past week has not been without its history, for on Wednesday, Mr. WARTON's exceptional effort at constructional legislation,—the Bill to Restrict the Sale of Patent Medicines—was withdrawn, after a brief public existence of only seven days. This result was not unexpected in view of the declaration of the Government as to its intention to deal with the poison question, and little ingenuity was required to anticipate the tenour of the greater part of the discussion attending the withdrawal in the House of Commons, which will be found on another page. The member for Bridport is evidently strongly impressed with the evils consequent upon the unrestricted sale of poisons under the guise of patent medicines, and the measure proposed by him for diminishing them can hardly be said to have been wanting—in intention, at least—in stringency. Whether the provisions would have proved workable is quite another affair, and notwithstanding the high compliment to the Pharmaceutical Society implied in the willingness of the honourable member to entrust it with the onerous—and honorary—duty of carrying them into effect, it is not probable that the collapse of the proposed arrangement will arouse much regret in that quarter. Nevertheless, Mr. WARTON did good service in impressing upon the attention of the Legislature the fact that the very same poisons that it has decided shall not be sold in an undisguised form except by skilled persons and under certain restrictions, are being sold under the cover of the patent medicine stamp by any persons and without any precautions. Moreover, he very properly pointed out that the makers of innocuous preparations would have no difficulty in placing them outside the operation of the proposed law. In connection with this latter point it is rather curious—though under the circumstances perhaps hardly worth noticing—that such a high authority as the Attorney-General appeared to be imperfectly acquainted with the actual provisions of the Bill that he was discussing. In order to enforce his argument, he said that according to the Bill, if, on analysis, one trace of poison, however slight, should be found in a preparation, notwithstanding the medicine might be of a beneficial character, it must be labelled poison and the sale of it must be regulated by all the forms prescribed by the Pharmacy Act. Now apart from the fact that this appears to be a reversal of the order of the Bill, according to which a patent medicine was to be considered a poison until it had been declared non-poisonous, a reference to the second clause will show that the provision as to the Pharmaceutical Society passing a resolution to the effect that a patent medicine contained poison would have been permissive in its terms, and that even in the event of such a resolution being passed it would have required the sanction of the Privy Council before coming into force, a not unimportant limitation.

Dr. FARQUHARSON, who, from the fact that his name was on the back of the Bill, might have been expected to bless it rather than to ban it, did not betray any excessive admiration for some of its provisions. His view that an authoritative declaration, based on analysis, such as was proposed, would increase the tendency of the public, already imparted by the revenue stamp, to look upon such medicines as bearing a Government sanction, is no doubt correct. Indeed his suggestion that the Government should sacrifice the sum derived from the patent medicine stamp duty will probably commend itself to most persons who have considered the subject apart from the necessities of the public revenue. It is satisfactory to observe, however, that although it was outside the scope of the Bill under discussion, Dr. FARQUHARSON's appeal to the Government to consider the anomalous liberty at present allowed to co-operative stores in respect to dealing in poisons was endorsed by the approval of his hearers.

The arguments for the rejection of the Bill were of two kinds. That by Mr. W. JAMES was advanced from the point of view from which the Bill would naturally be regarded by persons interested in the patent medicine traffic. No doubt regulations dealing with the question in any way will constitute an interference with trade and will exercise a limiting influence in direct proportion as the nostrums to which they apply contain those substances that are supposed to exercise a deleterious influence upon the public health. But the emphasizing of the enormous proportions of the traffic and the extent to which it would be affected by restrictions imposed in the interest of the public will hardly be accepted as a reason that nothing should be done to control it. Moreover, in the face of well-known official statistics that had already been referred to in the course of the discussion, it seemed barely courteous to the House to assert that during the last two years not more than seven deaths had occurred through poisoning by patent medicines. No serious discussion could be maintained on the basis of such a statement. The reason urged by the Attorney-General for the rejection of the Bill, that the Government is prepared to deal with the question in a broader sense, was much more reasonable, and probably Mr. WARTON will consider that his object has been sufficiently attained in eliciting a definite statement as to the introduction of a Government Bill. In conclusion, we may remark that in referring to this subject recently, we ventured to express an opinion as to its unsuitability for treatment by "amateur legislators," and, although members of parliament were hardly the class to whom it was intended to allude, this latest episode in the poison controversy seems to show that even that further application of our remark would not be unwarranted.

THE PROGRESS OF METEOROLOGY.

The annual Report of the Meteorological Council to the Royal Society, which makes its appearance about this period of the year, is usually more suggestive of an enormous amount of investigation that remains yet to be undertaken than of any very marked progress in acquired knowledge of the science. This is attributable, however, rather to the *laches* of the past than to want of energy amongst present investigators, though the infinite extent and variety of the field wherein the work has to be done is apt to bewilder the uninitiated as to the object towards which all this effort is tending. In fact, observations continuous and ubiquitous are at present of prime importance, in order to provide the material from which future generalizations shall educe the laws, if there are any sufficiently apparent, that affect the rule of sunshine or of storm. The ambition of the meteorologist is far-reaching, and in this fact there is justification for the hope that the service that will be eventually rendered to mankind by his science will be great. Whether it ever will be possible to prognosticate trustworthily as so the character of a coming season, or to advise a farmer in the spring as to the crops that will best suit the weather conditions of the succeeding summer and autumn, is at present very problematical. But it is a step towards it that across the Atlantic, and in the Old World to a less degree, some success has been attained in forecasting the weather for more limited periods; whilst the acceptability to the public of this amount of service is shown by the fact that weather reports and prognostics are no longer confined to the *Times*, but are now to be found in most daily newspapers of any pretensions.

In fact the portion of the report just issued that will interest the widest circle of readers is probably that which deals with weather telegraphy, and the details connected with the preparation of the forecasts now become so familiar. Briefly it may be stated that the office receives, when the telegraphic communications are perfect, fifty-three reports every morning, thirteen every afternoon (except on Sundays) and nineteen each evening. The foreign reporting stations are twenty-three in number, and extend along the entire western coast of the Continent and include four stations on the Baltic coast and one in the Mediterranean. At present, forecasts are issued twice a day, at 11 a.m. and 8.30 p.m. The first, which is based on the reports of observations taken at 8 a.m., and arriving between 9 and 10, refers to the probable weather between noon on the day of issue and noon on the day following; this is supplied to the afternoon editions of the newspapers and posted up in several public places in London. The observations on which the 8.30 p.m. forecast is based are taken at 6 p.m. This forecast comes, however, first under the cognizance of the public in the newspapers of the following morning, so that it has the disadvantage of not being read generally until twelve hours after it has been drawn up and fourteen hours after the observations upon which it is based were taken. The Council has had the subject of this delay in the publication of the most widely-read of the two sets of forecasts under its consideration, and has ascertained that for the London morning newspapers and the local issues of those in the more important provincial towns the delivery of the forecast might be made as late as 2 a.m. This would, however, necessitate the organization of a night service, for the cost of which there are no funds available. But it is stated that should the public interest in securing at an earlier hou such information as to probable weather as is conveyed by forecasts become sufficiently developed to induce local authorities of various towns to contribute their quota of the cost of procuring it and to undertake its distribution in their respective neighbourhoods, the Meteorological Office would have no difficulty in supplying it.

In presence of this challenge it will be interesting to observe the value of these forecasts as indicated by the measure of success claimed for them in the Report. Taking the average of the eleven districts into which Great Britain and Ireland are divided the proportion of success attained during the year ending the 31st of March, 1883, is represented as having been equal to 79 per cent., being an improvement of one per cent. as compared with the previous year. This total is divisible into "complete success," 44 per cent., and "partial success," 35 per cent. The greatest amount of "complete success," 50 per cent., was attained in the south of England, the smallest amount, 40 per cent., in the north of Ireland. The proportion of storm warnings sent to the coasts which were justified by subsequent events amounted during the year to 82·5 per cent., showing a slight improvement. It is admitted that the year formed no exception to its predecessors in the fact that more than one serious storm occurred of which no warning was given, but it is believed that such occasional failures are unavoidable. This fact, however, does not detract from the value of service to life and property rendered by so large a proportion of justified warnings out of upwards of five hundred issued during the year. Another valuable service rendered by the Office was the issue of special forecasts gratis during the hay harvest of 1882 to persons selected by the Royal Agricultural

Society, the Royal Dublin Society and the Highland Society, in different parts of the three Kingdoms, on the condition that the information should be made as widely known as possible, and that a record should be kept of the value of each prediction and sent in weekly. From a tabulation of these reports it appears that "complete success" was attained in respect to 50 per cent. of the forecasts, and "partial success" in 37 per cent. more, whilst the total failures amounted to only 2 per cent. These forecasts were evidently highly appreciated as having an actual money value, and for one district where the hay harvest was late they were prolonged for an extra four weeks at the expense of the recipients. Although the foregoing deals only with a portion of the Report the facts are sufficient to shadow forth the services that meteorological science is capable of rendering to the community in one direction. In another, closely affecting the health of the metropolis, investigations have been continued, as opportunity offered, into the causes and prevalence of London fog. The opportunities, though too frequent to be pleasant, proved hardly sufficient to yield valuable results. But a previous observation as to the abnormal increase of the proportion of carbonic acid gas in the atmosphere has been confirmed, the quantity having risen to 13 parts per 10,000 on one occasion, or more than three times the usual amount.

The last Evening Meeting of the Pharmaceutical Society in the present session will be held on Wednesday next, when a paper on "The Aqueous Extraction of Cinchona Bark," by Professor Redwood, and one on "The Proximate Analysis of the Seeds of Amomum Melegueta," by Dr. Thresh, will be read. The chair will be taken at half-past eight o'clock, but the Curator will be in attendance an hour previously to furnish information respecting recent donations to the Museum that will be exhibited.

* * *

In the House of Lords, on Friday the 21st inst., the Chairman of Committees informed the House that the promoters of the Institute of Chemistry Bill did not intend to proceed further with it. The order of the day for the second reading was therefore read and discharged. It is understood that the promoters hope to attain the incorporation contemplated by the Bill by means of a Royal Charter.

* * *

A correspondent from the south has forwarded to us a warning against an impostor who appears to operate by calling upon a chemist and druggist, and upon the pretence that some person in the neighbourhood has promised to pay for a truss for him, obtaining an estimate of the price of a suitable instrument written upon a bill-head. Armed with this document he canvasses for subscriptions among the benevolent in the locality, and, it is needless to say, when he has exhausted this field betakes himself to another.

* * *

Previous to the election of the present President of the Chemical Society to that office, he had during fourteen years filled the office of one of its Secretaries, and had in many ways shown his interest in the Society. It is now proposed as a mark of recognition of these prolonged services to entertain Dr. and Mrs. Perkin at a dinner at Freemasons' Tavern on the 23rd of April. It is understood that Professor Hofmann has promised to come over specially from Berlin to preside at the dinner.

* * *

In giving evidence recently before a parliamentary commission appointed to inquire as to the causes of the commercial crisis under which France is suffering, M. Vée stated that the manufacture of chemicals had remained stationary in that country during a time in which it had increased five-fold in other parts of the world. One of the causes to which he attributed this stagnation was the imperfect education of French workmen, which made it necessary to look abroad for overseers to superintend their operations.

* * *

According to the preliminary statistics accompanying the Medical Register for 1884, the total number of registered medical practitioners in Great Britain and Ireland at the commencement of the year was 24,517 against 23,801 at the beginning of 1883, showing an increase of 716 during the twelve months. The new Dentists' Register contains 5291 names against 5252 in the previous one.

* * *

The last number of the *Moniteur de la Pharmacie* reports the arrest of a woman who was in the habit of obtaining the supply of laudanum for which she craved by presenting at a pharmacy a prescription, concocted by herself, ordering some pills and sixty grams of laudanum. The laudanum she as a rule succeeded in taking away with her, requesting that the pills might be sent to an address, which of course turned out not to be her residence. Seventeen pharmacists appeared to have received a visit from this swindler, who obtained from them jointly about a kilogram of laudanum. Another case reported in the same journal is that of a boy, aged fifteen years, who poisoned himself with prussic acid obtained by means of a prescription fabricated by himself. These cases are worthy the attention of *doctrinaires* who see a solution of the poison question in a provision making the supply dependent upon a medical order.

* * *

At the conclusion of the inquiry at Cheltenham, during which some interest turned upon the dispensing of certain prescriptions ordering oil of savin and liquid extract of ergot (see before, p. 754), the jury returned a verdict that the deceased woman died from blood poisoning, but that although the case was surrounded with very grave suspicion as to the conduct of the medical man who attended her, there was not sufficient evidence to show the cause of the blood poisoning.

* * *

Mr. Saunders, of London, Ontario, states that he has recently had submtted to him for examination two samples of oil of cassia, one of which he found to be adulterated with 50 per cent. of a mixture of castor oil and spirit and the other with about 30 per cent.

* * *

It is announced that the International Health Exhibition will be opened by the President, H. R. H. the Prince of Wales, on Thursday, the 8th of May.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

EVENING MEETING.

The fifth meeting of the present session was held in the Society's Rooms, 119A, George Street. Edinburgh, on Wednesday evening, March 19, at half-past eight o'clock.

Mr. John Nesbit, President of the Branch, in the chair.

The minutes of the former meeting were read and confirmed.

The first paper read was on—

Tincture of Hyoscyamus.

BY WILLIAM GILMOUR.

The paper is printed on p. 781, and gave rise to the following discussion:—

Mr. Stephenson, in proposing a vote of thanks to the author, said he was particularly pleased to hear that the spectroscope test for this tincture was now discredited, for it was one which pharmacists, as a rule, had not the means of applying. He was not surprised that rectified spirit had failed to give so good a tincture as proof spirit; if the active principle of the leaves existed in the natural juice, then he took it that an aqueous menstruum, containing sufficient alcohol for preservation, would be the most reasonable in the circumstances. These proof spirit tinctures of green leaves were often green when prepared, just as the rectified spirit tinctures, but this colour changed to brown after a short time. He was glad to learn that the biennial leaves were the better. This was corroborative of existing opinion, and it might be recollected that Mr. Donovan had started his investigation in the belief that biennial hyoscyamus was quite inert, but he had not gone far before he found that his opinion was based on experiments with annual leaves, so that when he came to try the biennial he found that they were quite active medicinally.

Dr. Inglis Clark seconded the vote of thanks, and said that the paper was thoroughly practical, and the meeting was greatly indebted to Mr. Gilmour for the interesting manner in which he had communicated his results. Regarding the potency of the annual leaves, he recollected that the late Professor Christison stated in his class lectures, that as grown in some parts of the country they were quite inert, while in others they were potent. He asked if Mr. Gilmour had made any experiments as to the alkaloidal value of the leaves.

Mr. Young remarked that the tincture from the annual leaves was quite different in odour and taste from that prepared from the biennial. Were there any ready means of distinguishing between the annual and biennial leaves?

Mr. Gilmour said that the annual leaves were of a paler colour, and, as Mr. Young had observed, the tincture was different from the other. He had not time to determine the alkaloidal value. The annual undoubtedly contained hyoscyamine, for most of that alkaloid prepared in Germany was obtained from the annual. In referring to some samples which were exhibited, he asked if anyone could explain why the tufted variety of the biennial leaves had now almost disappeared from the market. At the present time most of the biennial variety was received in a chopped condition from the wholesale houses; this was somewhat unsatisfactory, since it favoured adulteration.

Mr. Young stated that the tufted variety used to be more plentiful in Scotland, where it was grown for the market there. This was not the case now, but he would like to see more of the tufted leaves, because there was a feeling of security in using them.

The President moved a vote of thanks to Mr. Gilmour for the specimens which he had presented to the Museum.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The tenth general meeting of the thirty-fifth session was held at the Royal Institution, February 28. Mr. Edward Davies, President, in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations to the Library were announced:—The *Pharmaceutical Journal*, from the Society; The *Canadian Pharmaceutical Journal*, from the Editor; The *Science Monthly*, from the Editor.

The President read a letter, dated February 18, which he had received from Mr. A. H. Mason, resigning his office as Vice-President of the Association, owing to his early departure for Canada.

The President said that the subject of Mr. Mason's letter would be brought before a meeting of the Council, and probably further alluded to at the next ordinary meeting.

Mr. Davies drew attention to a statement in the newspapers in reference to the recent explosion at a London railway station, in which it was stated that an officer had tried to obtain from two chemists lignic acid and not being able to procure the same, he employed a razor to show that dynamite had been used. He (Mr. Davies) said that he was not aware of any such compound as *lignic acid*, nor could he imagine how a razor could give any clue as to nitro-glycerine having been exploded. It was possible that the razor might have been acted upon by nitrous fumes; but he was at a loss to see how this fact could be taken as a satisfactory explanation of the presence of dynamite.

Dr. Symes was then called upon to read a paper entitled "Notes on Pharmaceutical Apparatus." The paper was illustrated by a photograph and drawings.

The paper will be found printed on p. 783.

Mr. Conroy, in proposing a vote of thanks to Dr. Symes, said he had listened to the paper with great interest, and had derived a good many valuable hints from it.

Mr. T. Fell Abraham, in seconding the vote of thanks, thought that no difficulty would be experienced in consequence of the outlet from the steam filtering funnel not being at the bottom, the conductivity of copper being so high.

Mr. A. C. Abraham, in supporting the vote of thanks, remarked that the gauge pipe shown would be of advantage when the observer was opposite to it, as from the sides it was no more distinct. He took exception to the term steam funnel being applied to the one described, which was a hot water or steam *filtering* funnel, and quite different from the apparatus to which the other name was applied, either formerly or recently by himself. The head of the still figured struck him, as it had Mr. Conroy, as being very antiquated, but there might still be something to be said for that design, which was probably in use in Egypt two thousand years ago.

The vote having been put from the chair, was carried unanimously, and Dr. Symes having briefly replied, the meeting terminated.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The annual dinner of the Society was held in the Freemasons' Hall, Surrey Street, on Wednesday evening, March 19, under the Presidency of Mr. J. Preston. A goodly number of the members were present.

Letters of apology were read from Mr. A. H. Allen, F.I.C., F.C.S., Borough Analyst, and Mr. Edward Binks, Lecturer on Botany at the Sheffield Medical School.

After the removal of the cloth, the following toasts were proposed and duly responded to:—"The Queen" and "The Royal Family" were given from the chair.

Mr. J. T. Dobb, in rising to propose "The Success of the Pharmaceutical Society of Great Britain," said he regretted business was in a very depressed condition, and the outlook for chemists and druggists gloomy. The physician, the surgeon, and the apothecary, the barrister, solicitor, and the clergy, had all to pass an examination to prove their fitness before they were allowed to practise their several professions. When that examination was passed, the law stepped in and protected them from the quack, the charlatan and the pretender or anyone not duly licensed to practise. Is it so with the pharmaceutical chemist and druggist? No! Before they can open shop to dispense, sell or retail drugs, they must, equal with the above-named professions, pass a strict examination in chemistry, botany, materia medica and pharmacy, and prove their qualifications. Are they protected in their vocation after the requirements of the law are fulfilled? No! Grocers, drapers, tinkers and tailors, stores and jacks of all trades in every town and city step into the arena, and sell all the pharmaceutical preparations and drugs, save a few scheduled poisons. Ah! even "poisons," if they have paid the $1\frac{1}{2}d.$ stamp duty to the Government. Is there a chemist in Sheffield who makes £5 a year out of the A scheduled poisons? Of what use then is the Pharmacy Act? It is no protection to the public and very little benefit to the man who has spent his time and money to qualify himself scientifically to deal competently with the drugs and chemicals required by the public. If the compound preparations of the Pharmacopœia were scheduled, and none but those who had passed through the required examinations should sell retail such articles, then it would be a protection to the public that due care had been taken in the preparation and in the dispensing and vending of these chemicals and drugs, and it would induce well educated youths to enter a business where there would be some prospect of success in life. He ventured to make some remarks of this nature at Chatsworth, at the time the Pharmaceutical Conference visited Sheffield. The *savans* at that meeting turned a deaf ear to such vulgar notions as commerce and how a chemist was to earn a living; nothing but science and education could be taken up by the Society. The question had developed into one of intensity since that day, and had become an important factor in considering the position of the trade. He was pleased to find that Professor Attfield, by two recent speeches, now published, appeared to have grasped the subject. He trusted his views would be laid hold of by the Executive of the Pharmaceutical Society, and that the result would be continued success and prosperity to that body, and that all the branches of the profession would participate.

Mr. W. Ward, in responding on behalf of the Pharmaceutical Society, said he presumed he had again been singled out on account of his occupying the post of Local Secretary. On the present occasion he most heartily acquiesced—the proposer of the toast having referred to the Society in more gratifying terms than he had sometimes listened to at their annual gatherings. It had been his lot on more than one occasion, in replying to the toast, to defend the action of the Council from attacks which had been made, often based upon ignorance, as he had been able to show. Still there was a good deal of complaining that the Society had failed in giving that attention to some of the grievances which undoubtedly existed in their midst. Mr. Dobb had referred to the want of better protection of the trade and the apathy of the Council. He could not but join issue with him. Undoubtedly one of the primary objects aimed at in the Act of Incorporation was not only the advancement of pharmacy, the promotion of a sound system of education, and the safety of the public, but "the protection of those who carry on the business of a chemist and druggist." He should be delighted to see the Council displaying more energy in this direction. The recent poisoning case by infants' mixture in their town was one amongst some of the evils that existed, and which, he considered, should be dealt with by the Council. He thought the Act was sufficiently clear to gain a verdict, and, if not, it would be but another proof of the great importance of stopping the wholesale vending of poisonous preparations by unregistered men. After referring to the action of the Council with respect to the Amended Pharmacy Bill and urging the members to aid the Benevolent Fund, he begged to thank them for the way in which they had drunk to the Pharmaceutical Society.

Mr. Furness, in proposing "The Trade Association," said the Chemists and Druggists' Trade Association had been in existence ten or twelve years. It was established (not to be antagonistic—but as an aid—to the Pharmaceutical Society) more especially in accomplishing work which that Council were either unable or unwilling to perform. It had justified its existence by the good useful work it had done under considerable difficulties, and, of which, he should leave Mr. Jervis to give an account when responding to the toast. His position as a member of the Executive of the Trade Association made him better able to deal with the matter. However, he might say there was still plenty of work to be done, and suggested the Association might, with advantage, direct its attention to the recent case of poisoning by infants' mixture in the town, where the drug had been supplied by a grocer and proved to contain opium. He had reason to believe that infringements of this character were as numerous as they were dangerous to the public, and damaging to chemists and druggists. It was unsatisfactory to learn from the last Annual Report, that the Association was limited in its usefulness by want of funds. It was doing good work and was worthy of more support than it received. That this should be the case was another proof of the gross apathy existing among their fraternity, seeing that only about 4000 out of 13,000 entitled to join availed themselves of its advantages. This was about the same proportion that joined the Pharmaceutical Society's ranks, and he believed that substantially they were the same members, that was to say, there were not 4000 members of this Association, and another 4000 members of the Pharmaceutical Society, showing 8000 as taking an interest in their self-improvement and self-defence, but only about 4000 or one third of the whole body, who would voluntarily take any steps to avail themselves of representation and protection unless when individually assailed, and these outsiders were the biggest grumblers. It was a deplorable state of things, and admitted of no excuse, because whoever did not approve of the Pharmaceutical Society's work might fairly join the Chemists and Druggists' Trade Association of Great Britain, which toast he had the pleasure of proposing.

Mr. Jervis, in responding, said that the Association did its utmost in defending the interests of the chemist or druggist. As a member of the Executive and of the Law Committee, he could state that the Association which he had the honour to represent had nobly done its duty, and he would specially mention the Shepperley case—a case of itself, he maintained—had been of incalculable benefit to every chemist and druggist in the land, and if they had not been enabled to take that case into court and carry it through till victory crowned their efforts, not a chemist or druggist dare ever have prescribed or recommended the most simple remedies for the cure of a disease, no matter how simple, and, in fact, he would have been debarred from exercising a right which any old woman not having the title of a chemist could claim. He could safely say that if any clear case of infringement of the Pharmacy Act, if represented to them, would receive earnest attention and consideration; in fact they wanted work, and if the great body of the chemists would only rally round them he was sure they could be of immense benefit to them. He held that they could do a work which the Pharmaceutical Society could not undertake. He thanked them for the confidence reposed in the Association.

Mr. Jacques proposed the Sheffield Pharmaceutical and

Chemical Society, which was appropriately responded to by Mr. Cubley.

In proposing the Local Educational Institutions, Mr. Ellinor said he hoped the time would soon come when Sheffield would be one of the best instead of being at the bottom of the list; that the enlargement of Firth College and its extension would be the means of combining the education of medical, dental and pharmaceutical students, and that a full curriculum might be provided, in the which a medical, dental and pharmaceutical practitioner would be responsible for the attendance and signing up of each of their respective students. Coupled with this toast, Mr. Ellinor named the other educational institutions and the Central Higher (Board) Schools.

Mr. Garnet responded.

Mr: Ward proposed the President, which was suitably acknowledged by Mr. Preston.

Mr. J. Marshall had the pleasure of proposing the toast of the Vice-Presidents and Council of the Sheffield Pharmaceutical and Chemical Society. He said all would heartily join in drinking their health, because it was well known how careful they were to take up any matter which might deserve their attention, and the energy they displayed in carrying out any worthy object. He regretted that the Council did not meet with the support which they might reasonably expect. In looking at the small annual subscription (5*s.*), he said there could be no excuse for non-membership. He considered that the chemists and druggists stood very much in their own way; they wished for protection in their calling, and when this was necessary, who were more ready to call out than those who held aloof? There was no doubt about the Society doing good. The Council were now carefully watching the much to be regretted state of affairs (the many poisoning cases), and would no doubt do what all wish to be done when the right time is at hand. He remarked how necessary it was for all to be united at a critical time like this. He had noticed how the Council had frequently taken up matters which concerned all chemists aud druggists, and had often sent up resolutions and suggestions to the Pharmaceutical Society which had been respected, and would still be more so if all were to attend the meetings and use the power which they possessed. The junior members had great reason to be thankful to the Council for their help in connection with their studies, especially for the free use of the Society's rooms and library, and in the many ways in which they had shown their interest in the welfare of the younger ones, and he had no doubt but that they (the juniors) would still have their influence (both collectively and individually), and help to obtain admission to the Local Botanical Gardens. He had great pleasure in coupling with the toast the names of Mr. Watts and Mr. Furness.

Mr. Furness responded.

Mr. Dobb proposed the toast of the "Treasurer and Secretary," which was replied to by Messrs. Jervis and Newsholme.

Mr. Fox proposed the "Assistants' Association," to which Mr. Smith responded as follows:—The introduction of this toast is an honour the Junior Association has reason to be proud of, and I respond to it with much gratification and pleasure. Being so recently inaugurated we have no extensive history to review, but looking forward there are signs of an increasingly useful and successful career for this Association. The classes are well attended and most satisfactorily conducted, and, when we consider the number of students, and the distance many have to come who attend, together with the fact that the only attraction is that of an intellectual nature, I think we have a proof that good and real work is being done. The Association has increased the number of members in your Society, and I would suggest in return that some of the papers read at the monthly meetings be specially addressed to the students, papers tending to produce a familiarity with the ways of Bloomsbury Square,—the very name of Bloomsbury Square being a terror to many provincial students—a familiarity being productive of confidence, which is half the battle. The obtaining of permission to use the Botanical Gardens, I think we may well leave to the Council. Such permission is most desirable and needful. To the Council also we would tender our warmest thanks for the great help they have given us and for the lively interest they take in our proceedings.

After the complimentary toast of the "Visitors" had been proposed and responded to, the meeting, which was continued to an early hour in the morning, separated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, March 20. Dr. W. H. Perkin, President, in the chair.

The following certificates were read for the first time:—Messrs. W. D. Borland, A. F. Dimmock, J. Gaskell, W. H. Perkin, jun., A. G. Perkin, and J. W. Pratt.

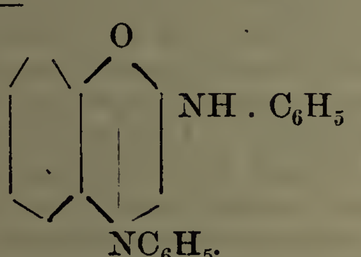
During the evening a ballot was held and the following gentlemen were declared by the Scrutators, Drs. P. Frankland and Morley, duly elected Fellows:—Messrs. F. W. Brown, H. Cave, F. W. Fleming, E. E. Graves, A. E. Lewis, J. E. London, G. A. Parkinson, S. Smith, G. Tunbridge, and T. U. Walton.

Mr. Tribe then read a note—

On the Preparation of Marsh Gas. By J. H. GLADSTONE and A. TRIBE.—In 1873 (*Chem. Soc. Journ.*, xi., 682) the authors described two reactions, in which marsh gas was produced free from other hydrocarbons by the action of the copper-zinc couple on methyl iodide in the presence of water or alcohol. The loss of methyl iodide was, however, considerable, varying from 23 per cent. to over 50 per cent. In the present note the authors describe a slight modification of the apparatus, by means of which this loss can be prevented. About 600 grams of thinly granulated zinc are immersed in a 2 per cent. solution of copper sulphate until the latter is decolorized. The copper-zinc couple is washed with water and finally with alcohol; it is introduced into a flask, the mouth of which is closed by a doubly perforated cork. Through the cork pass the end of a stoppered funnel containing the methyl iodide, and the end of an upright wide glass tube, 12″ long and 1″ in internal diameter, filled with copper-zinc couple. The upper end of this tube is also closed by a doubly perforated cork, into which fit a delivery tube and the end of a stoppered funnel containing alcohol. This upright tube serves the double purpose of a copper-zinc scrubber and an inverted condenser. A mixture of 20 c.c. of alcohol and 20 c.c. of methyl iodide being allowed to run into the flask, a steady evolution of marsh gas proceeds; the first litre was evolved in eight minutes, 7053 c.c. were obtained, the theoretical yield being 7100 c.c. The reaction can be much expedited by gently heating the flask.

The Secretary then read a paper—

On the Action of Dibrom-α-Naphthol upon Amines. By R. MELDOLA.—In a preliminary note (*Chem. News*, Jan. 19, 1883) the author called attention to the remarkable facility with which dibrom-α-naphthol entered into reaction with certain amines, forming, in the case of anilin, paratoluidin, and β-naphthylamin, well characterized crystalline bases. The action of this dibromnaphthol upon diamines has been made the subject of a patent by L. Casella and Co. (*Germ. Pat.*, No. 20,850), and the reaction has been investigated by R. Möhlau (*Ber.*, 1883, 2853). The author, therefore, confines himself to a description of some results of the action of dibrom-α-naphthol upon monamines. On mixing dibrom-α-naphthol with about three times its weight of aniline, a white crystalline mass of aniline dibromnaphtholate is formed. On heating to nearly the boiling point of aniline, the contents of the flask acquire a deep reddish brown colour; the reaction is complete in about ten minutes; when cool the mass forms a solid cake of crystals. The substance was purified by washing and recrystallization from boiling alcohol and formed orange red needles melting at 179°, it possessed basic properties and agreed with the diphenyldiamidonaphthol of Goes and of Tincke. The zinc and platinum salts were prepared and analysed and the identity of the substance with β-naphthoquinonedianilide conclusively established. With orthotoluidin a similar reaction took place, but nothing separated out on diluting the contents of the flask with alcohol. With paratoluidin similar results were obtained and the product crystallized out in silky orange needles melting about 175°. A crystalline body was also formed when α-naphthylamine was used. The action of dibrom-α-naphthol upon amines, therefore, furnishes a most simple method of obtaining these quinone-imide derivatives in large quantities. The author then discusses the significance of this production, as affording an insight into their constitution and considers that the constitution of β-naphthoquinonedianilide must be—



The Secretary then read—

A Note on the Existence of Salicylic Acid in the Cultivated Varieties of Pansy and in the Violaceæ generally. By A. B. Griffiths and E. C. Conrad.—The authors have extracted colourless acicular crystals from pansy leaves, etc., soluble in ether, alcohol and boiling water, which gave with ferric chloride a violet colour. A combustion gave numbers agreeing with the formula of salicylic acid. The leaves yielded 0·13 per cent., the stems, 0·08 per cent., the roots 0·05 per cent., whilst the flowers contained only a trace. The authors cut sections of the leaves, etc., but failed to discover any crystals of salicylic acid in the cells.

The Society then adjourned to April 3.

The Anniversary Meeting will be held on Monday, March 31.

SOCIETY OF ARTS.

Alloys used for Coinage.

At the commencement of the second lecture of the Cantor series upon "The Alloys used for Coinage," Professor W. C. Roberts explained the use of several terms not always clearly understood. The terms alloy, allay or lay, are generally applied to characterize the base metal used in the mixture, and not, as correctly they should be, to the mass itself, the term was most probably derived from the Latin *adligo*—to bind to, or a Teutonic word meaning to lessen. Though the terms sterling and standard are now almost synonymous, yet formerly the term sterling was used to distinguish a special alloy of silver and copper of a higher degree of purity than the standard. The standard of fineness is a term employed to designate the amount of pure metal in an alloy, and is now almost universally calculated to the decimal method; nations now maintain a nearly equal "standard of fineness" in order to avoid loss and facilitate commerce. For the purpose of melting the metals and mixing the alloys, crucibles composed of graphite and fire clay are employed; the crucibles used for melting gold hold about 1200 ounces and those for melting silver about 4000 ounces. Coke is generally used as the heating material, although in Berlin, the crucibles are heated by means of gas generated in a retort in direct communication with the furnace. Reverberatory furnaces are only used in the melting of bronze, as the loss of the rarer metals owing to leaky hearths would be too large to allow their use. It is necessary that alloys should be so prepared as to ensure rigidity, durability and uniformity of composition; it is further imperative that the alloy shall be able to *flow* easily into the finest lines of the engraved die when struck. The "fineness" of the alloys can be tested by means of an electric current, on which test the lecturer expressed his intention of speaking more fully; it is also noticeable that both the ring is clearer and the rigidity greater in the case of the standard alloy than in that of the pure metal. Copper is found most convenient to alloy with gold, as the colour is rather heightened than lessened by the admixture; the reverse is the case when silver is used, for if the alloy contain more than one-third of silver the colour of the gold is completely lost. The use of triple alloys has been suggested, but this would only lead to more intricate details. Professor Roberts then entered into an explanation of the differences of the troy, carat and decimal systems. The carat system was either derived from the Arabs or from the Roman mint; the decimal system, first employed on the Continent in 1794, was not introduced into England till 1882. The lecturer then gave a number of tables showing the changes in the composition of alloys from the most ancient times. A Greek coin of about 359 B.C. was found to contain 99·7 per cent. of pure gold, this being the greatest purity obtainable by the method then in vogue; the early British coins (B.C. 50) contained only 40·5 per cent. of pure metal, whilst the Anglo Saxon alloys differed greatly in their "standard of fineness." Since the Norman conquest, however, gold coins have contained nearly the same percentage of pure metal, excepting in the latter part of Henry VIII.'s reign, when it fell as low as 83·3 per cent. The present standard of 91·66 per cent. is also that of British India, Russia, Portugal, etc., whilst that of France and the remainder of the Latin Union is about 90 per cent. In regard to silver coins, they also sustained only one very marked deterioration of standard, falling in the sixteenth century to 25 per cent. of pure metal. The English standard is at present 92·5 per cent., whilst France has two, one of 90 per cent. and the other of 83·5 per cent. Professor Roberts then gave the composition of a number of alloys which had been introduced. That of Peligot consists of 58·1 per cent. of gold, 36·1 per cent. of copper and 5·8 per cent. of zinc; the modern nickel alloy consists of 75 per cent. of copper and the remainder of nickel, whilst the older alloy consisted of 77·6 per cent. of copper and 20 per cent. of nickel, the remainder being made up by small quantities of cobalt and iron. The advantage of these nickel alloys consists in the value of their magnetic properties for testing. Alloys of aluminum have also been suggested owing to their light weight.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above Association, held March 19, Mr. H. M. Hadfield in the chair, a paper on "Essential Oils: their Derivatives and some of their Uses," by Mr. W. A. Wrenn, was read by Mr. H. Cracknell (Hon. Sec.).

The author first mentioned oleum amygdalæ essentiale, giving an account of the collection of the almonds, their habitat, and the amount per cent. of essential oils yielded both by the almonds themselves and also the cake, being ·4 per cent. to ·95 per cent., and ·75 per cent. to 1·6 per cent. respectively, the crude oil having a specific gravity varying from 1·056 to 1·070. The percentage of hydrocyanic acid was stated to vary between 8 per cent. and 12 per cent., the processes for freeing the oil from this acid were mentioned, distillation with red oxide of mercury being given as the most convenient for small quantities. Tests were also given for the impurities in the oil; the pure oil should have a specific gravity of 1·049 to 1·051. Oleum cajuputi was next mentioned. Four samples of this oil having been examined all gave evidence of traces of copper. The author had submitted four samples to redistillation, and in all cases obtained a colourless product, having a specific gravity of ·916 to ·918. Oleum caryophylli next received attention, the various sources of the oil being alluded to, and the product stated to be from 12 per cent. to 22 per cent.; the distinctive characters of the oils distilled from the flower buds and the stems of the plants were enumerated. A short account of oleum copaibæ essent. was then given, the quantity yielded from the balsam varying from 36 per cent. to 60 per cent.; the Para balsam yields by far the largest amount of oil, and the oil thus obtained has the best aroma. The specific gravity varies from ·878 to ·900. Oil of turpentine is the chief adulterant of this oil, and may readily be detected by its relative solubility in alcohol. The boiling point of oleum copaibæ is very high, being about 500° F. Oleum cubebæ was then alluded to. The drug is now causing a little sensation in the market on account of the very high price which is obtained for it. This is supposed to be due to the great demands from America, where it is now largely used in catarrhal affections of the air-passages. The product of oil from the fruit is about 7 per cent. to 12 per cent. The specific gravity is from ·924 to ·929. Oleum juniperi, oleum santal. flav., and oleum sassafras were all briefly mentioned, and the paper was brought to a conclusion with a few remarks on the two varieties of wintergreen oil, viz., that obtained from *Gaultheria procumbens*, the American source, and that obtained in East India from *Gaultheria punctata*.

Parliamentary and Law Proceedings.

House of Commons.

Patent Medicines Bill.

In the House of Commons on Wednesday, Mr. Warton in moving the second reading of this Bill, remarked that in bringing the subject of patent medicines before the House he had two objects in view. In the first place he wished to point out that the Government stamp gave undue prominence to patent medicines and induced people to take that which was injurious to them. Many people who read patent medicine advertisements believed that both Houses of Parliament had in some way sanctioned and almost sanctified those medicines. He submitted that it was very wrong for the Government to derive any revenue from such an unworthy source. When this question was last before the House the Under-Secretary for the Home Department said he could not make any promise as to what the Government would do in the matter, but he hoped that some better system than that now in force would be adopted. The Government, however, had done nothing at all, and it appeared to him that whatever course they adopted they were in favour of spreading disease. In his opinion it was the duty of the Government to bring this subject forward because they alone could deal with the fiscal part of the question. The second object he had in view was to show that patent medicines contained poison. Many persons had died through taking those medicines. The man who recklessly sold them was little better than a murderer, and the Government who failed to take measures to alter such a state of things connived at murder. What was the use of analysing those medicines when a poor child—for children were generally the victims—or a poor woman was dead? What he wished was that some feeling should be shown for these poor women and children so as not to have them poisoned by quacks. By the Pharmacy Act of 1868, the Pharmaceutical Society had the power of declaring what were poisons, and, when any new drug with poisonous properties was brought to light, of inluding it in the list. The Society was to pass a resolution to the effect that a certain drug was a poison, that resolution was to be submitted to the Privy Council, and if the Privy Council approved it was to be published in the *London Gazette*, and thenceforth the article so named became a poison under the Act of 1868. The effect of that was that any person going to a chemist's shop and asking for arsenic or any other drug in the list of poisons had to give his or her name and address and answer a variety of questions. But one might buy patent medicines in bottles 18 inches high and 12 inches wide containing an immense amount of poison, and the curious part of the Pharmacy Act was that the rights of the proprietors of patent medicines were carefully preserved. Now, he was for preserving vested interests, but there was one vested interest he would not preserve and that was the vested interest in poisoning people. At present one might buy these poisonous medicines by wholesale, not only in the shops of chemists, where there were generally gentlemen of education and responsibility, but in grocers' and petty village shops. His Bill provided that any person who was the owner or proprietor of a patent medicine might have his medicine analysed by the Pharmaceutical Society, and so in like manner any respectable chemist who sold patent medicines, or persons who bought them might have them analysed by the Pharmaceutical Society. If it was found that the medicine contained poison let the Pharmaceutical Society pass a resolution similar to that provided by the second section of the Act of 1868, and let them state that "this elixir"—for that was the favourite word—contained poison, and the resolution having been approved by the Privy Council, let it be published in the *London Gazette*, and after that the medicine became a poison subject to the restrictions of the Act. He thought that the Government might put aside their political nostrum of the Reform Bill for a time and attend to the lives and health of the people.

Dr. Farquharson considered that there was little need for saying much to urge upon the House the necessity for legislation of this kind, as the Government themselves had shown their appreciation of the importance of the subject. It was an absurdity to fence round the sale of poisons, when any one could, by putting a Government stamp on the bottle, sell any farrago of poisonous stuff. Great loss of life and health was caused by the sale of these patent medicines, as was shown by the Registrar-General's report. In 1881 there had been twenty deaths from the use of chloral hydrate, two from Godfrey's cordial, one from anodyne cordial, eight from chlorodyne, one from aniseed, one from Stather's soothing syrup, and fifty-one from patent medicines the names of which were not stated. It was certain, moreover, that these deaths could not possibly indicate the amount of loss of life caused by these deleterious substances. There had been a great increase in the consumption of patent medicines since teetotalism had become fashionable. There was a great demand for pick-me-ups and cordials, and there was no doubt that an enormous quantity of chloral was consumed by ladies. It was impossible altogether to check the sale of these patent medicines, although he himself would like to see a sweeping Bill on the subject. All medical men detested secret remedies, but of course it was impracticable to suggest any sweeping measure. There were great vested interests in the way, and the British public was fond of domestic medication, and even of a little quackery. What they had to do, then, was to regulate the sale of these medicines as best they could. This Bill was founded on French lines. In that country a medicine could not be stamped until it had been officially analysed, but the regulation was frequently evaded, in fact, unless the analysis were repeated every week or so, it would be of little use. He would suggest one or two alterations in this Bill. The word "proprietary" should follow "patent," so as to include unstamped mixtures, frequently containing deleterious ingredients, which were sold to a large extent in villages where there were no druggists' shops. Then there was a difficulty as to the analysis of the Pharmaceutical Society that it would only refer to statutory poisons, without including preparations which, without being absolutely poisonous, were on the borderland. Another objection was that the sanction thus given by the Pharmaceutical Society would largely increase the use of these patent medicines. He would recommend that the Government should harden their hearts and give up the patent medicine stamp, which brought in £154,000. This might, in his opinion, be made up by an increased charge on the licences for the sale of these drugs. Under the present system the Government stamp implied to many ignorant persons a direct sanction and a patent which did not exist. The stamp might be used for any preparation composed of more than one ingredient and recommended for some specific purpose which was only liable under the excise laws. A second recommendation which he would make would be that every proprietor of a patent medicine containing poison should be obliged to put a label with the word "poison" on the bottle and wrapper, with a direction that such medicine must be prescribed with caution. This caution might be extended to substances of injurious, if not directly poisonous, nature, such as teething powders, which contained mercury and opium. Then, again, the innocent seller should have a remedy against the proprietor and manufacturer. If the proprietor failed to put the word "poison" on the bottle, the Pharmaceutical Society might be called on to analyse the medicine, the cost to be paid by the proprietor in the event of its being found to contain poison, with penalties recoverable under the Pharmacy Act. The most important part of the Bill was the 5th section. It was absurd that when such precautions were taken under the Pharmacy Act anything might be sold when labelled as a patent medicine at any grocer's or at any stores. He thought it was anomalous that the druggists should be hampered by restrictions which were not imposed on stores. He further submitted that powers should be vested in the local authorities to enable them to undertake prosecutions under the Pharmacy Act as under the Adulteration of Food Acts. Those prosecutions at present were undertaken by the Pharmaceutical Society, thereby bringing upon it, on occasions, unmerited obloquy. In conclusion, although he could not agree to all its provisions, he thought the House owed a debt of gratitude to the hon. member for Bridport for bringing in the Bill.

Mr. W. James asserted that the preamble of the Bill, reciting that many deaths had occurred from the use of patent medicines, had not been made out. During the last two years not more than seven deaths had arisen from the use of these patent and proprietary medicines, against one hundred and fifty-two deaths caused by drugs sold by chemists, the use of which resulted in death by suicide, misadventure, and other causes. A boy died last year who had been taking Holt's whooping-cough specific, but the medical man admitted that he merely guessed that death was due to the effects of antimony contained in it, and it was almost impossible to say whether death was caused by the antimony or by natural causes. The matter was too serious and far-reaching to be treated in a private Bill; if it was taken up at all, the Government should deal with it. The present Bill was utterly unworkable, and would inflict great hardship on an immense number of persons. There were no less than from eight hundred to one thousand owners of these proprietary medicines, nineteen thousand people were employed in their manufacture or sale [Mr. Warton: So much the worse], they brought in £150,000, and thirty million packets were sold in the course of a year. Under these circumstances he did not think the Bill ought to be supported by the House, and he therefore moved that it be read that day six months.

Mr. Hopwood, in supporting the motion, doubted whether any legislation of this character had been productive of any real benefit to the community. He believed the Sale of Poisons Act had done no good, its effect being only to delude the public and to vex a number of honest men in their employment. Such legislation further tended to create a medical monopoly, and something of the feeling of trades unionism might be detected in the hostility shown by coroners and medical gentlemen towards patent medicines when the deceased had been shown to have lately used them. If these medicines were deleterious, the producers of them ought to be answerable to the common law.

The Attorney-General said the Government could not assent to the second reading of the Bill, although it was introduced with objects with which any one might sympathize; but it was necessary to look to the means proposed for the attainment of those objects, and, doing this, the Government could not accept the provisions of this Bill, which would treat as a poison any medicine containing any poison, however innocuous the quantity might be in the preparation of which it formed part. The Government had the matter in hand, and was prepared to treat it in a much broader sense in a Bill which would be introduced into the other House, and when it reached this House he hoped the desire of the hon. member for Bridport for legislation on the subject would induce him to stay his obstructive hand, and that his own introduction of a Bill would constitute a sort of implied contract with him for the adoption by him on this subject of a course, the novelty of which would be fully appreciated by the House. But the Bill of the hon. member could do no good and must do evil by harassing people unnecessarily; for, in this respect, it would constitute one of the most flagrant specimens of the kind of legislation against which the hon. member frequently protested.

Mr. A. O'Connor said if he approached the consideration of the subject without bias he should be inclined to support the Bill, for he had not been convinced by the arguments used against it, and it was admitted that illness and death were caused by patent medicines. He failed to see that the subject required such large treatment that only the Government could deal with it. If the Bill would be beneficial in its operation, he could not understand why Ireland was to be excluded therefrom.

Mr. Warton said that the reason why he had excluded Ireland was that he did not know what body in that country would take the place of the Pharmaceutical Society in Great Britain; and he had but followed the wording of the Pharmacy Act. The case of the widows and orphans who were interested in the sale of patent medicines could scarcely be put forward seriously against the safety of the public. The hon. member for Stockport's objections applied not so much to the Bill as to the doctors, whose alleged monopoly, especially as regarded vaccination, he was always opposing; but, as even medical coroners occupied an independent position, the suggestion that they conducted their inquiries with a bias against patent medicines, was an unworthy imputation. With regard to the argument put forward by the Attorney-General, he thought they might trust the Pharmaceutical Society not to brand a medicine as a poison unless it was really poisonous. Unless the quantity of the deleterious ingredient which it contained rendered the medicine poisonous, he did not want it to be branded as a poison. He was glad that the result of the motion which he brought forward on that subject two years ago had been so far beneficent that the Government were now pledged to introduce into the other House a bill relating to it; and he hoped that the Chancellor of the Exchequer would consent to abandon as a source of revenue the stamp duty now payable on medicines of that sort, which was supposed to give them the sanction of the State. Unless the Government gave him a positive pledge that they would deal with the fiscal question as well as with the other part of the subject, he should feel compelled to take the sense of the House on that measure, in order to show that that was a question of great importance which had been too long shelved and neglected.

The House was cleared for a division, but ultimately the second reading of the Bill was negatived without one being taken.

SUPPOSED DEATH FROM TAKING CHLORODYNE.

On Monday, the 17th inst., Mr. T. C. Brian, the Plymouth Coroner, held an inquest relative to the death of Christopher Snell.

The wife of the deceased said that her husband was 64 years of age. For a year or so his health had not been very good, although, on the other hand, he had not been so unwell as to require medical aid. For about five years he had suffered from a cough. Witness had given the deceased chlorodyne since the previous Tuesday. She usually administered ten or twelve drops in the evening, but she discontinued it on Friday because she thought the cough was better. Witness was certain that he had not taken any chlorodyne without her knowledge. Her reason for discontinuing the chlorodyne, was because he seemed stupid. Now that her attention had been called to it she fancied that the deceased had seemed drowsy after every dose. She had bought this medicine at Messrs. Wills, Son and Box, in George Street. Deceased died in a stupor, but complained of a pain in his side.

William Henry Andrews said that the deceased had often spoken of his cough. On Tuesday evening witness was at the house, and the bottle of chlorodyne was produced, when the deceased requested him to read the directions. He did so, and poured out ten drops, and having put them into half a glass of water gave them to the deceased. On Wednesday he had two similar doses. The directions stated that the dose must be given when the cough was troublesome.

Mrs. Snell, recalled, stated that it was a fact that the deceased took the dose twice in one day; it was given him by her son.

The inquiry was adjourned until Wednesday in order that a *post-mortem* examination might be made.

At the adjourned inquest, the widow, recalled, said the bottle of chlorodyne used by the deceased was not kept in the room occupied by the deceased. As far as she knew the medicine had not been touched since she placed it in the kitchen on Friday. When he awoke on the Monday morning deceased was not drowsy. She first saw a great change in him about half-past ten in the morning, and from then to his death she did not leave him.

Mr. E. H. Edlin, surgeon, stated that he had made a *post-mortem* examination. The brain was slightly congested and in a state indicative of disease. The heart was flabby, there being fatty degeneration. The right lung was also in a congested state, indicating chronic pleurisy. There was, however, nothing to account for death under the circumstances described. According to the evidence the deceased did not take a dose of chlorodyne after Friday, but if it had transpired that he had had one on the Friday morning, witness would have considered that with the disease it had accelerated death. Chlorodyne was very poisonous, and contained three distinct poisons, for any one of which, bought separately, the purchaser would have to sign a book at the chemist's shop. He considered it a very unsafe thing.

After a brief deliberation the Jury returned a verdict of "Death from natural causes," adding a rider to the effect that "The Jury consider it is a matter of regret that chlorodyne can be freely purchased by the public, without any kind of restriction."—*Western Morning News.*

THE POSITION OF PHARMACY.

Sir,—"A man of straw," it appears, may sometimes be of very great service; in fact, we are told that even a single straw may play a very important part on the stage of life. My "straw man," in falling, has evidently had an effect upon Mr. Wilkinson, and has restored his equilibrium. A correspondent writes me—"Mr. Wilkinson must either have forgotten what he wrote first or else he does not know the English language." Another says, "Mr. Wilkinson's second letter is strangely at variance with his first."

Now I do not suppose that either of these gentlemen have hit the mark. Mr. Wilkinson's first letter was the outward and visible sign of an inward organic disturbance, that has now passed away (hastened in its departure possibly by the shock occasioned by the fall of "a man of straw"); his second letter is the result of a fast returning convalescence, so that we may now, I think, safely leave him, assured of the fact that instead of a vigorous opponent the Council has, as hitherto, a loyal and intelligent supporter, and what you, sir, and most of us thought was a weakness "in the chain" has turned out to be only a little rust which has been rubbed almost entirely off by a "bit of straw."

Before bidding Mr. Wilkinson adieu, kindly allow me to say that if he does not really "know of any to whom my remarks apply," he is the only chemist for miles round who does not; and lastly, to quote his own words, as all the members of the Council are chosen by members of the Society, and as year after year the *personnel* of the Council remains almost identically the same, we must suppose that the electors have "chosen those whom they consider the most suitable," and are, on the whole, perfectly satisfied with them. Your Stockport correspondent I would advise to apply the advice of Jupiter to the gentleman who prayed him to assist him out of his difficulty, and I would say to him, *Qui s'excuse, s'accuse.*

131, *Embden Street, Manchester.* J. HART.

Messrs. Bourne, Johnson and Latimer.—The information has been already published that the Inland Revenue authorities have decided that if the preparation consists entirely of pure menthol it will be exempt from stamp duty.

F. R. M.—We do not think any further steps were taken.

J. Thompson.—You will see that the Bill, which did not have the sanction of the Government, has been rejected.

"*Broad.*"—Professor Graham's Lectures on the Chemistry of Breadmaking will be found in vol. x. of the present series, pp. 804, 883, 923, 1028 and 1049.

G. Gordon.—*Lathræa squamaria.* Please attend in future to the instructions on another page as to addressing communications intended for the Editor, and make sure that the stamps affixed are sufficient.

J. Epps.—*Lathræa squamaria.*—It is rather local than rare.

Apprentice.—The solubility cannot be increased to any important extent without additions that alter the character of the compound. See a paper in vol. vii., p. 490.

Errata.—On p. 773, col. i., line 3 from bottom, for "minutes" *read* "seconds." On p. 775, col. ii., line 38 from top, the word quoted from Watts's 'Chemistry' should be "octohedrons," instead of "octahedrons."

W. Mackereth.—Your letter has been handed to the Secretary, to whom all communications concerning the non-delivery of Journals should be sent.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Ball, Bell, Smith, Dott, Williams, Rook, Wyley and Co., Hearder, Sedford, Vulcan.

AQUEOUS EXTRACTION OF CINCHONA BARK.*

BY PROFESSOR REDWOOD.

Among the various forms that have been devised for the administration of cinchona bark, preparations produced by aqueous extraction have always occupied a prominent position. Even since the discovery of the alkaloids, which are the only powerfully active therapeutic constituents of the bark, medical men have not been always satisfied with the use of these to the exclusion of other constituents, and therefore tincture, infusion, decoction, and fluid extract, are preparations which have been frequently employed, and from the use of which effects have resulted which the alkaloids alone have failed to produce. Where water alone is used for extracting medicinal properties from bark, as in the three last named preparations, there is a strong ground of objection to the mode of operating officially authorized in those cases, which is that a great part of the most valuable constituents of the bark operated upon is left in the marc, the menstruum used being incapable of dissolving them, and holding them in solution. This result, with reference especially to *Extractum cinchonæ liquidum* of the British Pharmacopœia, has called forth a good deal of criticism when that preparation has come under discussion; but the defects which have been pointed out and commented upon, as indicated by analyses made both of commercial samples and of samples specially prepared for the purpose, may, in several, and in all the most glaring instances, be ascribed in great part to faults other than those which essentially appertain to the process. It cannot, however, be contended that the process is a good and satisfactory one. Some of our best practical pharmacists have for some time past been seeking, or having found have been applying, processes which are said to yield better results, but unfortunately we have no published account of the investigations which have led to those results.

I have on several occasions endeavoured to induce some of my pharmaceutical friends to undertake the investigation of the best mode of preparing *liquid extract of cinchona*, with a view to publication; but, not having succeeded in that direction, I have made some experiments myself, for the purpose of testing the feasibility of obtaining aqueous extracts of cinchona better suited for use in medicine than those which are at present official.

I started with a decided opinion, founded on previous observations, as to the direction in which the investigation should be pursued, and the objects which it was most important to accomplish. They may be stated as follows:—

1. That the red, or succirubra bark is the sort most suitable for use in these operations.

2. That the extracting liquid should be water, an acid being used to render the active medicinal constituents of the bark soluble in this menstruum.

3. That the bark should be exhausted of its alkaloids in the process adopted, and that the extract should contain such other constituents of the bark as are considered to be medicinally valuable.

4. That the liquid extract should contain a specified quantity, say 5 per cent., of the mixed alkaloids of the bark.

5. That the liquid extract should admit of dilution with water without becoming turbid, and, on the other hand, that it might be evaporated to dryness without impairing its solubility to any appreciable extent.

In view of the numerous discussions that have taken place from time to time with reference to the selection and treatment of cinchona bark in its preparation for use in medicine, it will not, I think, be considered necessary that I should enter here into a detailed representation of the advantages resulting from the accomplishment of the foregoing objects. I will therefore at once describe the process I have adopted, by which those objects appear to be completely, easily and economically carried into effect.

Extract of Red Cinchona.

Take of—

Red cinchona bark, in No. 50 powder	1 pound.
Distilled water	4 pints.
Hydrochloric acid	½ fluid ounce.

Mix and macerate at a temperature of 180° F. for four hours, stirring frequently, and replacing the water that evaporates. Allow the mixture to cool; then transfer it to a percolator, and when the liquid ceases to pass, carefully introduce distilled water over the surface of the solid matter in the percolator, and continue to percolate slowly until ten pints of liquid have passed, or it is found that what is passing has ceased to give a precipitate on the addition to it of an excess of *liquor sodæ*.

Evaporate the percolated liquid, at the heat of a water-bath, until it is reduced to one pint. Let it cool, then add three pints of distilled water; stir them together while a precipitate is forming; separate the precipitate by filtration; well wash the filter and its contents with distilled water; evaporate the whole of the filtered liquid at a temperature not exceeding 180° F. until it has acquired a syrupy consistence, and dry this either in thin laminæ on the surface of glass, or in thicker masses by exposing it in shallow dishes in a drying closet.

Dissolve 20 grains of this extract in a fluid ounce of distilled water and add three fluid drachms of *liquor sodæ*. Mix thoroughly and let it stand for twelve hours that the precipitate may subside. Collect the precipitate on a filter, wash it first with distilled water rendered alkaline with *liquor sodæ*, and, finally with water alone, and when it has drained transfer it to a dish and dry it at 212° F. Its weight multiplied by five will represent the percentage of total alkaloids in the extract.

Liquid Extract of Red Cinchona.

Take of

Extract of red cinchona, as much as contains of total alkaloids.	437·5 grains
Distilled water	A sufficiency.
Rectified spirit	5 fluid ounces.

Dissolve the extract with the aid of a gentle heat in twelve ounces of the water, when cold add the spirit, make up the volume to 20 fluid ounces by further addition of water, and filter.

The principal object in this process has been the production of a liquid extract of known and uniform alkaloidal strength, which, while it possesses the aromatic flavour and astringency of the bark, is free from much inert matter, and from the peculiar extractive (chiefly quinovin) which, in our official liquid extract, forms a dense, unsightly and disagreeable precipitate when diluted with water.

* Read at an Evening Meeting of the Pharmaceutical Society, April 2, 1884.

Hitherto it has been the practice to prepare the liquid extract so that it shall bear a definite relation in volume to the weight of the bark from which it has been made; but as it is practically impossible to ensure uniformity of composition or of alkaloidal strength in the samples of bark employed, the properties of the prepared extract have necessarily differed as widely as those of the barks from which they have been obtained.

The mode of proceeding in this process admits of the use of any but the lowest qualities of the red barks of commerce. The total alkaloids contained in the dry extract produced in the first stage of the process are easily estimated, and the percentage of alkaloids being determined, while the extract itself is soluble in water, there will be no difficulty in ensuring uniformity of strength in the liquid extract. By the process as given it will contain 5 per cent. of mixed alkaloids in addition to the other constituents of the bark that are left in it. Thus a fluid ounce of the liquid extract may be considered to contain all the valuable medicinal properties of an ounce of red cinchona bark of good average quality.

It is obvious that the result indicated could not be obtained without using an acid in addition to that present in the bark, and there is no evidence that I am aware of to show that by causing alkaloids which would otherwise be wasted to combine with 9 or 10 per cent. of their weight of hydrochloric acid and thus become available for use, the efficacy of the resulting preparations would be in any way impaired

The small quantity of hydrochloric acid used in the process is sufficient to ensure the entire removal of the alkaloids from barks of average, and even more than average, quality. I have avoided the use of more than appears to be necessary, because its action with heat is said to be injurious. A slight excess of acid would be dissipated in the final concentration or desiccation to which the extract is subjected. I have ascertained that by following the instructions given the whole of the alkaloids extracted from the bark is within a small fraction contained in the dry extract in a soluble state. These alkaloids are associated in the extract and also in the liquid extract with other constituents of the bark which partake of the general character of some of the extractive matter of the *liquid extract of yellow cinchona* of our Pharmacopœia, but in one respect there is a marked difference between the two liquid extracts. There is nothing contained in the preparations made by this process that is not freely soluble in water, and therefore there is no precipitation or turbidity produced by aqueous dilution.

Having obtained several varieties of the red barks of commerce for the purpose of comparing the results obtained from them by this process, I have observed that they do not all yield the same sort of extract, arising from the fact that some are much richer in quinovin and red cinchonic than others. The thick flat varieties are the richest in those worthless constituents, while the thin young bark which, having been removed from the small branches with a spokeshave, is imported in small chips, is comparatively free from anything that causes turbidity on diluting the first concentrated extract with water.

This result, however, does not interfere with my process. The dilution would still be adopted as a safeguard, and being adopted the final results will then, as far as I have yet observed, be uniform or nearly so.

The formation of dry extract as a preliminary step towards the production of liquid extract was adopted for the purpose of facilitating the adjustment of the alkaloidal strength of the latter; but the properties of this dry extract which is soluble in water, forming a clear solution, will probably suggest its employment for other purposes, especially where the entire absence of spirit may be desired.

In the production of the liquid extract on the large scale, as well as otherwise, it is probable that manufacturers will often avoid the trouble of drying the extract, and stop the evaporation when the liquid contains the specified proportion of alkaloids, or carry it a little beyond the required point and then dilute it to what is required.

There are some experimental results connected with the subject which I have not yet had time to complete, but I have thought it desirable at once to submit the essential features of this process for medical and pharmaceutical criticism, reserving further details for a subsequent communication.

[*The discussion on this paper is printed at p.* 810.]

PROXIMATE ANALYSIS OF THE SEEDS OF AMOMUM MELEGUETA (ROSCOE).*

BY JOHN C. THRESH, D.SC.,

Pharmaceutical Chemist.

In investigating the action of various solvents, oxidizing agents, etc., upon the active principles of the fruit of the official capsicum, and of the rhizome of *Zingiberis officinalis*, I have become so convinced, from the many properties they possess in common, that they belong to a well-defined and hitherto unexamined group of proximate principles, that as leisure permits I purpose continuing their examination, and to ascertain whether other vegetable substances of a pungent character contain the same or similar principles I am now examining a number of such drugs. In some cases these have previously been only very imperfectly examined; they are therefore being submitted to proximate analysis with the view of placing the results obtained on record. As yet the examination of the so-called "grains of paradise" has alone progressed sufficiently far to form the basis of a communication to this Society. I may add, however, that I have succeeded in isolating the active principles of this drug and also of the rhizome of *Alpinia officinarum* (Hance) the "galangal" of commerce, and the very imperfect examination to which I could submit the small quantities obtained was sufficient to prove that whilst not identical with either of the principles previously mentioned and differing from each other yet that both unmistakably belonged to the same class of bodies.

Grains of paradise appear to have been analysed in 1811 by Willert, who found volatile oil, ·52; acrid resin, 3·40; extractive, 1·27; tragacanthin and woody fibre, 82·8; water and loss, 12·01 per cent. respectively Later, Sandrock found in the alcoholic extract two resins, one precipitable by neutral lead acetate, and the other not. The volatile oil, however, is the only constituent which can be said to have been examined and the result obtained by Flückiger will be found

* Read at an Evening Meeting of the Pharmaceutical Society, April 2, 1884.

in the 'Pharmacographia,' and need not be transcribed. Flückiger also exhausted 10 grams of the seed with boiling ether and obtained "·583 gram of a brown viscid residue, almost devoid of odour, but of intense pungency." This residue was soluble in glacial acetic acid and spirit of wine.

The information thus available was too meagre to permit of any deduction as to the best mode of procedure in conducting a proximate analysis, and the following preliminary experiments were therefore made.

Ten grams of the seed in fine powder were exhausted with ether (ether, B.P.). The extractive obtained weighed ·571 gram. It proved to be incompletely soluble in petroleum ether; the insoluble portion contained both resinous and astringent matter (striking a blue-black colour with ferroso-ferric salts), but was entirely soluble in spirit of wine.

Two grams of the seed were then exhausted with boiling 95 per cent. alcohol and upon evaporation ·140 gram or 7 per cent. of a soft, dark red-brown pungent residue was obtained, only partially soluble in ether.

By exhaustion with 70 per cent. alcohol 10 grams yielded (after deducting ash) ·66 gram of extractive, of which ·13 dissolved in water.

We have therefore—

Substances extracted by ether, 5·71 per cent.

Substances extracted by 95 per cent. alcohol, 7 per cent.

Substances extracted by 70 per cent. alcohol, 6·6 per cent.

I concluded from the results thus obtained that it would be best to exhaust successively with petroleum ether, dry ether, and 95 per cent. alcohol, before treating with water, etc. I am now, however, of opinion that it would have been better to have omitted the percolation with ether, as the solution so obtained was entirely soluble in alcohol and contained a considerable proportion of the astringent matter which I had hoped would have been left in the marc and afterwards taken up by the alcohol. It is an open question as to whether the tannins are absolutely insoluble in dry ether, but apparently in presence of resinous matter ether may take up no inconsiderable quantity.

For the proximate analysis of the seeds a quantity was carefully picked over and reduced to an exceedingly fine powder, by repeated grinding and careful sifting.

*Exhaustion with Petroleum Ether.** — 20 grams were placed in a flask with 100 c.c. of the petroleum and boiled for some hours, then transferred to a percolator and continuous percolation with the boiling menstruum continued for twenty-four hours. Two lots of ether were employed and as the latter was only very faintly tinted after several hours' percolation, exhaustion was deemed complete. During the ebullition a small quantity of pale yellow semi-fluid matter was deposited and from this after cooling the supernatant fluid was poured off. One-twentieth (5 c.c.) of the solution was placed in a small flask and a current of dry coal gas passed through the flask until a constant weight was attained. The flask was next kept at 100° C. until the loss of weight after fifteen minutes' further exposure was trifling. The loss is set down as essential oil, but the result is probably a little too high, for the active principle, a portion of which is present in this solution, is slowly decomposed at this temperature with continuous diminution in weight. Thus were obtained—

Volatile oil, ·63 per cent.

Total petroleum extractive, 5·09 per cent.

Volatile Oil.—My observations simply confirm those of Flückiger previously referred to.

Active Principle. — I purposely refrain from giving this substances a name until my examination of it is more advanced. Both the semi-fluid portion deposited by the petroleum and the petroleum solution were very pungent; they were, therefore, mixed and the ether distilled off. The pale yellow oily fluid upon standing deposited a very small quantity of indistinctly crystalline matter. The whole of this residue was shaken with equal quantities of petroleum ether and 70 per cent. alcohol when it entirely dissolved. The alcoholic solution, which from its pungency evidently contained nearly the whole of the active principle, was agitated with a fresh quantity of petroleum ether, and then precipitated with basic lead acetate. The bright yellow precipitate produced adhered to the side of the containing vessel and was removed by agitation with a little silica and filtration. The filtrate after treatment with H_2S was evaporated in a partial vacuum (b. h. about 360 mm.) until all or nearly all the alcohol was removed, and the residue agitated with chloroform. The chloroform solution deposits upon evaporation the active principle. It is a straw coloured, viscid, odourless fluid, pungent in taste (not nearly so hot as capsaicin, but probably hotter than the pungent principle of ginger). It is slightly soluble in petroleum ether and petroleum, very soluble even in dilute alcohol, also in benzol, chloroform, ether, carbon disulphide, glacial acetic acid and solution of potash. From the latter solution it is precipitated by CO_2 and by ammonium chloride. The KHO solution gives with $BaCl_2$, $CaCl_2$, $Mg(C_2H_3O_2)_2$ and $Zn(C_2H_3O_2)_2$, very voluminous pale yellow precipitates soluble in alcohol. Copper acetate gives a green precipitate which upon heating adheres to side of tube. It is very readily oxidized. Warm chromic acid mixture acts energetically upon it with copious evolution of carbonic acid gas and formation of two or more acids of the $C_nH_{2n}O_2$ series. Strong sulphuric acid dissolves it and if care is taken to prevent rise of temperature (which otherwise is considerable and causes carbonization and evolution of SO_2) a dark red solution is obtainable, which if poured into a large quantity of cold water yields a slightly opalescent nearly colourless solution. It readily reduces an ammoniacal solution of silver nitrate with production of a metallic mirror. Hot dilute nitric acid oxidizes it, yielding a reddish resinous mass, which by the action of solvents is found to be a mixture of two or more substances; also carbonic acid, an oily acid with odour of caproic acid, oxalic and succinic acids. Strong nitric acid acts energetically upon it, yielding a pale yellow solution miscible with water. On evaporation a crystalline residue is obtained consisting chiefly of oxalic acid together with succinic. The action of fused potash, of reducing agents, etc., has also been tried, but the results obtained need confirmation by experiment upon larger quantities of material, and are reserved for a future communication.

* The petroleum ether employed in these investigations was portion of a large fraction which came over between 40° and 44° C. upon distilling a light gas oil.

Resin Precipitated by Lead Acetate from the Alcoholic Solution.—The lead salt was decomposed by H_2S and the solution evaporated. The soft, reddish-brown resinous residue had a pungent taste. It appeared to be a mixture of the active principle and a resin. It dissolved in dilute alcohol, the solution, if not too dilute, precipitating with neutral lead acetate. With basic lead acetate it gave a copious yellow precipitate, the lead salt not passing into solution when shaken with petroleum ether. This resinous matter corresponded to about ·5 per cent. of the seed.

The petroleum solution was distilled to remove the ether and the residue dissolved in a little glacial acetic acid. Upon adding a few drops of water and warming, the essential oil separated and floated on the acid. The latter upon cooling became almost solid from deposition of what appeared to be a granular fat. This was removed, and the following properties noted. Melting point (about) 80° F.; upon cooling it had an indistinctly crystalline, pale brown, fatty appearance; very readily soluble in ether, petroleum ether, carbon disulphide, chloroform, benzol, acetic acid and rectified spirit. It has a slightly acid reaction and dissolved in warm 50 per cent. alcohol, in hot solution of sodium carbonate and in solution of potash; in the two latter cases with production of an orange colour. With neutral lead acetate it yields a white precipitate, with the basic acetate a yellow precipitate, which dissolves instantly when shaken with petroleum ether to an orange solution. Upon evaporation this leaves a bright yellow varnish-like residue.

This principle, which I hope to further examine, constitutes about ·80 per cent. of the seeds.

Extraction with Dry Ether.—The percolator containing the marc exhausted with petroleum ether was attached to a filter pump and a current of dry air drawn through to remove the petroleum still remaining in the residue. Ether (specific gravity ·717) was then poured on and after two days' digestion continuous percolation with boiling ether was conducted for about eight hours. The pale yellow solution thus obtained was partially distilled, the remainder of the ether driven off in a current of air at a low temperature, and then exposed for a few minutes to the heat of a water-bath.

The residue corresponded to 1·42 per cent. of the original seed, and was resinous, soft, slightly pungent, pale brownish-yellow and odourless. Treated with carbon disulphide or petroleum ether, a very small portion only was dissolved and this proved to be in the latter case a trace of the active principle which had escaped the previous action of this solvent. It was entirely soluble in rectified spirit, and the solution precipitated copiously with neutral lead acetate. The precipitate was collected, decomposed by H_2S, the solution (alcoholic) evaporated and the residue weighed. It corresponded to ·56 per cent. of the drug. It undoubtedly consisted of a tannin associated with a little resinous matter, difficult to separate. It was amorphous, hard, brittle, red-brown and formed with water an opalescent solution. Soluble in dilute alcohol, and in ether, B.P., but almost unaffected by pure ether, benzol, carbon disulphide and chloroform. Ammonia did not readily dissolve it, but with potash it yielded a rich red solution, and partial precipitation ensued upon addition of ammonium chloride to this solution. In aqueous solution ferroso-ferric salts struck a blue black colour, barium hydrate gave a blue precipitate, silver nitrate and ammonia a black precipitate instantly. It precipitated gelatine solution, and solution of cinchonine salts and reduced Fehling's solution. All attempts to obtain any crystalline bodies by treatment with ether, acetic ether, etc., and careful evaporation were unavailing.

The portion of the ethereal extract insoluble in boiling petroleum ether and not precipitated by lead acetate was devoid of pungency and consisted of resinous matter with probably some decomposition products of the tannin. By action of benzol it could be divided into two portions, the one soluble, the other insoluble therein. Both were unaffected by water, but soluble in solution of the fixed akalies and in glacial acetic acid and in chloroform. The former also dissolved in solution of ammonia and in carbon disulphide; the latter was unaffected by both.

Exhaustion with 84 *per cent. Alcohol.*—The percolator containing the marc from the ether treatment was again attached to the filter pump, and after removal of the ether, rectified spirit was passed through to exhaustion. 100 c.c. of a pale yellowish tincture were thus collected. 20 c.c. upon evaporation to dryness left a residue weighing ·040 gram, and upon ignition this yielded ·003 gram ash. The combustible matter, therefore, taken up by the spirit represents ·93 per cent. of the seeds employed. The red-brown brittle residue left on distilling off the spirit under diminished pressure had a faintly astringent taste. The portion soluble in water was estimated, and in its properties found to coincide closely, but not entirely, with the astringent matter found in the ethereal extract. It only precipitated gelatine distinctly after addition of common salt, and it did not give instantly a black precipitate with ammoniacal solution of silver nitrate, but it rapidly reduced it when heated therewith. I am inclined to think there are two distinct astringent tannin-like bodies present in the seeds, but it is not improbable that the differences observed may be due to impurities associated therewith.

The portion of the alcoholic extract not dissolved in water was almost completely soluble in very dilute ammonia, yielding a red-brown solution. When heated it did not melt, but gave off a disagreeable odour and burnt with a luminous flame, leaving a voluminous char. The precipitate produced by addition of an acid to the alkaline solution, when dry was almost black, and not completely soluble in rectified spirit. Quantitative estimations of an aliquot part of the alcoholic extract gave the following results:—

Astringent matter	·43 per cent.
Phlobophane	·50 ,,
Matter insoluble in water, ammonia and spirit	·07 ,,

Exhaustion with Cold Water.—The marc left after exhaustion by petroleum ether, ether and alcohol was now transferred to a beaker and dried at a low temperature. 200 c.c. of water were then added and the mixture stirred from time to time for two days. The liquid was neutral, colourless, tasteless, and though limpid it filtered very slowly. 10 c.c. of the filtrate yielded ·0225 gram of dry residue, containing ·0035 gram ash.

The mucilage was determined in the usual manner, and after removal of the alcohol in the filtrate from mucilage precipitate the organic acids present were precipitated by lead acetate and estimated by ignition of the precipitate. The aqueous solution did not reduce Fehling's solution until after ebullition with acids, but appeared to contain an appreciable amount of nitrogenous matter.

The aqueous infusion when evaporated on the water-bath deposited flocks of nitrogenous matter which refused to redissolve in water. Mixed with one-fourth its volume of a saturated solution of salt it at once became turbid and slowly deposited a white flocculent matter. Addition of more salt, of acid or of water again dissolved it. The infusion was also coloured brown by iodine, and precipitated with ferrocyanide of potassium and acetic acids.

The total aqueous extract (— ash) was made up of—

Mucilage	·22	per cent.
Organic acid, etc., precipitated by lead acetate	·38	„
Albumenoid	1·3	„
Total	1·9	„

From the difficulty in effecting filtration of the infusion and the fact that it frothed readily and precipitated copiously with barium hydrate, a special search for saponin or an allied body was conducted, but with negative results.

Exhaustion with ·2 per cent. Caustic Soda Solution.—After decanting and filtering the aqueous infusion the residue was digested in ·2 per cent. solution of caustic soda for twenty-four hours. The solution thus obtained filtered easily, and a portion was precipitated with acetic acid and alcohol and the metarabin and ash estimated. Upon evaporating the filtrate the residue was found to weigh less than the sodium acetate which should have been present. Titration of a portion of the alkaline solution proved that about two thirds of the caustic soda used had been taken up by the insoluble vegetable matter.

Estimation of Starch.—The residue which had been treated with dilute alkali was boiled with 200 c.c. of water, and digested with a little fresh diastase in the usual manner, and when the action was completed an aliquot portion was filtered off, acidulated with hydrochloric acid, boiled for four hours and the sugar finally determined with Fehling's solution. The glucose found corresponded to 27·3 per cent. of starch in the original seed.

Pararabin.—After removal of the starch the residue was boiled with 1 per cent. hydrochloric acid and in the filtrate the pararabin estimated. It corresponded to 3·12 per cent. of the seed employed.

The acid solution was dark brown in colour and much more of the constituents of the seed had been dissolved (probably only after decomposition) than was afterwards precipitated by alkalies.

Cellulose.—The residue from the above treatment was finally digested with warm dilute nitric acid (sp. gr. 1·18), to which a little potassium chlorate was added, and the colourless insoluble portion collected on a filter and washed successively with water, dilute ammonia, and alcohol, dried and weighed. The amount of cellulose thus obtained was 1·13 gram.

Moisture and Ash.—Two determinations of the moisture were made by exposing the finely ground seeds in a hot air oven to a temp. of 110° C., until there was no further loss of weight.

1·292 grams lost	·333 or 16·7	per cent.
2·195 grams lost	·368 or 16·8	per cent.

deducting ·6 per cent. for volatile oil, we have as mean of both experiments—

Moisture . . . . 16·15 per cent.

The ash was determined by burning the portion first dried in a platinum crucible in a kind of muffle. The ash was of a pale brown colour, and weighed, ·0668 gram corresponding to 3·36 per cent. of the undried seed.

My assistant (Mr. Thornton) examined the ash from a larger quantity of seed and obtained the following results:—

Ash soluble in water	·60 per cent.
Ash soluble in acid	1·30 per cent.

The remainder (1·44 per cent.) consisted chiefly of sand.

The soluble ash was only faintly alkaline and did not efferverse perceptibly with acids. It consisted almost entirely of potassium and sodium sulphates.

The portion soluble in hydrochloric acid consisted of the phosphates of calcium and aluminium and magnesium, with large traces of manganese and iron.

Albumenoids.—The nitrogen in 1·487 gram of the seed was determined by the method of Will and Varrentrap. The platinum obtained weighed ·0905 gram, corresponding to ·86 per cent. of nitrogen in the undried seed. This may be regarded as equivalent to 5·4 per cent. of albumenoids.

Tabulated Results of the Analysis.

Soluble in Petroleum Ether.	Volatile oil	·63
	Active principle	3·39
	Resin	·50
	(?) Acid	·80
Soluble in Alcohol.	Tannin	·99
	Phlobophane	·50
	Resins	·63
Soluble in Cold Water.	Mucilage	·22
	Organic acids, etc., precipitated by lead acetate	·38
	Albuminoid	1·30
Taken up by successive treatment with dilute alkali; boiling water and dilute acids.	Metarabin	·79
	Starch	27·30

Ash		3·36
Moisture		16·05
		100·00

SAPONIN FROM SAPONARIA OFFICINALIS.*

BY C. SCHIAPARELLI.

The analyses hitherto made of saponin obtained from different plants are not very concordant, the results varying indeed from 47·52 per cent. C. and 7·16 H. (Overbeck) to 52·63 C. and 7·48 H. (Rochleder and Schwarz). Moreover the experiments of the last-named chemist lead to the conclusion that the carbohydrate obtained in the first instance from saponin by decomposition with acids, is not grape-sugar, but a body convertible into that sugar by the further action of acids,—and consequently that saponin is not a glucoside but an amyloid. To throw further light on this matter, the author has endeavoured to determine whether the products extracted from different plants and included under the name of saponin, are really identical, and in the present paper he describes the results obtained with saponin from *Saponaria officinalis*.

The root of this plant, dried and coarsely pounded,

* From *Gazzetta*, xiii., 422–430. Reprinted from the *Journal of the Chemical Society*.

was boiled for three days in a reflux apparatus with alcohol of 90°; after which the boiling alcoholic decoction was separated and left for some days in a cool place, whereupon the sides of the vessel became coated with a copious yellow flocculent deposit which, when freed from colouring matter by treatment with a warm mixture of alcohol and ether, consisted of saponin, still, however, very impure. Treatment with alcohol and animal charcoal still left it contaminated with about 3 per cent. of mineral matter. It was, therefore dissolved in the smallest possible quantity of water; the cold solution was precipitated with saturated baryta-water; the resulting barium saponate, after washing with baryta-water, was suspended in water and decomposed by a current of carbonic anhydride, then heated to the boiling point, and filtered; the filtrate evaporated to a syrup at a gentle heat was precipitated with alcohol; and the still yellowish saponin was further purified with alcohol of 90 per cent. The substance thus obtained still contained barium salts, to remove which it was dissolved in water and treated with dilute sulphuric acid, added drop by drop; and the filtered liquid, after concentration at a gentle heat, was precipitated with alcohol and ether, these operations being repeated a second and a third time, and the product finally purified with boiling alcohol of 90 per cent. in quantity not sufficient to dissolve it completely. The alcoholic solution evaporated in a vacuum left perfectly white flocks of pure saponin, which were washed with ether and dried over sulphuric acid.

Saponin thus prepared gave, as the mean result of five analyses, 52·65 per cent. carbon and 7·36 hydrogen, agreeing nearly with the formula $C_{32}H_{54}O_{18}$, which requires 52·86 C. and 7·44 H. Saponin from *Gypsophila* was found by Rochleder to contain 52·65 carbon and 7·34 hydrogen.

Pure saponin is a very white amorphous inodorous powder, which excites sneezing when inhaled by the nostrils; it has a pungent disagreeable taste, and is poisonous; dissolves very freely in water, but is insoluble in ether, benzene, and chloroform, and only slightly soluble in alcohol. Heated on platinum foil, it decomposes, emitting an odour of burnt sugar, and leaving a porous residue difficult to burn. Saponin is lævogyrate, like most glucosides; specific rotatory power $[\alpha]_D = -7·30$: it is the least optically active of all known glucosides.

Saponin, as already observed, is remarkable for the power of its aqueous solution to dissolve salts which are insoluble in water. When its aqueous solution, mixed with lead acetate, is precipitated by hydrogen sulphide and filtered the liquid which passes through is black from dissolved lead sulphide, which may be precipitated from it by adding a small quantity of alcohol. A boiling aqueous solution of saponin dissolves barium carbonate (up to 10 per cent.), which may be precipitated by sulphuric acid; nevertheless barium sulphate is slightly soluble in aqueous saponin. This property of dissolving salts throws great difficulty, as already observed, in the way of purifying saponin. This substance likewise dissolves gases and incloses them mechanically. A dilute aqueous solution of saponin forms on agitation a very persistent froth.

An aqueous solution of saponin mixed with hydroxide of potassium, barium, or strontium, yields precipitates of the corresponding compounds. The barium compound has the composition—

$$C_{32}H_{53}O_{18}.BaC_{32}H_{52}O_{18}.BaC_{32}H_{53}O_{18}.$$

Products of Decomposition of Saponin.—An aqueous solution of saponin was heated on a water-bath with dilute sulphuric or hydrochloric acid, the liquid being filtered after two hours, in order to remove the flocculent substance which separated, and thereby prevent its further decomposition by the acid; the filtered solution was then again boiled, the new precipitate separated, and these operations were repeated a third time. The three precipitates thus obtained agreed very closely in composition, giving as the mean result of their analysis, 60·65 per cent. carbon and 8·22 hydrogen, numbers agreeing nearly with the formula $C_{40}H_{66}O_{18}$, which requires 61·06 carbon, 8·38 hydrogen, and 3·56 oxygen. The decomposition of saponin by dilute acids may therefore be represented by the equation—

$$2\,C_{32}H_{54}O_{18} + 3\,H_2O = C_{40}H_{66}O_{15} + 4\,C_6H_{12}O_6.$$

The compound $C_{40}H_{66}O_{15}$ is called by the author saponetin, to distinguish it from the *sapogenin* of Rochleder and others, which was not of constant composition. Saponetin is a whitish microcrystalline substance, insoluble in water, alcohol, and ether.

The glucose formed by the action of dilute acids on saponin is dextrogyrate, its specific rotatory power being $[\alpha]_D = +52·48$. It is fermentable, has a saccharine taste, and has not yet been crystallized, its solution, after concentration to a syrup, having remained for six months without giving any sign of crystallization. Further experiments are, however, required to determine whether it is a peculiar sugar distinct from dextrose, or whether the difference between its optical rotatory power and that of the latter is due to some other cause.

HYDROCYANIDES OF ORGANIC BASES.*

BY A. CLAUS AND E. A. MERCK.

Aniline, toluidine, quinine, cinchonidine, and strychnine, dissolve in aqueous hydrocyanic acid. An excess of acid renders the solution very unstable. The salts have not been isolated, as they are decomposed by evaporation in a vacuum. Although the bases are completely withdrawn from these liquids by ether, the solutions are not mere mechanical mixtures, since they yield double cyanides with mercuric cyanide; *e.g.*, when mercuric cyanide is added to a solution of aniline hydrocyanide, white tabular crystals, $NH_2Ph,HCN + Hg(CN)_2$, are deposited, which dissolve in water, alcohol, and ether.

When mercuric cyanide is added to tetramethylammonium iodide, two salts are formed, viz., a white salt of the composition $NMe_4I,Hg(CN)_2$, freely soluble in water, and a yellow salt, $NMe_4.CN,HgICN$, sparingly soluble in water. The white salt slowly changes into the yellow isomeride at the ordinary temperature, more rapidly at 200°.

Tetramethylammonium cyanide, $NMe_4.CN$, prepared by the action of barium cyanide on tetramethylammonium iodide, has been described by C. Thompson. The clear crystals of the salt become opaque at 150°, decrepitate at 215°, and melt at 295°. The salt can be volatilized at 225–230° without melting. With mercuric cyanide it forms a double salt, $NMe_4.CN,Hg(CN)_2$, crystallizing in prisms melting at 275°. The corresponding silver salt, $NMe_4.CN,AgCN$, has been described by Thompson. Tetramethylammonium cyanide dissolves cobalt cyanide and ferrous cyanide, forming tetramethylammonium cobalticyanine and ferrocyanide respectively. The latter compound has been described by Barth (*Ber.*, viii., 1484). The former crystallizes in yellow plates, and resembles the potassium cobalticyanide in its properties.

Cinchonidine ethylcyanide, $C_{19}H_{22}N_2O,EtCN$, prepared by the action of barium cyanide on cinchonidine ethylsulphate, forms white crystalline needles, which are decomposed by carbonic acid, and rapidly absorb moisture from the air. It is soluble in water but insoluble in ether and chloroform. The crystals melt with decomposition at 140°. *Quinine ethylcyanide*, $C_{20}H_{24}N_2O_2,EtCN$, crystallizes in needles soluble in alcohol. The crystals melt at 90° and begin to decompose at 95°. *Strychnine ethylcyanide*, $C_{21}H_{22}N_2O_2,EtCN$, is less hygroscopic and more stable than the quinine and cinchonidine compounds. It dissolves freely in water, but is less soluble in alcohol.

The Pharmaceutical Journal.

SATURDAY, APRIL 5, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACISTS AND THE PHARMACOPŒIA COMMITTEE.

The announcement made in a recent number of this Journal that the Medical Acts Amendment Bill, as reintroduced by the Government into the House of Lords, contained the previous provisions as to the preparation of future editions of the British Pharmacopœia in an unaltered form, will have prepared our readers for the tone of some correspondence with the Privy Council department which was submitted to the Council of the Pharmaceutical Society at its meeting on Wednesday last, and is printed on page 809. It was hardly to be hoped that the omission of the Government to respond to the reasonable request of the pharmacists of Great Britain and Ireland that provision should be made to give them a proper position in future pharmacopœia committees, backed as it was by the presentation to the House of Commons last August of upwards of two hundred and fifty petitions, bearing more than four thousand signatures, could have been the result of oversight or inadvertence. Nevertheless, as the Lord President of the Council had intimated in his place in the House of Lords that it was his intention to move some amendments whilst the Bill was in Committee, the President of the Pharmaceutical Society took the opportunity of inquiring by letter whether it was intended to include among those amendments one providing for the formation of a Pharmacopœia Committee including pharmaceutical chemists as well as medical practitioners. The reply was simply an expression of regret that the Lord President did not see his way to amend the Medical Acts Amendment Bill in the manner suggested.

This reply evidently left to the Pharmaceutical Council the alternative of retreating from the position it has taken up in respect to this question, or of making an attempt to impress its views upon Parliament more effectively than it had upon Her Majesty's ministers. As to which course the Council would decide to adopt there could be little doubt, and we believe that the members of the Society will, almost without exception, approve of the instruction given to the Law and Parliamentary Committee to take such steps as it may deem advisable to secure the amendment of the Bill in the direction desired before it passes into law The particular steps that will be found desirable are as yet uncertain and will require most careful consideration; but meanwhile the field in which they can be taken has become more circumscribed, since during the past few days the Bill has been pushed through its remaining stages in the House of Lords and on Thursday it was read a third time and sent down to the House of Commons. Probably its first reading in that assembly will take place early next week; but in the present state of public business the succeeding stages are very uncertain. We presume, however, that an effort will be made to ensure that on the occasion of the second reading the case of pharmacists shall, in some way, be laid before the House of Commons, but presumably the principal effort will have to be made when the Bill is in Committee. It will, therefore, almost certainly become necessary to call upon the local secretaries and other friends to repeat the good work done last year in securing the filling up of petitions from their respective localities and arranging for their presentation when they receive an intimation that the proper time has arrived. Meanwhile every opportunity should be taken by all chemists and druggists to lay before any members of Parliament whom they may be able to approach a clear statement of the nature of the amendment which it is proposed to effect in the Bill, and to point out that the privilege for which British and Irish pharmacists are asking is one already possessed by the corresponding class in almost every other civilized country and has everywhere been acknowledged by the medical profession to be of material benefit. If the question were once properly comprehended by the members of the Legislature there would hardly be a doubt as to the result; whilst, on the other hand, the dread of interfering without the requisite special knowledge in a technical dispute may induce many to follow blindly what might appear to them authoritative guidance. In the words of Mr. Hampson, what is wanted is not so much to exercise pressure upon the Government, as to show the House of Commons that this claim put forward by pharmacists and supported by many medical practitioners is a just and reasonable one. Very few of our readers need now to be informed as to the conditions under which the most important national pharmacopœias other than our own are prepared; but in the event of anyone wishing to refresh his memory as to the facts, he will find them epitomized in an article that appeared in this Journal exactly a year ago. It would, however, seem to be worthy the consideration of the Law and Parliamentary Committee whether it might not be advisable to draw up and issue, in a pamphlet form, a brief statement, suitable for conveying information on the chief features of the subject succinctly to the minds of members of the Legislature and others whom it may be desired to interest.

In conclusion, reference may be made to the fact that at the sitting of the Medical Council on the 27th ult., a report was presented from the Pharmacopœia Committee as to its proceedings since April in last year. From this we learn that "the "arrangements for the preparation of the next "edition of the Pharmacopœia have been continuous; "the Sub-Committee has met on four occasions and "has been in communication with the editors per-"sonally and by written reports." Mention is made of a "memorandum" that has been issued to various medical authorities, pharmaceutical bodies and gentlemen holding prominent positions as practical pharmacists and manufacturing chemists, and it is stated that in reply many valuable suggestions have been received for which the thanks of the Medical Council are due. The pharmacists and manufacturing chemists mentioned by name as having afforded valuable information for which the Committee is very much indebted are Messrs. J. B. Barnes, London; W. Inglis Clark, D.Sc., for Duncan, Flockhart and Co., Edinburgh; S. Gale, for John Bell and Co., London; D. Howard, for Howard and Sons, Stratford; F. J. Macfarlane and Co., Edinburgh; B. S. Proctor, Newcastle; J. C. Thresh, D.Sc., Buxton; Thomas Farries, for Burgoyne, Burbidges, Cyriax and Farries, London; John Moss, for Stagg, Harker and Moss, London; F. W. Fletcher, Edinburgh; and T. and H. Smith and Co., Edinburgh. Many of the suggestions made are said to have been previously anticipated, but all the communications have been handed over to the "skilled editors" for their consideration, and the Committee expresses itself satisfied that the information already in their hands will be sufficient to render the next edition of the British Pharmacopœia worthy of the approval of the Council and the profession. This statement seems to suggest that a considerable advance has been made in the preparation of the new work, and is in accordance with a rumour that it will make its appearance in the early part of next autumn.

EXAMINATION STATISTICS.

The proportion of candidates who fail to pass the examinations under the Pharmacy Act will naturally always be scanned with interest, lest an undue degree of stringency may involve a corresponding amount of hardship. Especially is this interest apt to acquire a tinge of uneasiness when, as is sometimes the case, the proportion of rejections attains a very high figure. It is therefore useful, when opportunity occurs, to note the "pass and pluck" statistics of other bodies, in order to see how far the experience is common to different examinations. Such an opportunity is afforded by the publication of some statistics presented to the Medical Council during its recent session. First in order, as dealing with the earliest stage, may be mentioned a communication from the College of Preceptors, giving the results of the Preliminary examination for medical students and others, under its superintendence, in September last. From this we learn that out of 264 candidates who were examined in London and other centres only 82, or rather less than one-third, succeeded in obtaining certificates qualifying for registration as medical students. Of the remainder, 20 passed in all the obligatory subjects, but failed to obtain the minimum number of marks to entitle them to be placed in the second division of the second class, as required by the regulations of the Medical Council. As to those who were unsuccessful in obligatory subjects, 61 failed in one, 25 in two, 26 in three, and 38 in four or more. Thirty-two candidates were reported for defective spelling, and one was disqualified on that account alone. This proportion of failures, it is needless to say, is considerably larger than the average of failures among candidates in the pharmaceutical Preliminary examination.

Advancing to the next stage, we may refer to a return which was presented showing the percentage of successful and unsuccessful candidates amongst all who presented themselves at the different medical examining boards in the three kingdoms during the year 1883. From this document it appears that the total number of candidates who presented themselves at the first professional examinations was 4171, of whom 2579, or 62 per cent., passed, and 1592 were rejected. In the second examinations the proportion of passes was a little higher, for out of 1239 candidates 815, or nearly 66 per cent. were successful. The third examinations showed still more decided indications as to the quality of the class that had been previously eliminated, for in these the proportion of successful candidates rose to 71 per cent., the number being 2700 out of 3802. As compared with the average results attending the Minor pharmaceutical examination the proportion of passes in each of these medical examinations, taken individually, seems to be more favourable; but if it be remembered that in the latter case the single Minor examination is all that a candidate has to pass, after the Preliminary examination, to entitle him to registration as a fully qualified chemist and druggist it will be seen that the discrepancy is more apparent than real.

Another point which has occasionally been the subject of discussion among pharmacists was illustrated by some volunteer statistics presented to the Medical Council by Dr. Aquilla Smith, showing the relation which the proportions of candidates successful in the examinations of the present day bear to those which obtained in former years. Some of these figures are rather remarkable, since they show that medical examining boards, in some instances, last year rejected two and three times as many candidates in proportion to those who passed as in the year 1867. It is true that, in some instances, it might be objected that possibly passing events may be exercising more or less temporary influence on the stringency of the examinations but it is somewhat striking to find that last year the percentage of rejections by the Royal College of Physicians, London, was 20 per cent., against 11·2; and the percentage of rejections by the Royal College of Surgeons, England, 36·7 per cent. in 1883, against 12 per cent. in 1867. Although probably to produce this result several distinct causes have contributed, important amongst which it may be assumed stand the wider demands of the examiners in view of the enormous strides taken by science in the last quarter of a century, the force of Dr. AQUILLA SMITH'S remark must be admitted when he says that the large proportion of candidates rejected by the College of Preceptors, considered in conjunction with the large proportion of failures in the primary professional examinations, furnishes unmistakable evidence that there is a great defect in the primary education of young men of the class that seek to enter the medical profession.

The goodly list of Stewards published on another page, numbering about one hundred and fifty names, is a promising indication that on the occasion of the Annual Dinner of the Members of the Pharmaceutical Society and their friends, on the 20th of next month, the President will have the support of a large number of leading pharmacists. This is as it should be, for although these *réunions* were primarily initiated with a view of facilitating social intercourse between the members of the Society resident in London and those who come up from the country to attend the annual meetings, they furnish admirable opportunities for demonstrating the practical unity of the body of pharmacists at important crises like the present. We would recommend in order to promote those arrangements that are so essential to the general comfort at such gatherings that persons intending to be present should make an early application for tickets to the Honorary Secretary, Mr. Richard Bremridge.

* * *

In the House of Commons, in reply to a question put by Mr. Warton, on Thursday, Mr. Mundella stated that the Government Bill relating to the sale of poisons will be introduced in the House of Lords after Easter.

* * *

A report that will be found on another page incidentally illustrates the position which no inconsiderable number of chemists and druggists take towards every attempt at the organization and improvement of the body to which they belong. A Mr. Gibson, carrying on business as a chemist and druggist in Southampton, having in the course of evidence given at an inquest stated that he was a registered chemist and druggist, the coroner, having consulted the Register without finding a corresponding entry, called his attention to the fact, when Mr. Gibson offered the explanation that he was registered as living at Middlesborough-on-Tees. Upon the coroner asking him, very pertinently, whether he did not consider it his duty to see that his address in the Register was corrected now that he was residing in Southampton, he is reported to have replied that "that was for the Local Secretary who assisted in compiling the book to see to." Why Mr. Gibson should assume that it is the business of an honorary official of a Society from which he has hitherto held aloof to attend to business that concerns himself alone, we are unable to understand, though we prefer to attribute it to some misapprehension. However this may be, it is certain that if his neglect to keep the Registrar under the Pharmacy Act informed as to any changes of residence he may make results at some time in his name being struck off the Register, he will have himself only to thank for any inconvenience that may follow. Since a question is said to be frequently raised as to what the Pharmaceutical Society does for the trade, we may mention, as a contribution towards answering it, that a few days ago upwards of seven hundred registered letters were sent out, at the Society's expense, to persons whose place of residence was suspected to be no longer represented by the entry in the official Register, and that the greater number of these have already been returned through the Dead Letter Office.

* * *

A paragraph in the current number of the *Journal de Pharmacie* calls attention to the fact that the poisonous variety of star anise derived from *Illicium religiosum*, Sieb., has been detected in the stock of a herbalist in Paris, and that its use is known to have already been followed by serious consequences in two cases at least in that city. As, therefore, it would appear that parcels of this dangerous drug are still met with in commerce, it may be useful to remind our readers that the "star anise" from different species of *Illicium* have been described and figured in an article by Mr. E. M. Holmes, which appeared in the number of this Journal for December 18, 1880.

* * *

In connection with the International Health Exhibition arrangements have been made for the establishment of a library and reading room, which are to be located in a large double room in the Albert Hall, overlooking the Conservatory. It is intended that the library shall contain a representative collection of literature on vital statistics and public health, and that the reading room shall be supplied with the current numbers of periodical publications of a sanitary or educational character. Foreign powers and the Indian and Colonial Governments have been invited to assist in making this department of the exhibition as complete as possible and a general request is made to authors and publishers to contribute copies of works treating of cognate subjects.

* * *

A meeting of the London Section of the Society of Chemical Industry will be held on Monday evening next, at 8 p.m., in the Chemical Society's rooms, Burlington House. The first business will be the election of the Local Committee. Afterwards, papers will be read on "Certain Bye-Products of the Pintsch Oil-Gas Manufacture, in Relation to the Conditions under which Benzenes are formed," by Dr. Armstrong; "The Estimation of Sulphurous Acid in its Compounds," by Messrs. Giles and Shearer; and "The Solidification of Liquid Oils," by Mr. W. J. Carpenter.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, April 9, at 9 p.m. precisely, when a paper on "Operative Dentistry" will be read by Dr. Albert J. Kutz.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, April 2, 1884.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Symes, Williams, and Young.

The minutes of the previous meeting were read and confirmed.

Nominations for Council and Auditors.

Council.

The Secretary reported that he had received *twenty* nominations to fill the *fourteen* vacant seats on the Council and that the following *eighteen* had declared their willingness to accept office if elected:—

Atkins, Samuel Ralph, Market Place, Salisbury.
Baldock, John Henry, 3, High Street, South Norwood, S.E.
Borland, John, 7, King Street, Kilmarnock.
Butt, Edward Northway, 13, Curzon Street, Mayfair, W.
Churchill, Walter John, 46, New Street, Birmingham.
Dyer, William, 1 Corn Market, Halifax.
Gostling, Thomas Preston, Market Hill, Diss.
Greenish, Thomas, 20, New Street, Dorset Square, N.W.
Radley, William Valentine, 42, Hampton Road, Southport.
Robbins, John, 147, Oxford Street, W.
Savage, William Dawson, 4, Park Road East, Brighton.
Schacht, Geo. F., 52, Royal York Crescent, Clifton, Bristol.
Shapley, Charles, 11, Strand, Torquay.
Squire, Peter Wyatt, 413, Oxford Street, W,
Williams, John, 16, Cross Street, Hatton Garden, E.C.
Woolley, George Stephen, 69, Market Steeet, Manchester.
Young, James Robertson, 17, North Bridge, Edinburgh.
Young, John Rymer, 42, Sankey Street, Warrington, Lancs.

The following *two* had declined to accept office:—

Allen, Charles Bowen, 3, Manchester Ter., Kilburn, N.W.
Pickering, Atkinson, 45, Lowgate, Hull.

Auditors.

The following had been nominated as Auditors for the ensuing year, and had declared their willingness to accept office if elected, except Mr. Thompson, who does not seek re-election:—

Hodgkinson, William, 198, Upper Whitecross Street, E.C.
Lescher, Frank Harwood, 60, Bartholomew Close, E.C.
Stacey, Samuel Lloyd, 300, High Holborn, W.C.
Thompson, Henry Ayscough, 22, Worship Street, E.C.
Watts, William Manning, 32, Lower Whitecross St., E.C.

The President said he was sure the Society would be sorry to lose the services of Mr. Ayscough Thompson as auditor, but in consequence of his eyesight not being so good as formerly, and the increased work of the audit, he felt that it was proper to retire. It was the duty of the Council in these circumstances to nominate someone in his place, and he would therefore, on the suggestion of Mr. Thompson himself, nominate Mr. Hopkin, 16, Cross Street, Hatton Garden.

The nomination was unanimously acceded to, and the thanks of the Council accorded to Mr. Ayscough Thompson for his valuable services.

Elections.

Chemist and Druggist.

Joseph Hobley, of Llanberis, a chemist and druggist, registered as being in business on his own account before August 1, 1868, having tendered his subscription for the current year, was elected a "Member" of the Society.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society.

Allen, Frederick Charles	Walsall.
Charles, Thomas	Hanley.
Constance, Herbert Edward	London.
Crofts, John Ernest	Birkenhead.
Francis, William Henry	London.
Graham, Robert	Paisley.
Hutchin, William Francis W.	Saffron Walden.
Keeling, Arthur Gadsby	Walthamstow.
Neale, John	King's Lynn.
Smith, John Henry	London.
Tilley, Joseph	Bristol.
Wardle, Thomas	Burslem.
Wilcock, John	Lancaster.
Wrack, Frederic George	Bridlington.

ASSOCIATES.

The following, having passed the Minor examination and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Arthur, Samuel	Redruth.
Collen, William Cresswell	London.
Hill, Charles Walter	Leeds.
Jackson, Frederick	Manchester.
McLanachan, John	Sheffield.
Ray, Charles	Eastbourne.
Sapsed, William George	London.
Shannon, Robert James	Birmingham.
Stewart, Alexander Kennedy	Kilmarnock.
Taylor, Edward	Tonbridge.
Thwaites, Frederick	Bishop Auckland.
Tupholme, Frank	London.
Wilkinson, Robert	Kirkham.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Baker, Sydney John	Exeter.
Berridge, Oliver Gillett	Leicester.
Bloomer, Joseph	Cradley Heath.
Bowie, George	Aberdeen.
Brown, Frederick Edward	Ipswich.
Capell, James Ralph	Kettering.
Clarke, Charles Henry	London.
Golding, Frank Oliver	London.
Greaves, William	Ironville.
Hart, Edgar Thomas	Rochester.
Horry, William Thomas	Boston.
James, Hugh	Bodedern.
Jeeves, Henry	Brighton.
Jones, John Morgan	Brechfa.
Lee, Charles Henry	Melton Mowbray.
MacBean, James Barnet	Edinburgh.
Mart, Oliver George Russell	London.
Middleton, David	Aberdeen.
Miner, Major Thomas	Walsall.
Thomas, Ivor Edward	Merthyr.
Vallance, Arthur Clayton	Mansfield.
Watson, Edwin Joseph	Birmingham.
Watts, John William	Finchley.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Restoration to the Register.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

Thomas Williams, 1, Cleveland Villa, Northcote Road, Clapham Junction, London, S.W.
Alfred Yeatman, Chagford, Devon.

The Registrar reported that—
Richard Lewis, of Llansaintffraid, Montgomeryshire, having made a statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and this declaration having been duly supported by a qualified person, his name had been placed on the Register.

Honorary Members.

The President said the next business on the agenda was the selection of names for nomination as Honorary Members to be elected next month, but inasmuch as the bye-laws were now under consideration, and it was proposed to make some alteration in the regulations for electing Honorary and Corresponding Members, he apprehended the Council would prefer leaving the question in abeyance for the present.

This view being acquiesced in, no names were mentioned.

Reports of Committees.

FINANCE.

The report of this Committee was read and confirmed, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to the widow, aged 58, of a member from 1841 to 1877. Applicant had a previous grant of £15 in October, 1881. Is in ill-health, and has a daughter in ill-health also. Hampshire.

£5 to the widow, aged 44, of a former member. Surrey.

£15 to the widow, aged 51, of a registered chemist and druggist. Surrey.

£10 to a registered chemist and druggist, aged 72, formerly in business for forty-five years; became paralysed in 1881. Yorkshire.

£10 as the usual quarterly allowance towards the support of the Isherwood orphans.

One other application had been deferred for further information, and four had not been entertained.

The report and recommendations of the Committee were adopted on the motion of the Vice-President, who stated that a very satisfactory report had been received with regard to the boy Isherwood, who had recently been apprenticed.

FREEHOLD INVESTMENTS.

This Committee presented a report, which was considered in committee.

After a long discussion the report and recommendation were unanimously adopted.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
February	Day	545	32	11	22
	Evening	174	20	2	8

Circulation of books.	Town.	Country.	Total.
		No. of Entries.	
February	175	131	306

Carriage paid, £2 5*s*.

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Journal of the Chemical Society, 1883.
Berichte der deutschen chemischen Gesellschaft, 1883. From Mr. Walter Hills.
Johanson (E.), Heizwerth eines Torfes.
— Ein Ei im Hühnerei.
— Zur Bestimmung des Alters der Biere, 1883.
— Zur Frage der Brennmaterialien.
— Zur Untersuchung von Zuckerwaren.
— Eine russische Steinkohle.
— St. Petersburger Hausseifen.
— Ein Desinfectionsmittel.
— Zur Gerbstoffbestimmung.
— Ein Patentmittel. From the Author.
Fourth Annual Report of the State Board of Health, Lunacy, and Charity of Massachusetts, 1883. From the Board.

The Committee recommended the purchase of the undermentioned works:—

Codex medicamentarius, Pharmacopée française, 1884. 2 *copies.*
Parrish (E.), Treatise on Pharmacy, 5th ed. 2 *copies.*
Proctor (B. S.), Lectures on Practical Pharmacy, 2nd ed. *A third copy.*
Remsen (I.), Principles of Theoretical Chemistry, 2nd ed.
Thudichum (J. L. W.), Pathology of the Urine, latest ed.
Ure (A.), Dictionary of Arts, Manufactures and Mines, 7th ed., vols. 1, 2, 3.
Watt (A.), Art of Soap Making.

Curator's Report.

The Curator had reported the attendances in the Museum during February to have been:—

	Total.	Highest.	Lowest.	Average.
Morning	585	42	15	28
Evening	98	20	1	3

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimens of crystallized Jambosin and of Di-mercuric chloride atropine hydrochlorate. From Mr. A. W. Gerrard.
Specimens of the resin of *Xanthorrhœa Greiossii.* From Mr. H. Hart, West Australia.
Specimens of Red and of White Kola Nuts and of the fruits of *Myristica surinamensis.* From Messrs. T. Christy and Co.
Specimens of Kola Nuts wrapped in the leaves used for preserving them by the natives. From Messrs. Symes and Hallawell.
Specimen of Essential Oil of Limes from Trinidad. From Messrs. Wright, Layman and Umney.
Specimen of pure Cymene, prepared from Austraterebinthene by the action of Iodine upon it. From Miss E. C. Hacon, Laboratory Student.
Fresh specimen of the root of *Urginea Scilla.* From Messrs. H. Roberts and Co., Florence.
Specimen of a variety of Sarsaparilla collected in Paraguay. From Messrs. Burgoyne, Burbidge, Cyriax and Farries.

An application for the loan of specimens from the Museum to illustrate a lecture on Tea had been received from Mr. Hasselby, of Doncaster.

The Professors had attended and reported satisfactorily of their respective classes.

A letter had been received from the India Office notifying the dispatch of a further collection of cinchona barks for the Society's Museum.

The President made an explanation in Committee as to inquiries he had been requested to make with regard to obtaining the paper required for the Journal on better terms. He then moved the adoption of the report.

Mr. Williams seconded the motion, which after some conversation was carried unanimously.

GENERAL PURPOSES.

The report of this Committee was taken as usual in committee. It included the reports from Professors

Bentley and Redwood as to the class examinations at the end of the first five months course.

Professor Bentley had reported that fourteen students had competed for the prizes, of whom a large proportion were worthy of distinction, and the general result was most satisfactory. He had never had a better conducted class, and the system of *vivâ voce* examination after each lecture had been found very useful. The number of students in attendance had been larger than last year.

Professor Redwood's report was also very satisfactory. He stated that the assistance he had received from Mr. Dunstan and Mr. Ince had contributed to make the instruction provided such as ought to be satisfactory to the students, and he believed it had been generally appreciated. Mr. Dunstan, in addition to his lectures on organic chemisty, had given six supplementary afternoon lectures. Mr. Ince had given thirty-eight demonstrations, preceded by short lectures, on practical pharmacy and dispensing.

The attendance at all these lectures and demonstrations had been regular, and the conduct of the students unexceptionable.

The Committee, having opened the motto envelopes to ascertain the names of the successful competitors, recommended that the following awards be made:—

Chemistry and Pharmacy.

Bronze Medal		Fraser McDiarmid.
Certificate of Merit ...		Ernest John Eastes.
" "		Robert Wynne Chas. Pierce.
" "		Frederick Edward Johnson.
" "		George Frederic Callaway.

Botany and Materia Medica.

Bronze Medal		Fraser McDiarmid.
Certificate of Merit ...		Ernest John Eastes.
" "	Equal.	Frederick Edward Johnson.
" "	Equal.	Richard Henry Norman.
" "	Equal.	Josiah William Steward.
" "		Robert Roberts.
" "		Robert Wynne Chas. Pierce.
" "	Equal.	Ernest Haworth Earle.
" "	Equal.	Albert Wilson.

The report also included the usual letter from the Solicitor, reporting the progress of cases placed in his hands.

Several other cases of alleged infringement of the Pharmacy Acts had been considered by the Committee. In some cases proceedings were recommended to be taken, and in others further information was desired.

The President having given details of some of the cases referred to, a long discussion ensued with reference to one of the cases recommended for prosecution.

On resuming, the report and recommendations were unanimously adopted.

The North British Branch.

The President, referring to the resolution passed a short time ago authorizing the purchase of premises in Edinburgh suitable to the requirements of the Society, stated that an opportunity had been presented for purchasing a house in York Place, with a garden at back and stable in the rear. It was well situated and larger than was at present required, and an offer had been made for it. A condition was imposed by the vendors that no lettering or sign board should be affixed to the walls of the house for a period of ten years, and this condition he thought might well be acceded to.

Mr. Greenish asked what amount would be required to make the house suitable for the purposes of the Society.

The President said he believed about £200 would cover it. He added that a communication had been received from the Council of the North British Branch recommending this purchase.

The Council went into committee to consider the details of the proposed purchase.

Mr. Young said there would be some little expense in connection with moving and making various arrangements in fitting up the new building, but he did not think there would be much difference between what the Society was now paying and what it would eventually have to pay and he believed the step would give an immense impetus to the Society in Scotland. During the last forty years it had been growing, but none of the places in which it had been located was at all equal in importance to this one, or at all in keeping with what might be wished.

The President said he thought it might be taken that the new building would not cost more than £100 a year. Edinburgh was an academic city and it was very desirable that the Society should show medical men there that it was progressing.

Mr. Hampson said it appeared to him the purchase was very eligible, as it seemed to be just the kind of property the Council had been looking for. There was one consideration, however, and that was as to whether the Scottish Branch had ever paid. He did not think it had; but still he thought the members of the trade would in future show their loyalty to the Society, and give more encouragement to it. It was absolutely necessary that the Society should be well represented in Scotland, and the purchase was desirable on that account; but still he hoped Scotch chemists and druggists would consider it also to their interest to help forward their common objects by joining the Society.

Mr. Borland said that he was quite alive to the remark made by Mr. Hampson that many Scotch chemists and druggists had not supported the Society in the way they might have done; but it might be considered that in a place like Scotland, where there were only one or two chemists in a locality, there was great difficulty in bringing the men together. They had not the facilities which existed in the large towns of England to call meetings, and they probably did not meet each other once a year. He had several times expressed an opinion to his friends that by a little exertion on the part of those who took an interest in the Society, there would be no great difficulty in adding to the members, and he was quite sure it only required a little explanation of the benefits to be derived from the Society to add largely to its numbers. There was no antagonism whatever to the Society in Scotland, but there was this difficulty, that before anyone could be proposed as a member he must be known to a member of the Council, and he had had that difficulty put before him within the last few days.

Mr. Young agreed with what Mr. Borland had said; he was happy, however, to tell Mr. Hampson that he had lately had the pleasure of auditing the accounts of the North British Branch, and was pleased to find that it was in the favourable position of being able to pay all its debts.

Mr. Bottle said there need be no difficulty in Scotchmen joining the Society. At the last meeting he nominated a Scotchman, because, although personally unknown to him, he was represented to him, by gentlemen on whom he could rely, as being a fit and proper person to be elected, and, therefore, he had no hesitation in signing the nomination paper. It would give him great pleasure to propose a great many more Scotchmen as members.

Mr. Schacht congratulated the President on the success of his endeavours.

The President said during his visit to Edinburgh, last week, he had endeavoured to impress on their Scotch friends that the desire of the Society was to make a strong pharmaceutical body for the whole kingdom, at the same time to make all allowances for geographical difficulties which might exist in the North. If the Society had not been so well located in Edinburgh in former years as it ought to have been it was to some extent the fault of the Scottish members, because whenever any suggestion had been made with regard to improving the accommodation, it had always been cheerfully adopted by the Council of the Society. He felt sure the result of acquiring this building would be to bring in a large number of new Scottish members.

It was moved by the PRESIDENT and seconded by the VICE-PRESIDENT, and carried unanimously, that the house, No. 36, York Place, Edinburgh, be purchased on the terms and subject to the conditions mentioned by the President, and a committee appointed to consider and report what alterations should be made to fit the house for the Society's business.

THE MEDICAL ACTS AMENDMENT BILL.

The Secretary read the following correspondence with the Privy Council:—

Copy.

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, London, W.C.,
"*March* 17, 1884.

"C. Lennox Peel, Esq., C.B.,
"Privy Council Office,
"Whitehall, S.W.

"*Medical Acts Amendment Bill.*

"Dear Sir,—On the 12th of April last, I ventured to call the attention of the Lord President to the provisions of the above Bill in so far as they relate to the preparation and revision of the British Pharmacopœia, and a memorial on the subject from the Council of this Society was subsequently addressed to the Privy Council.

"I now beg leave to inquire on behalf of the Council of the Pharmaceutical Society if it is the intention of the Lord President to include among the amendments, which I understand are to be moved in the Committee on the Bill in the House of Lords, one providing for the formation of a Pharmacopœia Committee including pharmaceutical chemists, as well as medical practioners.

"I am, dear sir, your obedient servant,
(Signed) "M. CARTEIGHE.
"*President.*"

Copy.

"Privy Council Office, Whitehall,
"19th *March*, 1884.

"Sir,—I have submitted to the Lord President of the Council your letter of the 17th inst. and I am to state, for the information of the Council of the Pharmaceutical Society that his Lordship regrets that he does not see his way to amend the Medical Acts Amendment Bill, in the manner suggested by you, by inserting a clause providing for the formation of a Pharmacopœia Committee including pharmaceutical chemists as well as medical practitioners.

"I am, sir, your obedient servant,
(Signed) "C. L. PEEL."

The PRESIDENT said the further amendments which had been introduced were simply with regard to the proportional representation of corporations as against universities on the Medical Council. He understood the Bill was to be read a third time in the House of Lords on Thursday.

Mr. HAMPSON then moved the following resolution, of which he had given notice:—

"That this Council observes that the Medical Acts Amendment Bill, now in the House of Lords, contains no provision by which the Pharmaceutical Society or British pharmacists shall be officially recognized and empowered to prepare and revise the future editions of the British Pharmacopœia, and recommends that the Law and Parliamentary Committee be authorized to take such steps as they may think fit to remedy this omission."

He said he was aware of the unsatisfactory reply which the President had received from the Privy Council, but there was one word in it which gave him a little encouragement, viz., the word "regret." If there were a sense of regret in the department that the opportunity was not quite suitable for the insertion of the amendment in the Bill to meet the views of the Society and pharmacists generally, he hoped that in the Commons there would be an opportunity of satisfying that regret upon the part of the Lord President. They must all feel regret that the efforts of the Society last year and the support which they received had not been recognized. He believed the case of pharmacists was perfect in so far as they had a claim on the Government at this time when it was about to legislate with respect to future Pharmacopœias, and he hoped they would be able—not to use sufficient pressure, for he did not like that word—but to show the House of Commons that they had a just claim on the Government, and were entitled to be legislated for in respect of the Pharmacopœia. They did not ask for any pecuniary benefit, they simply asked for this recognition in the interest of pharmacy itself. Their claim was in no respect antagonistic to the medical profession, and in moving this resolution he felt sure that if members of Parliament understood what was wanted they were sufficiently reasonable to meet them in a proper way.

Mr. SYMES, in seconding the motion, said it would not be necessary to occupy time by putting forward any argument in favour of the principle which the members of the Council had already recognized. They all felt the importance of this matter and had previously taken such steps as they thought were desirable to support the position they maintained. Unfortunately the Bill did not reach a sufficiently advanced stage in the House of Commons last session, or undoubtedly they would have accomplished what they desired. He feared the word "regret," which had been alluded to, was merely a figure or speech.

Mr. BOTTLE supported the motion.

Mr. WILLIAMS asked how far this resolution would give power to the Committee to proceed. Would it be authorized to issue petitions, etc., as was done last year?

The PRESIDENT said he certainly understood so.

The VICE-PRESIDENT said he presumed that, apart from any agitation, an endeavour would be made to get a clause inserted in the Bill when it reached the House of Commons.

Mr. HAMPSON said the object of the resolution was to place the matter in the hands of the Committee, which would of course make the best use of its time, so that when the Bill came to the House of Commons some member should move an amendment on the lines desired.

Mr. YOUNG thought everyone would accede to the proposition.

Mr. GREENISH also supported the motion, but said the matter had been so well thrashed out that it was not necessary to occupy time by repeating the old arguments over and over again. It was perhaps to be regretted that steps had not been taken earlier to remedy the matter in the House of Lords, but now the Bill was coming to the House of Commons, every possible step should be taken to get a suitable amendment inserted. If it were not done now another twenty years would elapse before a similar opportunity would occur, and he trusted every member of the Council would throw his whole heart into the matter, and that every effort would be made to carry out the principle of the resolution.

Mr. RICHARDSON also supported the motion.

Mr. BORLAND suggested that on the previous occasion the petition which had been prepared stated that it was on behalf of pharmacists and medical practitioners, and he thought it a very important point that medical men should be asked as far as possible to give their aid and countenance to the movement. Pharmacists did not aim at interfering with the introduction of any medicine into the Pharmacopœia. Those matters would be left entirely to the medical profession. It was only with reference to the practical part of pharmaceutical work that they aspired to have any voice in the question. He might repeat what he had formerly said, that the various members of Parliament with whom he had conversed on the subject gave their cordial support to the movement.

The PRESIDENT said no doubt Mr. Borland's remarks would be fully borne out, and that members of the medical profession would in large numbers support the proposition. With regard to what Mr. Greenish had said he might state that on his own responsibility, after consulting one or two other members, he had thought it better not to take any steps in the House of Lords, but to wait until the Bill had been introduced into the Commons before moving any further.

The motion was then put and carried unanimously.

THE CONVERSAZIONE.

The PRESIDENT said a letter had been received from the authorities of South Kensington, giving permission for the use of the Museum on May 21 for the annual Conversazione.

PATENT MEDICINES CONTAINING POISON.

The SECRETARY read a letter which had been received from the Halifax Chemists' Association, containing a resolution which had been passed on the subject of misadventures arising from the use of patent medicines containing poisons, and suggesting the urgency of new legislation, whereby the presence of such poisons should always be indicated by the makers thereof, and the sale of articles containing them restricted to those who alone were qualified by training and education to deal therein.

A communication on the same subject was also read from the Society's Local Secretary at Sheffield.

ERRATUM.—At page 724 the name of "Edward Peck, Ely," published in the list of "Apprentices or Students," should have appeared in the list of "Associates."

EVENING MEETING.

Wednesday, April 2, 1884.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

The last Evening Meeting of the Session was held on Wednesday, April 2. The minutes of the preceeding meeting having been read and confirmed, a paper was read on—

AQUEOUS EXTRACTION OF CINCHONA BARK.

BY PROFESSOR REDWOOD.

The paper is printed on p. 797.

The PRESIDENT, in inviting a discussion, suggested that it should be confined exclusively to the subject of liquid extract of cinchona. He would only say, in passing, that the Professor had very ingeniously dropped his old friend and taken to the new one. He should be glad if he had thrown his first love over with something like courage. Possibly there were some gentlemen present who might have something to say for the so-called liquid extract of cinchona which now existed in the Pharmacopœia. With all due respect to the Professor, he must say that he had weakened the force of his argument by the first two paragraphs of his paper, for, in one place he referred to the value of the existing preparation, and then he stated in so many words that practically it was not very valuable.

Mr. GILES requested that before the discussion commenced Professor Redwood would state what he meant by quinovin.

Professor REDWOOD said that he found that the term was very generally used to represent a bitter amorphous extractive matter which was capable of being taken out from cinchona barks, and which after concentration was precipitated by dilution.

Dr. PAUL said that he had listened to the paper with very great surprise, on account of the remarkable discrepancy between the statements contained in it and the position which Professor Redwood took up with regard to the liquid extract of cinchona on a previous occasion. About a year ago he (Dr. Paul) brought before the meeting some data which led him to conclude that the liquid extract of cinchona was not altogether what it was commonly believed to be, or what he believed such a preparation ought to be in regard to the drug from which it was prepared. One objection which he raised against the liquid extract of the Pharmacopœia was its invariable deficiency in the amount of alkaloids which it ought to contain, and that therefore the recommendations which were given of it were misleading to medical men. On that occasion Professor Redwood defended the preparation and the method of preparing it, and he characterized the objection that it did not contain the medicinal constituents of the bark as a very weak objection. The present paper, however, appeared to be a perfect recantation of the position which Professor Redwood previously took up. He now said that there was a strong ground of objection to the official mode of preparing liquor cinchonæ. That was precisely what he (Dr. Paul) had said a year ago. Indeed, Professor Redwood's present statement appeared to be a confession which admitted all the charges which he (Dr. Paul) made against the preparation and the process by which it was prepared. The Professor might, however, have been somewhat more candid in his confession than he had been. In consequence of the vigorous defence which Professor Redwood made on the last occasion, he (Dr. Paul) was discouraged from following out the matter and had remained passive ever since. His objections to the official process were not received with favour, and there did not seem any prospect of a proposed substitute being better received; therefore when Professor Redwood spoke of the difficulty which he had had to get his friends to undertake the investigation of the subject it must be remembered that the difficulty was somewhat of his own creating. In commenting upon the chief objection to the liquor cinchonæ, that it did not contain all the medicinal constituents of bark, Professor Redwood instanced the infusion of camomile and asked who in his senses would think of objecting to that infusion because it did not fully represent all that was active in the camomile flower. It was remarkable that, after such a brief lapse of time, he should now come forward and abandon his former position and recommend the present preparation, because it fully represented the medicinal efficacy of the bark. It could not be supposed that in this short space of time the Professor had taken leave of his senses, and yet he now came with a recommendation which only a year ago he characterized as senseless. Then as to the material from which the new preparation was to be made, they were told that it was red bark. But what red bark? Certainly not the red bark of South America, which, however valuable it might be for making tooth powder, had very little febrifuge value, and would not serve for making the liquid extract. He apprehended that the bark used was the Indian red bark, which a year ago he was told was so utterly outside the pale of official pharmaceutical recognition that he was making an unwarrantable assumption in presuming to bring forward experiments made with that bark to show that the process in the Pharmacopœia was useless. His experience of the red bark of India, notwithstanding the favour with which it was regarded by some persons, was that it was about the worst bark which could possibly be used. It contained much objectionable material, which resembled extract of kino more than anything else, and he should judge that it was about the most unsuitable of any for pharmaceutical purposes. There was plenty of cinchona bark of the true calisaya or officinalis type, which he regarded as preferable, and which possessed the advantage of having very little of the red offensive looking and nauseous material which was precipitated by water; such bark contained a large percentage of alkaloid in which quinine preponderated. They were told at the last discussion that the reason that he obtained unfavourable results was that he used the Indian bark, which was a material not ordered in the Pharmacopœia. He (Dr. Paul) took it that in the lapse of time Professor Redwood had recognized the validity of the objections which he (Dr. Paul) raised on the former occasion, and that he had now sought to devise a process by which those objections could be avoided. As to the process itself, it consisted in treating Indian *Succirubra* bark, he supposed, not with water, but with dilute acid. He could not accept the representation that this was an aqueous treatment, seeing hydrochloric acid was employed. He should like to see some data which would enable them to judge how far the preparation, made with hydrochloric acid, really did represent the bark in every respect. That he believed to be the chief point about the whole of the preparations of bark. A great deal had been said about the relative efficacy of different preparations and medical opinions with regard to the water preparations had been alluded to. No doubt those opinions were deserving of respect, although they were not altogether intelligible in the present state of our knowledge. It appeared that the very strong predilection amongst medical men in favour of the decoction was due, not to the constituents which it contained, but to the manner in which the constituents were presented to the stomach. In all kinds of cinchona bark, he believed, the principal part of the alkaloids was in combination with cinchotannic acid, and in that form of combination the alkaloids were very sparingly soluble in water. The consequence was that the infusion which was made with cold water was the weakest of any; the decoction was stronger, but though the solubility of the cinchotannates was greater in hot water than in cold, a large quantity of cinchotannate was deposited when the water cooled. What remained was in the same state of combination as in the bark itself, and that, he believed, was one of the reasons why the decoction was preferred to any other preparation. With regard to the liquid extract, he thought that the same condition ought to be maintained, and that an attempt should be made to avoid the elimination of the cinchotannic acid, and its decomposition, which took place very readily alkaloids in the state in which they existed in the bark. when it was liberated, so as to obtain a solution of the Professor Redwood had spoken of certain "worthless" constituents being eliminated. He (Dr. Paul) failed to see on what authority Professor Redwood condemned those constituents, or why he assumed that the alkaloids contained in his finished preparation were in the state in which it was desirable they should exist. This must be left for further inquiry. His (Dr. Paul's) own opinion was that the use of hydrochloric acid in preparing liquid extract was decidedly objectionable. Professor Redwood had stated that there was nothing in the preparation made by the process which he had now described which was not freely soluble in water. Consequently there was no cinchotannate of the alkaloid, and it might be inferred that this had been decomposed. This was in fact shown by the absence of turbidity on diluting the new preparation with water. The cinchotannate was, however, precisely the constituent which it was desirable to retain in a liquid extract. As to the exhaustion of the bark, there were no data showing that the new process was efficient. He was inclined to doubt whether treatment with weak acid would extract the whole of the alkaloids. The objections which he urged to the process were chiefly made on chemical grounds. He would leave the pharmaceutical part of the discussion to others who were more competent to deal with it.

Mr. Giles said that he thought that it was perfectly immaterial whether Professor Redwood had changed his opinion or not, but he should like to say a word for the much abused old liquid extract. Some time ago having occasion to examine liquid extract of cinchona he obtained specimens of all the preparations known to the market and amongst them, two samples of the Pharmacopœia liquid extract, one from a highly respected retail house, and the other from a manufacturing firm. The former contained 1·498 per cent. and the latter 1·860 per cent. of basic alkaloid. Pharmacopœia Calisaya bark ought to contain 2 per cent. of basic alkaloid; and if those extracts which he examined were made from Pharmacopœia Calisaya they showed a very good result, for they contained nearly all the alkaloids that ought to have been present in the bark. He also examined some extracts which were very much advertised as being superior preparations. One of these contained 1·495 per cent. of the alkaloids, and this was by far the highest percentage among those much advertised preparations. Battley's preparation gave a higher percentage, but for certain reasons he did not include it in the category. Hence, having regard to the lights which existed fourteen years ago, when the Pharmacopœia was compiled, the old Pharmacopœia preparation was not so disreputable. His experience was that medical men had very great faith in the old liquid extract when it was properly prepared. He believed that the reason was that the bark contained constituents of very great value, which were not alkaloids. What was wanted was a preparation of bark. If simply the active principles were required the alkaloids themselves could be used. He was very suspicious when he heard his friend, Professor Redwood, proposing to turn out what he called "quinovin." It was a dangerous thing to begin turning out anything, and he did not see the necessity for it. With regard to the mode of preparation, he was very suspicious about the direction to macerate at a temperature of 180° F. His experience was that no good was to be got from a high temperature. Another part of the process given in the paper consisted in adding distilled water to the concentrated percolate and stirring together while a precipitate was forming. But he did not see why there should be any precipitate formed at all. He had evaporated large quantities down to a solid extract, which he found perfectly soluble. It was true that he did not use a temperature of 180° and that the evaporation was performed *in vacuo*. He questioned whether the process of precipitating by soda in the manner directed for estimating the percentage of alkaloid in the solid extract would be found to be reliable. He thought the precipitate so obtained would be likely to consist largely of cinchotannate and would give too high a result; but that was a detail which might be amended. His impression was that they knew very little about bark, and that it was a rash thing to say what part of it had a medicinal value and what part of it had not. He held that all the surroundings of the alkaloids were important, and that the real object in making an extract was to get out all that was soluble and could be retained in the soluble condition. It was an easy thing for the Professor to cut the Gordian knot, by precipitating some of the material and filtering it out if he could not keep it in solution, and thus to obtain a soluble residuum. A soluble preparation might always be obtained in that way, but he did not think that that was a fair way of overcoming the difficulty. The Professor said, "The small quantity of hydrochloric acid used in the process is sufficient to ensure the entire removal of the alkaloids from barks of average and even more than average quality." He doubted that statement entirely. He did not know whether Professor Redwood had examined the marcs afterwards; but he (Mr. Giles) had often found 1 per cent. of alkaloids left in a bark containing originally 7 or 8 per cent., although hydrochloric acid was used and the percolation was conducted precisely as directed in the present paper.

Professor Redwood said that he was prepared to show that there were no alkaloids left in the liquid.

Mr. Giles said that the recognition of the use of hydrochloric acid was an important advance in the process. Unless an acid was used there would be a waste of alkaloid. With all due respect to Dr. Paul, he believed that the hydrochloric acid dissolved the cinchotannates of the alkaloids as cinchotannates. He knew that, having dissolved them out, they could be got back again as cinchotannates, though that did not show that they had not undergone a change in the meantime.

Mr. HOLMES said that he had tasted the extract on the table, and he found that the astringency had not been destroyed by the hydrochloric acid. He believed that hydrochloric acid was always present in the gastric juice, and therefore if the preparation was not submitted to the action of hydrochloric acid before it entered the stomach, it certainly was afterwards.

Mr. DUNSTAN said that he should think it extremely probable that the hydrochloric acid decomposed the cinchotannates, forming cinchotannic acid and chlorides of the alkaloids. He supposed that when Mr. Giles said that he could get back the cinchotannates, he meant by the addition of ammonia.

Mr. GILES said that he got them back by treating with acetate of soda.

Mr. DUNSTAN, resuming, said that that amounted to the same thing. Assuming that they could not get the cinchotannates out by water alone, the next best thing was to get out the cinchotannic acid and the alkaloid separately. That seemed to be what Professor Redwood did. He was struck with one point in connection with what Professor Redwood supposed to be the necessity of making a solid extract of cinchona. It seemed to him that a standard liquid extract could more easily be got by estimating the alkaloid in the strong solution, and then diluting it to the requisite extent. He supposed that it was a troublesome operation to evaporate the solution to dryness. On the other hand, if it was thought desirable to have a soluble solid extract in medicine it seemed unnecessary, if this were standardized, to have a separate liquid extract. During the reading of the paper he recollected very forcibly a remark made by Professor Huxley, which was that a scientific man should be strangled when he arrived at the age of fifty, for he then became an obstacle to progress. Professor Redwood, however, was a proof to the contrary, for he was now taking a decided step in the direction of progress in advocating a standard liquid extract which contained a specific amount of alkaloid.

Professor BENTLEY said that he imagined that the great advantage of using succirubra bark was, first, that it contained a good amount of alkaloids; secondly, that it was not very liable to vary; and thirdly, that a regular supply could be obtained. And in addition to these advantages it was a bark which could be readily recognized, and it could be generally procured free from any serious adulteration. Those were very important considerations in the selection of a bark for general use. succirubra had high authority for its use, for Dr. Flückiger recommended it some years ago, although he said that in certain respects it was not equal to some other barks. It was the sole bark recognized in the German Pharmacopœia, and it had been introduced into the Pharmacopœia of the United States. It was also one of the barks mentioned in the new Paris Codex. Mr. Holmes had also ably advocated the use of the red bark, and therefore it did not come before the meeting as something which was unknown. He did not altogether agree with his colleague with regard to the turning out of certain substances. Bark contained many constituents, and it was not known how one substance might modify the action of another. He was speaking exclusively of Succirubra bark, which was obtained from plants cultivated in India and elsewhere.

Mr. WALTER HILLS, referring to the statement in the paper that the author had had some difficulty in persuading his pharmaceutical friends to publish their modes of preparation, said that, after that discussion, and after the change which had been made, they might hope that those who had worked at the subject would make known some of the results of their work.

Mr. TANNER said that he was very pleased to find Professor Redwood advocating a liquid extract representing a less amount of bark than the Pharmacopœia did. In the Pharmacopœia preparations, four ounces of bark were used, and that on all hands was shown to be an unnecessary concentration. With regard to Mr. Giles's remarks about the assay of certain samples of liquid extract, he wished to ask Mr. Giles whether he took into account the fact that the Pharmacopœia used four ounces.

Mr. GILES said that he had not done so. He had overlooked that circumstance when making the comparison, which should have been confined to the relative alkaloidal strength of the pharmacopœial and other liquid extracts.

Mr. HADFIELD said that the method by which Professor Redwood had got at the percentages of the alkaloids contained in the liquid extract seemed to him to be rather crude. He thought that a better result would be obtained from the solid extract of which Professor Redwood had spoken, and that the alkaloids of the solid extract would be better represented by previously obtaining an analysis of the bark. Of course this method would involve more trouble.

Dr. PAUL said that in a case of perfect exhaustion the quantity of quinine which ought to be contained in a fluid extract made from a two per cent. bark,—the minimum laid down in the Pharmacopœia—would be 35 grains in the fluid ounce. In the case of ten samples which he examined a year ago, however, the total alkaloids only ranged from 2 to 10 grains in the fluid ounce, and then the greater part was alkaloid other than quinine.

Professor REDWOOD, in reply, said that his object in taking up the subject before the meeting was to elicit from other people the best means of producing a preparation of bark which had been much extolled by medical men, and most severely criticized and condemned by pharmaceutical speakers in that room. He certainly felt that it would be more becoming on the part of those who had so strongly criticized the liquid extract of bark if they had indicated in what way a preparation having a similar object could be more satisfactorily produced. He had failed to induce anybody to take the matter up. He had been pleased to find that, in the present discussion, the criticisms had been rather criticisms of his conduct than criticisms of his paper. He had desired to ascertain the opinion of competent pharmacists as to the process which he had suggested, but he was told that he stood in a false position. He gathered that he had been looked upon as the author of the Pharmacopœia preparation, and he had been asked how he could come and condemn it. The origin of that preparation was well known, and he was not aware that it was at all inconsistent to hold by it until a better was known. That was precisely what he had endeavoured to do on the former occasion. He certainly at that time took exception to Dr. Paul's paper, because there were too many assumptions in it, and it criticized a preparation that was not the Pharmacopœia preparation at all. Years ago, when he occupied the position which was now held by Dr. Paul, nearly all the barks which came into the London market were regularly analysed by him and reported upon, and therefore he could not fail to be perfectly familiar with the chemistry of the cinchona barks. But all that he had contended for was that in the absence of any better preparation they were justified in holding to that of the Pharmacopœia. Mr. Giles had very fairly commented upon the process described in the paper, but he (Professor Redwood) did not think that Mr. Giles had in any respect damaged his position or shaken his conclusions. Mr. Giles had not shown a better way by which the valuable constituents of cinchona bark could be taken out; and he (Professor Redwood) gathered from Mr. Giles's statement that his method was the right one. Mr. Giles's strongest objection was that the process described excluded from the finished preparation something which he thought ought to be retained. Upon that point he (Professor Redwood) was at issue with him. He did not think it desirable to leave all the extractive matter in the finished preparation. What he did consider desirable was to have a preparation which would dilute with water and form a clear liquid, possessing the astringency and the aromatic flavour of good bark. He had obtained this, and he had turned out the red cinchonic and what he had termed quinovin, a body which Mr. Howard designated as a nauseous bitter which was highly objectionable in the administration of the bark. The liquid extract of the Pharmacopœia and other extracts which professed to resemble it, and even that which was ordered in the United States Pharmacopœia, all possessed the grave defect of throwing down a copious precipitate of a nauseous disagreeable bitter when they were diluted, and this was a substance which he conceived to interfere with the efficacy of the medicine. Mr. Dunstan had made a very proper suggestion with reference to the preparation of a dry extract as well as the liquid extract. He (Professor Redwood) had admitted in the paper that perhaps most producers of the liquid extract would not take the trouble of getting the dry extract first. It had been suggested to him that the dry extract would be found to be highly hygroscopic, and very difficult of preservation. He had endeavoured to satisfy himself on that point, and he had left some of the solid extract exposed in a dish in his room for a week. The test to which it had been subjected was an exceedingly severe one. He admitted that it attracted moisture and softened, but its hygroscopic character was not greater than would be expected in a dry extract of that description. He looked upon this preparation as one which would one day admit of use in medicine. An infusion or decoction would be better made from such a dry extract than by the ordinary mode, but there was a little difficulty in making a standardized dry extract of definite strength. Experiments would have to be made on that point, but he had been anxious to bring forward his present preparation before the meetings of the session terminated, in order that it might be criticized and tested by good pharmacists. He had put himself in communication with such men as merchants who were dealing with these barks, and the opinion which they had uniformly expressed was that succirubra bark would be the bark of the future, as far as application in pharmacy was concerned. It was not the object of his paper to indicate what ought to be the characters of the succirubra bark which was selected for use. That was a perfectly distinct question, in which he should look to his colleague (Professor Bentley) to take a leading part. Mr. Howard had told him that there was an abundance of succirubra bark which contained more than 10 per cent. of the mixed alkaloids. In his paper he had put out of account the low class barks; but, taking the Indian succirubra bark, he maintained that the process which he had given was a process which was applicable to any such bark, and that by means of it they could get a valuable and suitable preparation for use in medicine. He had not yet been able to get samples of all the various qualities of succirubra bark. He was desirous of taking a low class, a medium, and a high class, and ascertaining whether there was any fixed relationship between the alkaloidal strength and the amount of extractive matter, or what he might call the extractive strength, of the different qualities. He wished to ascertain whether the cinchotannic acid, and the fine aroma and flavour which he regarded as one of the most valuable medicinal constituents of the bark, bore any fixed relationship to the alkaloids which were present, in the same way that, according to Mr. Dunstan's showing, the extractive matter of nux vomica bore a uniform relationship to the alkaloids contained in the drug. This was one of the points which would have to be determined before an extract of this description could be standardized. Mr. Giles had thrown out a doubt whether the small quantity of hydrochloric acid which was used was sufficient to exhaust the bark. He could vouch for the fact that the liquid which came off at the end of the percolation gave not a trace of precipitate of any kind upon the addition of an excess of caustic soda, but remained perfectly clear. He therefore contended that the whole of the alkaloids were taken out. He might further state that after having exhausted the bark and evaporated the percolate down to a low extent he got a precipitate upon adding water. Mr. Giles had said that he need not get a precipitate. He should like Mr. Giles to explain how it could be avoided. Some barks gave a precipitate like thick mud, while other qualities gave very little; but, whatever bark was used, he held that dilution with water and the throwing down of such precipitate as might be formed were desirable, and that this method gave a result which was in every way superior to that which was obtained when the precipitate was left in the preparation.

The President said that the Professor had been wonderfully strong in reply, as he always was. It was almost a greater treat to hear him reply to than to hear him read a paper, for the reply contained a fire which the paper often lacked. He must confess that his reply was strong, except in one respect. When he told them, with the dignity of a professor, that because he found no alkaloid in the percolate, the bark was exhausted, he must forgive him (the President) for saying that the statement was extremely weak. An analysis of the bark ought to be made before they could accept the statement. Perhaps the Professor would modify his statement upon that point. He must congratulate the Professor upon the active way in which he was able to deal both with friends and with antagonists. He concluded by conveying the cordial thanks of the meeting to the Professor.

The following paper was read:—

The Approximate Analysis of the Seeds of Amomum Melegueta.

by John C. Thresh, D.Sc.

The paper is printed on p. 798.

Mr. Holmes then called attention to the recent additions to the Museum. He said that several of the chemical products had been presented by students who were in the Laboratory. Among these specimens were some fine crystals of phosphoric acid presented by Mr. Huskisson. The majority of the specimens on the table were a small proportion of a large collection of the materia medica of Brazil, which had been presented by Dr. Domingo Parodi, through Mr. W. B. Cranwell. This collection comprised nearly all the medicinal products of Brazil and the neighbouring countries. There was also a collection of medical plants recently presented by Mr. Thomas Hanbury, which had been overlooked when the herbarium of the late Daniel Hanbury was given to the Society a year or two ago.

The President said that the Council would in due course pass a vote of thanks to those donors, who were helping to make the Museum of the Society probably the finest in the world.

The meeting was adjourned until the first Wednesday in October.

Provincial Transactions.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The eleventh meeting of the session was held in the Pharmaceutical Society's Rooms, 119a, George Street, on Wednesday evening, March 26, at 9.15. Mr. C. F. Henry in the chair. There was a large attendance.

The minutes of the former meeting having been read and confirmed, the President, in intimating with regret that the Secretary had tendered his resignation, expressed the great ability with which Mr. Crowden had filled his office.

Mr. MacEwan gave in the Prize Committee's report on the Ainslie Pharmacy Prize Competition, which showed that all the candidates had arrived at a high state of excellence. The winner of the prize was Mr. Thomas Miller, while an extra prize offered by Mr. W. Aitken was carried off by Mr. A. R. Bennet. Mr. Ainslie, who presented the prizes, addressed words of encouragement and advice to the candidates.

On the call of the Chairman, Mr. W. S. Turnbull read a paper on "Elementary Botany," in which the essayist, after inculcating the necessity of practical work, proceeded to describe the structure and development of cells, vessels, roots, stems and leaves, using a series of well-executed diagrams with good effect, and concluded by drawing attention to the microscopic specimens on the table.

The President, remarking on the concise and lucid paper, was sure that it would serve its object as a help to those preparing for examination. He moved a hearty vote of thanks to Mr. Turnbull. Mr. Aitken seconded, and the motion was unanimously carried.

A discussion followed, taken part in by Messrs. Boa, Hill, MacEwan, Pirie, Robertson and Stephenson.

Afterwards queries were submitted and replied to.

Some further business having been disposed of, the meeting adjourned.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

The Anniversary Meeting was held on Monday, March 31.

The President, Dr. W. H. Perkin, F.R.S., read his Annual Report. The number of Fellows at the last Anniversary was 1247; the present number is 1324, or an increase during the year of 77. The loss sustained by death has been exceptionally great, the following having died during the past twelve months:—Messrs. R. R. F. Davey, W. Grant, W. Griffin, J. Hogarth, G. M. Hopwood, E. Hunt, C. H. Hutchinson, W. A. Peake, T. Pearsall, W. Plunkett, G. B. Robertson, F. Slinger, J. Hill Smith, W. Spottiswoode, J. T. Way, J. Young, and Sir C. W. Siemens. The rooms of the Society have been redecorated. Many additions have been made to the library, and it is hoped that the new catalogue will be completed by the end of the session. The collection of autotype portraits of past Presidents is almost complete, and is on view in the Council room.

The President then handed the Longstaff medal to Mr. O'Sullivan, as the Fellow who, in the opinion of the Council, had done most to promote chemical science by research during the last three years. Sixty-seven papers have been read before the Society since the last anniversary.

The President then proceeded to refer briefly to some of the most important advances in chemical science during the year. The numerous determinations and recalculations of atomic weights by Clarke, Lothar Meyer, Brauner, Thorpe, Dewar and Scott, etc.; the use of boiling oxygen and ethylene as refrigerating media; the freezing of alcohol at $-130°$; the use of hydroxylamine as a reagent in organic chemistry by Victor Meyer and his pupils; the improvements in the preparation of this substance by Divers, etc.; the numerous researches of Baeyer on the constitution of indigo, which may be represented—

$$\begin{array}{cccc} C_6H_4 - CO & & CO - C_6H_4 \\ | \quad\quad | & & | \quad\quad | \\ HN - C & = & C - NH. \end{array}$$

The President remarked that although there are now several processes by which this colouring matter can be manufactured, it cannot as yet be produced at a sufficiently low price to compete with the natural product. The work of Lewkowitsch on mandelic acid, of Hofmann on pentamethyl anilin, and of Victor Meyer on thiophene, etc, were also briefly described.

The address concluded with some considerations as to the influence the increasing number of laboratories and the greater facilities for the study of chemistry have had on the development of chemical science in this country.

The first thing that attracts attention is the startling and anomalous fact that the number of papers read before the Society is declining year by year; in 1880–1 it was 113; in 1881–2, 87; in 1882–3, 70; and last year it was 67. The work of our laboratories at the universities, colleges and hospitals seems to consist mainly in studying the ordinary course of qualitative and quantitative analysis and in attending one or two courses of lectures. Such an education is insufficient, it is only a preliminary part of the training. The subsequent prosecution of scientific research under proper supervision calls out all the faculties of the student, requiring independent thought, and gives an insight and vivid interest in the science which nothing else can do. In Germany the degree of Doctor of Philosophy has undoubtedly done much, as it necessitates the prosecution of original work, and now that degrees are so highly thought of in this country (though why a chemist with one of our ordinary degrees should be preferred to one who has fully given his mind to his science, and, therefore has not such a degree, it is difficult to understand); it is believed that if something analogous to the Ph.D. degree could be inaugurated in this country it would help the further advance of chemical science in this country. It is said that students cannot be induced to stay longer than is necessary to go through the ordinary course of analysis, and can this be wondered at when they do not see anything else going on of sufficient interest to make them feel that it would be a great advantage for them to stay? Would it be the case if higher work were being enthusiastically carried on? The fact that many of our students leave this country for Germany, where research is carried on with so much zeal, is a sufficient answer to this question. In conclusion, the President expressed a hope that at the Central Institute of the City and Guilds of London chemists would be trained in such a way as not only to carry out existing processes, but also to advance the chemical industries of the country by suggesting improvements and new processes, so that these industries might flourish and at least keep abreast of those on the continent.

Dr. Gladstone said that it was his agreeable task to propose a vote of thanks to the President, and at the same time to move that his address, which had been so enthusiastically received, be printed.

The vote was seconded by Mr. Howard, and carried unanimously.

The Treasurer then read his report. The total income of the Society was £4732 16*s.* 4*d.* The expenses, including the purchase of £300 stock, amounted to £3028 1*s.* 9*d.*, leaving a balance in the bank of £1704 14*s.* 7*d.* The balance was larger than had been anticipated, because an unusual number of Fellows elected during the year had paid life compositions, and because the new catalogue had not yet been completed. The principal items in the expenditure are:—Journal, £1591; library, £241; redecoration of rooms, £294; house expenses, £185; commission, £145. The assets of the Society amount to £9792 14*s.* 7*d.* As to the research fund, receipts amounted to £431; grants, £95; balance, £336. Assets, £4836 3*s.* 3*d.*

Votes of thanks were proposed to the Treasurer, the Auditors, the Officers and Council, and the Editor, Sub-Editor, and Abstractors.

After a ballot, the Scrutineers, Messrs. Greenaway and Williams declared the following officers and Council duly elected:—President, W. H. Perkin, Ph.D., F.R.S.; Vice-Presidents, Sir F. A. Abel, Warren De La Rue, E. Frankland, J. H. Gilbert, J. H. Gladstone, A. W. Hofmann, W. Odling, Sir Lyon Playfair, H. E. Roscoe,

A. W. Williamson, P. Griess, G. D. Liveing, E. Schunck, T. E. Thorpe, A. Voelcker, W. Weldon; Secretaries, H. E. Armstrong, J. Millar Thomson; Foreign Secretary, H. Müller; Treasurer, W. J. Russell; Members of Council, E. Atkinson, H. T. Brown, T. Carnelly, M. Carteighe, R. J. Friswell, W. R. E. Hodgkinson, D. Howard, F. R. Japp, R. Meldola, R. Messel, C. O'Sullivan, C. Schorlemmer.

SOCIETY OF ARTS.

Alloys Used for Coinage.

The third of the series of Cantor lectures by Professor W. Chandler Roberts was delivered on Monday the 31st ult., and treated almost exclusively of the methods by which the accuracy of weight and fineness of the alloys were ensured. A method used extensively in the middle ages, and up till quite recently in the Royal Mint, consisted of drawing the alloy across a piece of fine basaltic rock, termed a touchstone; the streak produced was compared with streaks of alloys of known composition, and thus the approximate composition of the alloy obtained. Another method more largely used than supposed is that suggested by Archimedes, its application being based on observations on the different densities of alloys. The principal electrical test lies in the amount of electromotive power generated by the alloy when placed in a corrosive fluid as compared with the amount generated by an alloy of known composition subjected to the same action, the electromotive power in each case being gauged by a galvanometer. Professor Hughes's induction balance is also sometimes employed to test the inductive properties of the alloy. Almost the only optical instrument used for the assay of alloys is the spectroscope, but the results of experiments obtained by this method have been found more delicate than utilizable. The lecturer then gave a detailed description of the chemical method of assay used at the present time in the Royal Mint, illustrating this part of his lecture with experiments. He mentioned the fact that when English standard silver is heated in air a light grey coating is formed, when the French standard silver is experimented upon a darker grey is obtained, and if a base alloy be taken the coat becomes black. This is due to the oxidation of the baser metals in the alloy. Advantage is taken of this difference in behaviour of the metals in the operation known as "cupellation." The alloy is strongly heated in a porous crucible termed a cupella; the litharge formed flows into the pores of the cupella, carrying with it all the baser metals in the alloy, and the globule of metal remaining at the bottom of the cupella consists of a mixture of gold and silver. This button of metal is hammered and then rolled into an elongated form, and afterwards boiled with nitric acid until all the silver is dissolved. The remaining gold is now in such a fragile form that the slightest touch will reduce it to powder; it is therefore hardened by slightly heating it in the furnace in order to enable it to be handled. The amount of silver dissolved by the nitric acid is determined by titration with a standard solution of common salt. The silver may exist in the alloy in such a small quantity that the nitric acid will not act upon it; in this case about three times the amount of silver is added to it, when the nitric acid not only readily acts upon the added silver, but also upon the silver previously existing in the alloy. Though the results of these experiments would be theoretically correct, it is found that a small quantity of gold and silver, especially the latter, is unaccounted for. The silver may be lost by flowing away with the litharge into the cupella, and also by a slight volatilization. In dissolving the silver with nitric acid it is also found practically impossible to separate the whole of the silver from the gold. Gold may also be lost in the process of cupellation, but the slight admixture of silver with it after having been boiled with nitric acid causes the alloy to apparently have a larger percentage of gold than is really the case. To avoid these slight errors, pieces of alloy of known composition, termed "checks," are submitted to both operations side by side with the alloy to be assayed, and from comparison with the known errors in the composition of these "checks" the composition of the alloy is calculated. The amount of fluctuation allowed between the composition of the alloys, known under the name of "remedies," has been gradually reduced since 1279, the "remedy" of gold in an alloy being now 0·2 per cent., whilst silver is allowed 0·4 per cent. Professor Roberts remarked that it was worthy of note that the Arabian alchemist, Geber, not only gives an accurate description of the process of cupellation as employed by himself, but also describes of what materials and in what manner the cupella itself is made, which method remains at present unaltered. The method proposed by Gay-Lussac for the assay of alloys is thought practically useless, and is only used as a means of verification.

Parliamentary and Law Proceedings.

Suicide by Prussic Acid.

An inquest was opened at Southampton on Friday, March 28, before the Borough Coroner, Mr. William Coxwell, concerning the death of Henry William Collis, aged 19 years, supposed to have committed suicide by taking prussic acid.

Mr. H. W. Collis, sen., deceased's father, said he was told his son was in a fit and went to him, finding him about fifty yards from his house. He appeared to witness to be very much intoxicated, and with assistance he was brought home. Still believing him to be intoxicated, from the very strong smell of beer about him, he laid him on the hearthrug, and put a pillow under his head. He was with him about ten minutes, and then left him alone. After about twenty-five minutes he found his son very warm, the perspiration standing on his forehead; heavy breathing had ceased, and he was breathing very little. Witness being uneasy about him felt his pulse, and finding it was not strong enough for a strong man, he felt in the region of his heart, but could feel no pulsation there. Witness took up his coat to lay over him to keep him warm, when a bottle fell out of it, or he saw it, marked "Poison"—that produced was the same. Directly he caught sight of this he ran to Dr. Archer's, but he not being at home he hurried to the shop of Mr. Gibson, the chemist, whose label was on the bottle, and from what he told him he went to Dr. Palk, who came directly, and pronounced him dead. Questioned as to the state of his son's mind, Mr. Collis said he never knew a more cheerful lad, and he was not aware that his mind was affected in any way.

James Edward Gibson, chemist, of 34, Above Bar, stated that on Thursday morning, between nine and ten o'clock, deceased came to his shop and wished witness to go to his father's to poison a dog for him; but witness told him that being single-handed he could not leave his shop. Deceased said he was very sorry, for the dog had met with an accident the previous night. Deceased then asked if witness would let him have the poison to take up to his father, saying that he was in a hurry to get away by an early train and the dog was suffering, and he wished to get rid of the animal before he went away, and knowing him, and his father also, witness let him have the poison, subject to the precautions prescribed by the Act, viz., labelling the bottle "Poison" and getting deceased to sign for it on the record, giving the date, quantity, and purpose for which it was required. The Act further required that if the purchaser was not known there was to be a witness introducing him, but knowing the deceased personally this was not required here. He served him with two drachms of prussic acid, deceased suggesting a larger bottle as more convenient to administer to the dog. Witness produced his book containing the signature of the deceased, whom he had known two or three months, but his father a longer period. Deceased was quite rational and collected. He knew the deceased not perhaps personally, but as the son of Mr. Collis, and he had spoken to him. He considered his knowledge of deceased sufficient to fully warrant him under the Act in serving him with the acid.

By Mr. Killby, solicitor, who had watched the case in the interest of the witness: He believed deceased's story as to the purpose to which he intended to apply the poison, for it was a most plausible one, and witness considered he had faithfully carried out the requirements of the Act.

Dr. Henry Palk stated that he was called to see the deceased at his father's residence in Portland Terrace, and found him in the front room, on the hearthrug, quite recently dead. He made a superficial examination and found the face and neck very livid, the hands and nails likewise, the pupils dilated, and the muscles very flaccid. Mr. Collis handed him the bottle produced, which, though empty, still smelt strongly of prussic acid, and all the symptoms were concurrent with deceased having died from this poison, though without a *post-mortem* examination he could not say positively that this was the case. If deceased took all the prussic acid that was sold to him his death would have ensued in a few minutes, and he could not understand, if such was the case, how he lingered so long alive in the house. A very much smaller quantity than deceased bought would have been fatal; twenty drops would have killed him, and he bought six times that quantity, and his death would have been instantaneous almost had he imbibed the whole amount —he could not have lived over ten minutes, and probably it would not have been more than three or four minutes.

The Coroner said, after the evidence, seeing the doctor could not state positively the cause of death, he thought it would be necessary to adjourn the inquiry and have a *post-mortem* examination of the body made, and the inquiry was subsequently adjourned.

At the adjourned inquest,—

Dr. Henry Palk stated that upon opening the body the odour of prussic acid was most overpowering. He examined the heart and lungs, and found them healthy, but the veins gorged with fluid, dark-coloured, blood. This would be consistent with poisoning by prussic acid. He examined the stomach and found it contained a quantity of undigested food; the mucous membrane was somewhat congested. He took away a portion of the stomach and its contents, and had since analysed both, and found undoubted proofs of the presence of prussic acid, and he had no doubt at all that death arose from poisoning by taking prussic acid.

Mr. Gibson, the chemist who sold the acid, stated, in reply to the Coroner, that he was registered as a chemist in 1879. The Coroner, referring to the official Register of Chemists and Druggists, which he said was sent to him by the Secretary of State, and was supposed to contain a complete record of the certificated members of the trade, remarked that he could not see his name in the Southampton list; but Mr. Gibson said he was registered at Middlesborough-on-Tees, and he pointed to the record as giving his name there.

The Coroner asked Mr Gibson if he did not consider it his place to see that his name in the book was transferred to Southampton now that he lived there; but he replied that that was for the local secretary who assisted in compiling the book to look to. He had his certificate, not with him, but at his shop.

After the jury had consulted in private, the Coroner announced that the jury had arrived at a verdict that the deceased while of unsound mind killed himself by taking prussic acid. The Coroner added that the jury hoped that Mr. Gibson would be more careful in future in selling poison at his establishment without witnesses, a remark against which one of the jurors protested.—*Hampshire Independent.*

Correspondence.

Tincture of Hyoscyamus.

Sir,—Allow me to say that I do not consider there is a particle of evidence in Mr. Gilmour's paper to show that proof spirit is a better menstruum than rectified spirit for tincture of henbane. To compare the values of tinctures by their colours, amounts of extractive, and turbidity-giving property is quite valueless; when we know, as in this case, the active principle happens to be a colourless alkaloid. What is wanted is a determination of their alkaloidal values, and I suggest Mr. Gilmour's attention to this.

Another matter I would refer to is that Mr. Gilmour did not find his three weeks' old tincture had become acid, as I suggested it would do. My experience on this point is quite the contrary. I have before me samples of three tinctures of henbane, not an hour made; all are distinctly acid. I have another sample three weeks old; its acidity is most marked. I have purchased four other samples; all are acid. I may state generally that dried leaves give soluble matters having acid reactions.

With reference to annual and biennial henbanes, I regret with Mr. Gilmour that we have no means, seeing the broken state in which the annual is sold, of identifying it; but apart from this, what is most needed is accurate experiments on the comparative values of the two sorts; at present their reputations seem to rest almost solely on prejudice instead of scientific evidence.

Pharmaceutical Apparatus.

Sir,—I have read with great pleasure the notes on pharmaceutical apparatus by Dr. Charles Symes, and I admire the simplicity and convenience of the arrangements figured. I have myself had to work with large and cumbersome apparatus where the skill of the man in connection with the pan was strikingly exemplified. I have to confess that modern ingenuity is in advance of ancient experience.

Yet I congratulate Dr. Symes on having had the courage to retain the form of still head which has been in use for centuries, and the pattern of which may be seen in Egyptian sculpture. It may be specially trusted in large operations and in the case of highly volatile preparations. When there might be a danger of overdrawing, the shape itself is an additional safeguard.

I base these remarks on two circumstances. First, that in continuous distillation during the season, we were uniformly successful with this shape, and not so with others. Secondly, when a few years ago small private stills of from two to four gallons capacity were introduced into several London families, no other shape was found equally safe or advantageous in domestic employment; that is, in inexperienced hands.

SPIRITUS ÆTHERIS NITROSI: COMPOSITION IN RELATION TO DETERIORATION.*

BY PETER MACEWAN.

"What this spirit is," says Professor Redwood,† "has hitherto eluded investigations; it contains nitrite of ethyl, aldehyde, and probably other compounds, but in what proportion it is extremely difficult to indicate, all that we can say is that it always contains the same proportion of the same ingredients."

Recognizing fully the difficulty here alluded to, it is with some hesitancy that I approach the subject, for though Professor Redwood made this statement about six years ago little has been done to increase our knowledge of the complex mixture, spiritus ætheris nitrosi. True, pharmaceutical literature published since then shows that it does not "always contain the same proportion of the same ingredients," and the reason why was very clearly shown in the discussion which followed Mr. Abraham's paper at the Southport meeting of the Pharmaceutical Conference. This paper is not intended to add to our knowledge of the composition; I can only consider it as a preliminary statement of the work which I have been enabled to do in the subject. Without entering, therefore, into the question of the "other compounds," I meanwhile propose to discuss the composition as related to deterioration; that is, the existence in the spirit of ethyl nitrite and aldehyde and the influence they exert in causing deterioration. Taking the official spirit as our standard we find that opinion is fairly agreed as to ethyl nitrite and aldehyde being always present in it. Their presence can very readily be demonstrated, as by the tests which I show you.

Proportion of Ethyl Nitrite in the Spirit.—Were all the nitric acid ordered in the official process reacting with the alcohol *to form only ethyl nitrite* ($C_2H_5NO_2$), we should expect to find somewhat over 6·5 per cent. in the finished spirit; but in practice we find that the theoretical yield is not obtained, and only with extreme care can we obtain a product containing 4 per cent. of ethyl nitrite. There is really no authoritative standard to go upon,—the Pharmacopœia tests being empirical, —but Dr. Dupré, in a paper‡ read before the Society of Public Analysts, stated that spirit containing 3 per cent. of ethyl nitrite fairly represented the B.P. preparation. This percentage is a fair one, and as Dr. Dupré's work has been the "guiding star" of public analysts, we may accept his standard, especially since the experience of practical pharmacists sufficiently justifies it. Mr. Symons having so recently shown (*Pharm. Journ.*, Oct. 13, 1883) the quality of commercial spt. æther. nit., I have not attempted the collection of similar information. It was necessary, however, to determine the amount of ethyl nitrite present as deterioration proceeded, and for this purpose Eykman's method was adopted, others having proved uncertain. It will be seen from the table which I give further on that as high as 3·54 per cent. of ethyl nitrite was found, free nitrous acid not being included in the percentage.

The Aldehyde Content.—Aldehyde has generally been looked upon as an unavoidable contamination, and one of the objects aimed at by Professor Redwood in devising the official process was to minimize the yield of this compound. The percentage of it present in the spirit is variable, and as it is closely associated with ethyl nitrite in deterioration, I shall consider it in the paragraph on *development of acidity*. In the distillate of the Pharmacopœia process I have not found higher than 2 per cent. It may be stated that the method of estimation adopted was that devised by Dr. Thresh,* which is based on the formation of aldehyde resin with excess of caustic soda solution, the coloured solution formed being diluted to the tint of a standard aldehyde resin solution, and compared as in nesslerizing. From 5 to 10 c.c. of the spirit may be used. The method gives fairly constant results, and though they may be approximate, still they are much more constant than those given by Mr. Rimmington's method,† which depends on oxidation of the aldehyde with hydroxyl solution and subsequent titration with standard alkali. The weakness here is that the acidity produced depends on more than aldehyde.

These two bodies, ethyl nitrite and aldehyde, are the leading factors in determining the deterioration of spiritus ætheris nitrosi, another being their solvent, rectified spirit, a mixture of alcohol and water. The decomposition which results in the mixture of these three bodies is attended by at least three marked changes which can be physically and chemically determined:—

1st. Increase of specific gravity.

2nd. Diminution of the volume of ethereal liquid separated by saturated chloride of calcium solution.

3rd. Development of acidity.

The extent of these changes we shall consider in their order.

Increase of Specific Gravity.—In the following table I give results of observations. I. to V. are B.P. spirit made by myself or procured as such. VI. is spirit answering B.P. tests raised to ·850 with water, and VII. is the ·850 of London Pharmacopœia.

	Made.	When examined.	Sp.gr. 50° F.
I.	Not known.	May, 1883.	·848
I.	Not known.	March, 1884.	·853
II.	Not known.	May, 1883.	·852
II.	Not known.	March, 1884.	·8576
III.	Nov., 1883.	March, 1884.	·852
IV.	Received Nov., 1883.	March, 1884.	·8516
V.	Feb. 14, 1884.	Feb. 14, 1884.	·846
"	"	Feb. 21, 1884.	·850
"	"	March 7, 1884.	·8516
VI.	Feb. 15, 1884.	March 7, 1884.	·8536
VII.	Received Nov., 1883.	Feb. 14, 1884.	·856
"	"	March 7, 1884.	·859

Diminution of Separation Volume.—In this I give the result of examination of two specimens of the B.P. spirit kept under different conditions,—α in a well stoppered and almost full bottle, which was opened frequently, and β kept in a badly stoppered bottle, half full, and between the second and third observations the stopper was accidentally left out over a night.

It will be convenient to reserve remarks on these observations until we consider—

The Development of Acidity.—The free acids existing in the spirit are acetic and nitrous acids. It has been stated that nitric acid is also present, but the ordinary methods for determining the existence of nitric acid in presence of the nitrous, are inapplicable in this case. It is questionable, however, if nitric acid can exist as such in presence of the readily oxidizable constituents of the spirit. I have, therefore, calculated the inorganic acid as nitrous acid (HNO_2).

The free acids were determined volumetrically,* semi-normal solution of soda was used, methyl orange being taken to indicate nitrous acid and phenolphthalein to indicate total acidity. The method is certainly not free from objection, the sources of error being (1) decomposition—that is, further acidity—of the spirit during the estimation, and (2) decomposition of the methyl orange by free nitrous acid. The first error can be limited by rapid manipulation, use of undiluted spirit and a small flask. The second is not so rapid in its action as to preclude indication, and by using the methyl orange externally as well as internally, the error is minimized. In the method we take 10 c.c. of the spirit, which is put into a 50 c.c. flask, in which a drop of phenolphthalein has previously been put, then two or three drops of methyl orange solution are put in. Before the estimation is commenced several spots of methyl orange solution are placed on a white plate, and a glass rod should be at hand. The standard solution is quickly, but carefully dropped into the flask, and as soon as the red colour of the methyl orange begins to fade, the glass rod should be dipped in and brought into contact with a methyl orange spot on the plate. If the spot assume a strong pink colour, we have an indication that the nitrous acid is not quite neutralized, so the addition of standard solution is continued until the methyl orange spot becomes but feebly pink. The volume of standard solution used is noted, and the titration continued until the phenolphthalein indicates alkalinity. The first portion used is calculated for nitrous acid and the second for acetic acid.

In the following table the results of several observations are given in percentages, the proportion of ethyl nitrite and aldehyde (as far as determined) being also given. I. to IV. are B.P. spirit (α and β of the separation paragraph are II. and III.); VII. is B.P. raised to ·850, and the others are the ·850 of Lond. Phar.

* In Mr. Rimmington's method the spirit is unduly exposed to atmospheric influence and the action of water.

Having before us these tabulated results of the effect of deterioration on the specific gravity, separation volume, and acidity of the spirit, we may now discuss the causes of decomposition and deterioration.

Ethyl nitrite, it is well known, is a very volatile fluid, and if the spirit be stored in imperfectly closed bottles, considerable loss will result from evaporation. But this does not account for the specific gravity, for since ethyl nitrite is of greater density than spt. æther. nit., the loss by evaporation would tend to decrease rather than increase the density of the spirit. Although Dr. Dupré has stated (see paper quoted) that the acidity of the official spirit is not due to decomposition of ethyl nitrite, yet all pharmacists who have studied this subject have recognized the text-book statement, that the water contained in the rectified spirit used in the preparation reacts with the ethyl nitrite to form alcohol and nitrous acid. A further change takes place, in which acetic acid is one of the products, and since the aqueous solutions of these acids are supernormal, they will tend to increase the specific gravity, and as ethyl nitrite disappears in their formation, the separation volume necessarily decreases. Independent of the reaction between water and ethyl nitrite another reaction takes place, in which acetic acid is formed. What is this reaction? Oxidation of aldehyde, is a natural reply, and to this oxidation the formation has generally been attributed. But it will be observed from the acidity table that aldehyde is an *increasing* rather than *decreasing factor*, as we should in these circumstances expect. This is particularly observable in the case of III., which decomposed rapidly. Without denying that the formation of acetic acid is due in part to oxidation of aldehyde, it must be admitted that another explanation is required. Rapid decomposition is the result of atmospheric influence, and is analogous to the observed fact that the spirit decomposes much more rapidly in partially filled bottles than in full bottles. This observation leads us to infer that part, at least, of the acetic acid is due to oxidation of ethyl nitrite. This oxidation might be expressed in one formula, in which acetic and nitrous acids are formed:—

$$C_2H_5NO_2 + O_2 = HC_2H_3O_2 + HNO_2.$$

We may also express this in two stages; in the first we have aldehyde and nitrous acid formed:—

$$C_2H_5NO_2 + O = C_2H_4O + HNO_2.$$

In the second the aldehyde is oxidized to acetic acid:—

$$C_2H_4O + O = HC_2H_3O_2.$$

It should be further noted that in spite of the greatest care a little nitrous fumes pass over with the distillate in the course of preparation; this admixture, though minute, is sufficient to act as a nucleus, and hence another cause of decomposition under the best conditions for preservation. The effect of water in influencing decomposition is well seen in the case of VII., which contains additional water. The disappearance of acetic acid in the case of I. is probably due to combination between the ethyl radical and it, acetic ether being formed.

Increase in aldehyde may be due to such a reaction as that expressed in the first stage of the formula given, effected either by direct oxidation or by the action of nitrogen acids upon ethyl compounds. An explanation which is not without interest, though purely suggestive, is that it is due to depolymerization of paraldehyde. You are aware that Mr. Williams stated at Southport that he had a strong suspicion that sweet spirit of nitre contains paraldehyde, which he says is formed during the ordinary process adopted in making the spirit. Well, assuming that paraldehyde (boiling at 124° C.) is capable of passing over with the distillate between 70° and 80° C., we would expect that the action of nascent nitrous acid would be to resolve it into aldehyde, and hence an increase. I show you some "pure paraldehyde" which has been so treated and you will notice that the pleasant odour of paraldehyde has been replaced by the pungency of aldehyde, and it gives the aldehyde resin reaction, whereas the untreated paraldehyde does not.* If I have the opportunity of making a further communication on this subject, I shall return to this question of the increase of aldehyde.

In conclusion I may be allowed a few remarks on the relation which these results have to everyday pharmacy. I have been partly led to make this communication from the continually reiterated statement that "spt. æther. nit., B.P., is quite unfit for use," and that "the ·850 spirit keeps much better;" the inference being that the latter is the better preparation. If any proof to the contrary is required we have it in Mr. Symons's paper, in which he gives the result of analysis of six samples of the ·850 article, only two of which indicated over 1 per cent. of ethyl nitrite and two were under 0·4 per cent.,—these percentages including free acid. In the course of this paper results of experiments with the ·850 spirit are given, and it will be seen that it is subject to increase of density and acidification,—of course, this spirit never gives a separation. Now, the arguments used against the official spirit are, 1st, that the public will not have it, and 2nd, that its acidity renders it unfit for dispensing. The first argument is certainly serious looking, but a number of pharmacists tell me that they never have kept anything but the official spirit, and their experience is that after a series of explanations to their customers they will have nothing else, which is a very wise decision on the part of the customers. To discard the spirit on account of the second argument is of course absurd, for we are legally required to use only the official spirit in compounding physicians' prescriptions. Practically, however, the objection is merely one of degree. In the common ·850 spirit, the acidity is less, because the ethyl nitrite content is extremely small; if pharmacists, therefore, prefer to keep this spirit on account of a vague idea that it is a "better keeping" one, they assume a very serious responsibility. The proportion of ethyl nitrite in the official spirit might no doubt be judiciously decreased and fixed, but even though it were fixed at 2 per cent., it is evident that the objection would only be lessened and not removed. It is, therefore, left to the pharmacist to control deterioration by careful storage of his stock. Hydrocyanic acid is kept in small phials, so that *it* may not deteriorate; so might we keep spt. æther. nit. in proportionately smaller bottles than at present, with equal care. The shop round need not be of the largest series or nearest the shop window, and stored stock should certainly not be kept in partially filled Winchesters, nor need we lay in a stock which will serve the better part of the solar year.

* On this point see abstract of article by A. P. N. Franchimont, *Journ. Chem. Soc.*, xliv., 453.

For the purposes of this investigation, Messrs. J. F. Macfarlan and Co. have liberally supplied me with spt. æther. nit., B.P., and other material, for which I desire to thank them. My thanks are also due to Mr. Dott for much technical information.

[*The discussion on this and the following paper is printed at p.* 825.]

SPIRIT OF NITROUS ETHER.*

BY D. B. DOTT, F.R.S.E.

In this paper on sweet spirit of nitre I have no intention of taking up the slippery subject of its composition and transformations, which Mr. MacEwan has been bold enough to tackle; but am only desirous of discussing the characters and tests of this important preparation. Before doing so, however, it is necessary to refer briefly to what is known of its composition, in order that we may decide what tests it ought to answer. To fix exactly the composition of sweet spirit of nitre is doubtless a problem beyond the attainments of chemical analysis, but there is no reason why we should not have a better knowledge of its chemistry than we at present possess. We may safely say that ethyl nitrite, acetic aldehyde, nitrous and acetic acids, and ethyl acetate, are normal constituents of spiritus ætheris nitrosi. It has been almost universally recognized that the value of the preparation depends on the presence of the nitrite, though this has been doubted by a few writers. Among these is Mr. Abraham, of Liverpool, who believes the aldehyde to be the active ingredient. According to this view the aldehyde is oxidized to acetic acid, which forms acetates with the alkalies of the blood, whereupon the physiological effects are manifested. If I rightly follow this train of reasoning, it would appear that one may as well swallow a little vinegar as take a dose of sweet spirit of nitre. Not being a pharmacologist, I wrote to Professor Matthew Hay, of Aberdeen, on the matter, and have received from him a very interesting letter, from which I cannot do better than quote a few sentences.

"With regard to aldehyde, I cannot at the present moment recall having seen any notice of its physiogical action. I rather think it has not to any extent been investigated. But although that is probably so, I am fairly certain, judging from its chemical relationship to alcohol and the ethers, that in action it will differ to no great extent from these."

"With regard to the sweet spirit of nitre, my opinion is this, that its most active ingredient ought to be the nitrite of ethyl, which it is believed to contain, to, I think, the extent of 2 per cent. But so far as my observation carries me, nitrite of ethyl is present in very variable quantity in the ordinary spirit of nitrous ether, and is sometimes hardly to be detected at all. The nitrite is very active even in very small quantity; and, I believe that if a preparation of spirit. æth. nit. could be obtained containing a constant proportion of nitrite of ethyl, it would be a great gain to practical pharmacy and to therapeutics. The unreliability of the common forms of it has, I believe, led largely in recent years to its disuse."

"Murrell states that nitroglycerine is powerfully diuretic, and I have shown that nitroglycerine is

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, March 19, 1884.

decomposed into nitrite in blood, hence its physiological action—hence diuresis."

I am glad to have my own opinion confirmed by so eminent an authority. We may, therefore, conclude that the right means of estimating a sample of spirits of nitre is to determine the amount of nitrous ether, or rather, of nitrous acid, which it contains. I am far from denying that the medicinal value of the spirit may be materially enhanced by the aldehyde and acetic ether, but these must be regarded as quite subordinate. Besides, it is difficult to estimate their amount.

Let us now consider, one by one, the tests of the British Pharmacopœia. Firstly, we have the specific gravity, which is given as ·845, at 60° F. This is really only a safeguard against admixture with water, though there is a delusion, still to some extent prevalent, that the ·850 must be a better article than the ·845. Doubtless this has arisen from the fact that nitrous ether has a greater density than rectified spirit. It has therefore been supposed that a preparation rich in nitrous ether will have a high specific gravity, but this is a mistake; for it is easy to prepare a spirit fully up to the Pharmacopœia requirements with a specific gravity even less than ·845. According to our experience a high specific gravity just means so much the more water, and if one fact regarding spirit of nitre has been proved more conclusively than another, it is, that water encourages the decomposition of the ether. Whence it is manifest that the specific gravity ought to be kept as low as possible consistent with the due proportion of ethyl nitrite.

Secondly, "it effervesces feebly or not at all when shaken with a little bicarbonate of potash." Not much can be said against this test, though it is perhaps a little indefinite. It might be better to have a limit fixed to the amount of free acid, the same to be determined by standard alkali—but this is doubtful.

Thirdly, "if it be agitated with twice its volume of saturated solution of chloride of calcium in a closed tube, 2 per cent. of its original volume will separate in the form of nitrous ether and rise to the surface of the mixture." This test has given rise to much controversy. It belongs to the class of inaccurate empirical tests, which are always unsatisfactory, though sometimes tolerable when nothing better can be obtained. Chemists have all recognized that the "ethereal fluid," which separates under the above circumstances, is not ethyl nitrite, but a solution of the same, of variable strength. It is probably just as well that it is so, especially when the testing is performed on a warm summer day. Judging from some estimations which I made by the method subsequently described, this etheric fluid would seem to contain from 50 per cent. to 60 per cent. of nitrous ether. Professor Attfield* says that it contains less than half its bulk of ethyl nitrite. Professor Redwood† is responsible for the generally accepted belief that 2 per cent. of separation indicates 10 per cent. of ether. If made regarding the "ethereal fluid," which actually separates, the statement may be fairly correct, but it is quite untrue if applied to a 10 per cent. solution of ethyl nitrite in spirit. Such a solution will separate more than half its contained ether when agitated with solution of calcium chloride. I have tried many experiments with this test, but it would be superfluous to detail them. Suffice it to say that there are three main factors which determine the amount separated:—

1st. The composition of the spirit.

2nd. The temperature.

3rd. The dimensions of the tube.

Regarding the first of these I would only remark that if the spirit is watery it will give a better result, *cæteris paribus*, than one containing less water. It will readily be understood that with a compound having so low a boiling point, and so high a vapour pressure at ordinary temperatures as nitrous ether, the proportion separated by chloride of calcium solution must be much affected by the second and third of these causes; *e.g.*, 15 c.c. of spiritus ætheris nitrosi at 48° F., shaken up with two vols. solution of calcic chloride at same temp., gave a separation of 0·4 c.c. When the experiment was repeated with the spiritus and chloride solution at the temp. of 68° F., separation of only 0·2 c.c. was obtained. By using a capacious tube in one case, and in another a small tube which the mixture nearly filled, results almost as variable were observed. It may here be noted that the "ethereal fluid" takes some time to separate, the process being seldom complete in less than half an hour. The greatest objection to this test is, however, the well-known fact that a genuine preparation will after a certain time, and while still retaining its medicinal virtues, fail to give any separated "ether" when agitated with solution of chloride of calcium. Taking all the facts into consideration, I am clearly of opinion that this separation test ought to be abolished.

What we require is a test which shall show at least approximately the value of the preparation, by means of reagents and apparatus at the disposal of every pharmacist. This must be done by estimating the nitrous acid, whether it exists as such or potentially. There does not appear to be any reason for making a separate determination of the percentage of uncombined nitrous acid, which no doubt contributes its share to the physiological action of the substance. Of the many methods which have been proposed for the purpose of this estimation, probably the best is that devised by Professor Eykman, of Tokio. Not that I regard his process as perfect, because I believe it gives results distinctly under the truth, and of course it includes the nitric acid should any be present. The fatal objection to Eykman's process as a pharmacopœial test is the elaborate apparatus and nicety of manipulation required. It is, in short, better adapted for the laboratory of the analyst than for the pharmacy; and as all the official tests ought to be as simple as possible, we must endeavour to find an easier method. I have tried a great number of experiments with this object, and have to confess that the result after all is not a complete success. The old method of saponifying with caustic soda, and after evaporation of the alcohol, titrating with permanganate, was found to yield very variable results. This is not surprising considering the facility with which potassic permanganate is reduced, and the certainty that there are organic compounds present after evaporation even to dryness. Oxidation of ferrous sulphate was next tried, but from the difficulty of estimating the excess of ferrous salt in the presence of alcohol, and from other causes, the process proved abortive. Volumetric solution of urea was then

* *Pharm. Journ.*, [3], viii., 378.
† *Pharm. Journ.*, [2], viii., 508.

employed, iodized starch solution being used to indicate the end of the reaction, but this plan proved entirely unsuccessful, chiefly on account of the impossibility of observing a definite end-point. Possibly, however, the urea method might be made available by measuring the N, or weighing the CO_2 evolved; that is to say if the reaction goes as it ought. $CON_2H_4 + 2HNO_2 = CO_2 + N_4 + 3H_2O$.

The nitrous ether might possibly be estimated by reduction with hydric sulphide, but I have not had time to thoroughly examine this reaction. The few experiments I have been able to perform with it did not yield promising results.

After innumerable experiments I have been compelled to return to the method which suggested itself to me first of all, viz., the liberation of iodine from potassic iodide, and titration of the iodine with sodium thiosulphate. The only mention I have seen of the use of potassium iodide as a means of estimating spiritus ætheris nitrosi, is reported in the *Pharmaceutical Journal.** In the discussion after the reading of Dr. Dupré's paper, Mr. Hehner suggested the use of iodide of potassium added directly, with addition of acetic acid, which was thought a good idea. The process is so obvious, that it has probably often been tried and abandoned, which would not be surprising, as without particular precautions it yields results which have no resemblance to the truth. In endeavouring to put this test into practical form, I very soon found that the only way of arriving at right results was to work with a solution of ethyl nitrite of known strength; at least in the first place. We therefore purified some of the nitrite by a method similar to that described by Mr. Williams.† At 60° F. it had a specific gravity of ·901 (or thereby). Mr. Willliams gives the gravity as ·937, but states no temperature. At all events, though it was not analysed, I am confident that it must have been very nearly pure. Ten c.c. were diluted to 100 c.c. with "absolute" alcohol, and this solution was used in the following experiments.

(1). 5 c.c. = 0·45 gram $C_2H_5NO_2$ added to an aqueous solution of 20 grs. potassium iodide, 1 drm. dilute sulphuric acid then mixed therewith, and after half an hour standard thiosulphate run in. Required 28·0 c.c. = 0·21 gram $C_2H_5NO_2$. This low result was caused by loss of ether, which is thrown to the surface of the saline solution. It is hence evident that some solvent must be used to retain the ether.

(2). In this case the same quantities were used, but before the addition of the ethereal solution, 1 fl. oz. rectified spirit was mixed in. The solution was allowed to stand ten minutes before running in the thiosulphate. Required 113·5 c.c. = 0·851 gram $C_2H_5NO_2$. This high indication was caused by the nitric oxide which must be completely removed before the titration. It is essential that the NO be got rid of not only from the alcoholic solution but also from the atmosphere in the containing vessel, as otherwise by uniting with the oxygen to form higher oxides, and these in turn reacting with the water to form nitrous acid, an additional quantity of iodine is liberated. Using the same proportions as just mentioned, but employing a large flask and diligently agitating during the addition of the thiosulphate solution, nearly 300 c.c. were used before decolorizing.

* [3], x., 93.
† *Pharm. Journ.*, [3], viii., 442.

(3). In this experiment the same quantities were used as in (2) but acetic acid instead of sulphuric, the solution being allowed to stand one hour. Required of thiosulphate 21·6 c.c. = 0·162 gram $C_2H_5NO_2$, which is far too low. Acetic acid, as suggested by Hehner, will, therefore, not do.

(4). Several experiments were tried, passing carbonic anhydride into the test solution contained in a flask. The gas was passed in before addition of the acid, and the stream continued until the completion of the titration. In other cases the CO_2 was passed only into the air space above the liquid. In all these instances the results obtained were too low and very variable, possibly on account of the gas carrying away some of the ether.

It would be tedious to describe the different devices that have been tried, to ensure, if possible, an accurate result. Suffice it to say, that as an inference from numerous experiments, the following method was adopted as the best:—Let 1 gram of iodide of potassium be dissolved in 10 c.c. of water. Then add 20 c.c. of rectified spirit, and to the solution so obtained add 5 c.c. of the spirit to be tested. Now pour in 5 c.c. dilute sulphuric acid, and allow to stand for an hour, then titrate with standard thiosulphate.

The operation is best conducted in an eight ounce porcelain basin. The following are some of the results obtained:—

(5 *c.c. used in each case.*)	$\frac{1}{10}$ $Na_2S_2O_3$ solution.		$EtNO_2$ grams.		$EtNO_2$ (vol.) per cent.
(*a.*) 10 per cent. (vol.) soultion in alcohol	59·5 c.c.	=	·446	=	9·91
(*a.*) 10 per cent. (vol.) solution in alcohol	59.8 c.c.	=	·448	=	9·96
(*a.*) 10 per cent. (vol.) solution in alcohol	60·0 c.c.	=	·450	=	10·00
(*b.*) Sple. sp. æth. nit. (recent)	26·5 c.c.	=	·198	=	4·41
(*b.*) Sple. sp. æth. nit. (recent)	26·8 c.c.	=	·201	=	4·46
(*c.*) Sple. sp. æth. nit. (four months)	23·5 c.c.	=	·176	=	3·91
(*c.*) Sple. sp. æth. nit. (four months)	24·0 c.c.	=	·180	=	4·00

Although formerly indicated, it may again be noted that the total nitrous acid is given as ethyl nitrite. The older sample contained much more free acid than the fresh one. The method employed is evidently only approximate, but it may serve until something better is devised. It has, at any rate, the advantage of requiring only such apparatus and reagents as are in common use.

Before concluding, I would venture to express a hope that the compilers of the next Pharmacopœia will fix a fair standard of purity for spirit of nitrous ether, so that no departure therefrom will be allowed. We sometimes hear the fallacy propounded, that an inferior preparation must be excused, because, at some time or other, it has been produced by the official process. This is an entire mistake. Not only must the official process be followed, but it must be so conducted as to produce a right result, and the product must be so preserved as to be of proper strength when required for use. Yet, as the Pharmacopœia requires of pharmacists preparations of a certain degree of purity, so pharmacists require of the Pharmacopœia processes and tests which are reasonable.

THAPSIA RESIN.*

BY F. CANZONERI.

The root of *Thapsia Garganica*, a plant known for its vesicating properties, yields to boiling alcohol a white amorphous waxy substance, slightly soluble in ether and carbon bisulphide, and melting, after purification, at 90°. This substance, however, forms but a small part of the thapsia root. More abundant and important constituents are obtained by treating the dried and chopped root in a percolator with ether, whereby a yellow solution is obtained, which, on distilling off the ether, yields an amber-coloured syrupy resin possessing strong vesicating properties. This acid dissolves in strong aqueous potash at ordinary temperatures and in dilute potash when heated—in both cases with great rise of temperature,—and on neutralizing the resulting solution with hydrochloric acid, a yellow curdy precipitate is formed, having an unpleasant odour, and consisting of a mixture of liquid and solid ethers and fatty acids, together with resinous substances. From this mixture of products, the author has obtained: (1.) An octoic or caprylic acid, $C_8H_{16}O_2$; (2) a new acid of the series $C_nH_{2n-2}O_4$, which he designates as thapsic acid; (3) a non-azotized neutral vesicating substance.

This last constituent was obtained in very small quantity only, and in some preparations was altogether absent; it is moreover very difficult to purify from resinous substances and wax, by which it is generally accompanied. It dissolves in hot alcohol, and separates on cooling in shining needles melting at 87°; also in ether and in carbon bisulphide; all its solutions possess vesicating properties. Heated with strong potash-lye, it dissolves partially and is precipitated in the crystalline state on diluting the solution with water. It is not altered by boiling with strong acids. Heated on platinum foil, it burns away without residue, emitting a pleasant odour.

Thapsic acid, $C_{16}H_{30}O_4$, is obtained by pressing between paper the curdy precipitate formed on adding hydrochloric acid to the solution of the resin in aqueous potash, and crystallizing it several times from boiling alcohol with addition of animal charcoal. It forms white shining scales melting at 123° to 124°, nearly insoluble in water, benzene, and carbon bisulphide, soluble in alcohol, less soluble in ether. When strongly heated, it distils without alteration; ignited on platinum foil, it burns with an odour of burnt wax. It is but slowly attacked by bromine or by strong nitric acid. It is a bibasic acid. Its *potassium salt*, $C_{16}H_{28}O_4K_2$, forms shining anhydrous prisms. The *barium salt*, $C_{16}H_{28}O_4Ba$, obtained by precipitation from the potassium salt, is a white amorphous powder insoluble in water and very slightly soluble in boiling alcohol. The *silver salt*, $C_{16}H_{28}O_4Ag_2$, is a white insoluble precipitate which blackens when heated or exposed to light.

Thapsic acid dissolves at boiling heat in aqueous ammonia, and the solution on cooling deposits a crystalline substance probably consisting of the corresponding amide. The acid heated with aniline at 170° to 180° in sealed tubes, is converted into the anilide,

$$C_{16}H_{28}O_2(NHPhen)_2,$$

which forms a white crystalline powder melting at 162° to 163°, and acquiring a faint violet colour when exposed to the air.

The barium salt of thapsic acid distilled at a moderate heat with excess of barium hydroxide, yields a small quantity of hydrocarbons, saturated and non-saturated, having a musky odour, combining for the greater part with bromine, and forming a solid body which, when dried between bibulous paper and crystallized from alcohol, forms white needles melting at 73°.

Octoic or Caprylic Acid, $C_8H_{16}O_2$.—On distilling with steam the oily precipitate obtained by neutralizing with hydrochloric acid the potash-solution of the ethereal extract of the resin, after removal of potassium thapsate and dilution with water, there passes over a yellow transparent oil, lighter than water. On exhausting this oil with ether, drying the etheric solution with calcium chloride and distilling, the greater part goes over at 220° to 236°; and on fractioning this portion at intervals of 5°, three other fractions are obtained, the most abundant of which is a colourless liquid soluble in alcohol and ether, and solidifying when cooled with snow, in flexible laminæ melting at ordinary temperatures. The product thus obtained is shown by analysis to have the composition of an octoic acid, and in its melting and boiling points it agrees nearly with the octoic acid obtained by saponification of cocoanut oil, and by oxidation of the octyl alcohol from heracleum oil, melting at 16°, boiling at 236° to 237°, which agreement the author has further confirmed by examination of the sodium, barium and zinc salts.*

The author suggests that thapsic acid may be a *dioctoic acid*, $C_8H_{15}O_2.C_8H_{15}O_2 = 2C_8H_{16}O_2 - H_2$, formed from the octoic acid by slow oxidation in the body of the plant.

* From the *Gazzetta*, xiii., 514-521. Reprinted from the *Journal of the Chemical Society*, April, 1884.

* The author, in accordance with the view hitherto generally entertained, regards this acid as normal octoic acid, $CH_3(CH_2)_6COOH$, but recent investigations have shown that the primary octyl alcohol of heracleum oil is an iso-alcohol, $CHMe_2(CH_2)_4.CH_2OH$, and consequently that the acid obtained from it by oxidation must be an iso-acid, $CHMe_2(CH_2)_4.COOH$. (See Watts's 'Dictionary of Chemistry,' viii., 379.)

SPARTEINE.†

BY O. BERNHEIMER.

This base, $C_{15}H_{26}N_2$, was first obtained from *Spartium scoparium* by Stenhouse in 1881, who determined its composition, and was afterwards examined by Mills, who showed that it is a tertiary diamine. The sparteine examined by the author was prepared from *Spartium scoparium* by a slight modification of Stenhouse's method; it distilled to the last drop at 180-181° under a pressure of 20 mm. Its solution in alcohol at 96° has a specific rotatory power $[\alpha]_D = -14{\cdot}6$ for a concentration of 23·88 at 26°. It bears a heat of 200° without alteration, but becomes partially carbonized at higher temperatures; is not decomposed by heating in sealed tubes with hydrochloric acid. Bromine acts strongly on sparteine at ordinary temperatures, even when it is largely diluted with ether forming an undefined resinous mass.

On gradually adding 3 parts iodine dissolved in ether to an etheric solution of 1 part sparteine, the iodine is decolorized, and a black precipitate is formed, which when separated, washed with ether to remove free iodine, and dissolved in boiling alcohol, separates on cooling in beautiful green needles, having the composition $C_{15}H_{26}N_2I_3$. This compound is insoluble in cold water and alcohol, but dissolves readily in those liquids when heated; it is insoluble in ether, permanent in the air, and yields free sparteine when heated with potash.

Sparteine (as sulphate) oxidized with potassium permanganate yields a small quantity of a volatile acid, having the odour of the fatty acids, together with non-volatile acid having the composition of a *pyridinemonocarboxylic acid*, $C_5H_4N.COOH$; and on distilling a salt of this acid with lime, a volatile base is obtained having all the properties of pyridine. The author intends to continue his experiments as soon as he is in possession of a larger quantity of material.

† Preliminary notice. From *Gazzetta*, xiii., 451-454. Reprinted from the *Journal of the Chemical Society*, March, 1884.

The Pharmaceutical Journal.

SATURDAY, APRIL 12, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PETER SQUIRE.

WHEN Death comes to some men to whom it is given to serve their fellows he overtakes them still busy, with their work uncompleted; others having finished their labour are found so entirely forgotten in their retirement that the news that they have passed away hardly excites more surprise than the discovery that they were alive so recently. But it was not so with PETER SQUIRE, whose death it is our painful duty to record this week. Although bearing the ripe burden of eighty-six years when he died, his name is still familiar as a household word among pharmacists, through the admirable *vade mecum* which he placed at their disposal and which he continued to supervise almost to the last, whilst three years have not elapsed since he took part in the discussions at the Fifth International Pharmaceutical Congress, of which he was elected a Vice-President, and contributed an able paper upon a subject that he had made his own, the equalization of the strength of preparations of potent drugs in the different pharmacopœias. Indeed it is difficult to realize that one who was so recently a real living influence among us could have been the colleague and contemporary of men who have receded so far into the past as WILLIAM ALLEN, RICHARD BATTLEY, JACOB BELL, CHARLES DINNEFORD, DANIEL BELL HANBURY, WILLIAM INCE, THOMAS MORSON, CHARLES JAMES PAYNE, JONATHAN PEREIRA, JOHN SAVORY, and many others that might be named. Keen of intellect, vigorous of habit, indefatigable in work, pungent in speech, a thoroughly capable business man and yet a pharmacist who has left his mark on both the practical and scientific aspects of his calling, PETER SQUIRE was a man of whom British pharmacists may well be proud; for it can hardly be hoped that they will more than occasionally be able to boast of men who are his equals.

Like many men who prove themselves eminently capable of looking after their own interest, and probably because they are so, Mr. SQUIRE found time to render signal services to others. As early as the year 1841 he joined in the struggle to place pharmacy on a proper footing in this country, having been a member of the sub-committee entrusted with the task of opposing the progress of the Bill of Mr. HAWES in Parliament, and which eventually drew up the proposition for the perpetuation of the temporary organization in the interests of chemists and druggists that resulted in the formation of the Pharmaceutical Society of Great Britain. As a member of this Committee, Mr. SQUIRE became a member of the Council of the newly-fledged Society. Afterwards when it was determined to carry out that part of the programme which associated examination with membership, and other bodies to which the Council was at first disposed to look for help in this direction declined to render it, his colleagues found in him an invaluable organizer of the first Board of Examiners. During twenty-seven years he was himself an active member of that Board, and when he retired from it in 1869 his colleagues placed on record their high appreciation of his valuable services in an address which they presented to him. Meanwhile he had been chosen in 1849 to preside over the Society he had assisted in forming, an honour that was repeated in 1861 and and in 1862, and during this latter term of office he took an active part in conjunction with the Secretary, Mr. ELIAS BREMRIDGE, in securing the insertion in a Juries Bill before Parliament of a provision for the exemption of pharmaceutical chemists from service. Mr. SQUIRE continued a member of the Council until 1870, when he declined further nomination, having helped to conduct the affairs of the Society during nearly thirty years.

Mr. SQUIRE's services to pharmacy were, however, by no means confined to the business of the Pharmaceutical Society. His studies of the juices of plants had already before its formation practically rewritten the formulæ for extracts, and his success as a practical pharmacist had won for him the appointment of Chemist to the Queen. Much other valuable work, more or less scientific, was done by him, but perhaps some of the most lasting in its influence was that connected with compilation and publication in 1851 of the comparison of the three Pharmacopœias then official in the three kingdoms, which paved the way for and rendered inevitable the British Pharmacopœia. Other publications of Mr. SQUIRE are too well known to mention here, and, probably whilst adding to his reputation they yielded him satisfactory returns of another kind. Throughout his life, from boyhood to old age, PETER SQUIRE was active, persevering, industrious, and self-reliant. Whilst some of his characteristics were too marked to allow him always to escape criticism, yet if his opponents had survived instead of preceded him, as most of them have done, they would have been among the first to proclaim that in PETER SQUIRE pharmacy has lost a sterling man.

ALCOHOLIC FERMENTS.

THE capability of saccharine juices obtained by expression from fruits, such as grapes and apples, to undergo the change now known as alcoholic fermentation was evidently familiar to the human race in the earliest historic periods, but it has been only in recent years that clear glimpses have been obtained of the nature of the phenomena involved. Even now, although it is generally well understood that alcoholic fermentation is a physiological function of certain species of fungi, there remains considerable obscurity about the life history of these organisms. The presence on the surface of ripe fruit of germs capable of inducing fermentation in the juice of the fruit was first demonstrated by M. PASTEUR, but even this able investigator was obliged to leave the source of the germs unexplained. Different observers have shown that these particular kinds of germs are frequently present suspended in atmospheric air, but not in sufficient quantity to explain the abundance in which they occur on the surface of fruits. Moreover, M. PASTEUR noticed that the germs are not found on the skin of the grape until it ripens, so that it is only during a comparatively short portion of the exposure of the fruit to atmospheric influences that the skin becomes coated with the fermentative particles. It is evident, therefore, that in order to understand the manner in which the ferment is perpetuated from one vintage to another, some clue as its habitats at different periods of the year was necessary, and an important contribution towards the elucidation of this point was made two or three years since by a Danish botanist, Dr. HANSEN, in the observation that the soil is the winter resting-place of the spores of *Saccharomyces apiculatus*. Following up this line of investigation a French worker, M. BOUTROUX, has discovered other natural habitats of the alcoholic ferments in flowers and insects, but for the most part the species of ferments observed were new ones. Although the interesting account of his work which has been recently published in the *Annales des Sciences Naturelles* cannot be said by any means to have settled the question as to the hibernation of the most important of the ferments, it is suggestive of a field of research that is at present almost unexplored.

The course of investigation adopted by M. BOUTROUX was to test various substances as to whether they were acting as carriers of ferment germs by placing them in a previously sterilized fermentescible liquid, under conditions favourable to fermentation. If any evolution of gas resulted the organisms present were examined under the microscope, and in the event of any being detected that appeared to be alcoholic ferments they were isolated by successive cultivations in media favourable to their propagation and unfavourable to the development of other organisms by which they might be accompanied. A slightly acid medium was found preferable as preventing the development of bacteria; grape must proved extremely suitable, as might be expected, and cherry juice diluted with water was also used successfully. In this way the experimenter determined the presence of alcoholic ferment germs in the nectaries of a considerable number of flowers; they were found at all times of the year, being simply less numerous in winter than in summer, and the conclusion arrived at was that the occurrence of such germs upon flowers is not accidental, but a normal condition. Thus even in winter the germs were present on such flowers as *Petasites vulgaris* and *Erica mediterranea*, and as the weather became warmer the number of ferment-bearing flowers increased, so that in May, every single flower of a plant much frequented by bees, like borage, proved capable of setting up alcoholic fermentation in cherry juice. That the presence of these germs on the flowers was not due to accidental deposition from the atmosphere was inferred from the fact that unripe fruits, taken at the same time from the same plants as the active flowers, were incapable of setting up alcoholic fermentation, whilst even ripe fruits appeared very variable in their behaviour. In fact, a point affecting the presence of ferment germs more than the maturity of the fruit is the condition, for whilst perfectly sound ripe fruits, even grapes, seemed to be practically devoid of germs, the slightest insect puncture or other damage was found coincident with a comparative abundance of them. The question therefore arose whether any connection could be traced between insects as germ carriers and the plants they visited as germ bearers. A number of insects, including bees, wasps, flies, and some small coleoptera, were therefore subjected to a treatment similar to that applied to the flowers. The result was to show that as a rule the ferment germs were more numerous upon the bodies of the insects than upon fruits or even flowers, and it was thought that this fact tended to show that the ferment germs are sown upon fruit by insects who bring them either from other fruits or from flowers that they visit. To prove this theory it was necessary to show that the ferments found upon the insects were of the same kind as those occurring on the flowers; but before this could be done, it was necessary to isolate and define the growths of the different species of *Saccharomyces*, the result being that no less than nineteen kinds of growths were found, presenting different characters and possibly representing different species, but all capable of provoking alcoholic fermentation in saccharine liquids. In connection with this long and tedious portion of the investigation many interesting observations were made, but it must suffice to mention here that it was found that the nineteen kinds were divisible into two groups,—fifteen of them being capable of provoking alcoholic fermentation in a solution of cane sugar as well as of glucose, and therefore called "inversive," while four were capable of provoking it only in solution of sugar already inverted, and were therefore termed "non-inversive."

Having thus prepared the way for ascertaining the relations existing between the ferment germs found in different situations, M. BOUTROUX proceeded with his observations in this direction, but it must be confessed that the results, so far as they are recorded, are far from being decisive. A tabular analysis shows that flowers yielded four inversive and two non-inversive varieties, four of which, two inversive and two non-inversive, were also obtained from immature fruits. Intact ripe fruits yielded no inversive germs, but only the same two non-inversive varieties that were obtained from flowers and green fruits. In damaged ripe fruits, however, one of these disappeared and in its place was another non-inversive ferment, *Saccharomyces apiculatus*, not observed on other fruits or flowers. From insects all the kinds previously referred to were obtained, and therefore the connection between flowers, fruits and insects as alcoholic germ carriers appears to be so far established. But, unfortunately, none of the ferments actually discovered was of primary importance in regard to those cases in which fermentation is carried out economically, and therefore no connection was established between the germs found on flowers and insects and the organisms that are characteristic of the wine, beer, or cider fermentations. The possibility is not excluded that the explanation of this may lie in some of the forms treated as different by M. BOUTROUX being really modifications of the same organism induced by surrounding conditions; though it is candidly admitted that no tendency to such modification was noticed during the experiments. It may be, that the failure to find these economic germs on flowers or insects is due to their extreme rarity, for there appears to be no relation between their ordinary number and their abundance when they find a favourable *nidus* for their development. Thus in a sample of grape must, in which the *Saccharomyces ellipsoideus* was so rare as not to be detected immediately after the crushing of the fruit, it multiplied so rapidly that in two or three hours it was plentiful and very soon crowded out all the other ferments that were originally present. Notwithstanding, however, the apparently imperfect evidence, M. BOUTROUX feels that his results warrant him in putting forward a theory respecting the manner in which the alcoholic ferments are preserved from year to year. In the autumn the germs occur everywhere on ripe damaged fruits, where they multiply rapidly. After the fruit season, they are preserved partly, as shown by M. PASTEUR and M. CHAMBERLAND, on the surviving *débris* of the fruit, and partly, as shown by Dr. HANSEN, in the earth, and thus they pass through the winter. At the commencement of the spring, or even earlier, the germs still surviving are borne by insects to the nectaries of flowers, where they multiply to a certain extent, and during the summer they are cultivated in a succession of flower-nectaries, thanks to the incessant re-sowing carried on through the same agency. Then, in the autumn they are transported by the untiring carriers to the ripe fruit, and the cycle is complete.

We are requested to say that, in consequence of the examinations occurring during the present week in the Society's rooms in Edinburgh, it was found impracticable to hold the Evening Meeting of the North British Branch announced for the 9th inst. It is thought probable, too, that in the following weeks the Tercentenary University festivities would constitute a disturbing influence. It has, therefore, been decided to abandon the meeting, and Dr. Macfarlane has promised to read his paper in the course of next session.

* * *

It is satisfactory to find, from a letter on another page, that the decision of the Council to acquire more important premises in Edinburgh for the housing of the North British Branch is appreciated so far north as Aberdeen. It is hardly for us to decide whether the suggestion made by our correspondent as to the furnishing of the new premises is worthy of carrying out; but we may venture to say that a still better way would be for every Scotch member or associate who desires to show his approval of the liberal policy of the Council to take every opportunity to promote the fuller representation of the Society in the North.

* * *

A circular has been issued stating that pending the rebuilding of the works of Messrs. Powers and Weightman, of Philadelphia, destroyed in the late disastrous fire, an arrangement has been made with Mr. BÖHRINGER by this firm for the manufacture of their quinine in Europe. It appears, however, to be thought not unlikely that, in view of the disadvantages attending the home manufacture of quinine in the United States since the abolition of the import duty, this arrangement may have a somewhat more permanent character than is conveyed in the announcement.

* * *

We have received a copy of the Twenty-Seventh Annual Report presented at the meeting of the Pharmaceutical Society of Victoria on the 12th ult., from which we learn that the progress of the Society during the past year was, in all respects, satisfactory. Allusion is made to the proposal to hold a conference of pharmacists representing the different Australian colonies, which, however, was not carried out in consequence of the refusal of the Pharmaceutical Society of New South Wales to participate in it at present. Another subject prominently alluded to in the Report is the formation of a Chemists' Assistants' Association, having for its object the shortening of the hours of labour. A general meeting of chemists and druggists was called and the proposal put forward by this Association was that shops should be closed on week-day evenings from Monday to Friday at nine o'clock, and on Saturday at ten. This was not accepted by all the employers, and, indeed, was not unanimously supported by the assistants; consequently no general agreement was arrived at. But we are glad to notice that the question is being more satisfactorily dealt with in some districts. The School of Pharmacy is said to have shown a large increase of students, some of whom came from the other colonies. The finances also seem to be in a good condition, the least satisfactory feature in the balance sheet being a considerable loss entailed in the supply of a journal to the members of the Society.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

EVENING MEETING.

(*Concluded from p. 790.*)

The next papers read were on—

SPIRITUS ÆTHERIS NITROSI: COMPOSITION IN RELATION TO DETERIORATION.

BY PETER MACEWAN,

and

SPIRIT OF NITROUS ETHER: ITS CHARACTERS AND TESTS.

BY D. B. DOTT, F.R.S.E.

The papers are printed on pp. 817 and 819, and gave rise to the following discussion:—

Dr. Inglis Clark proposed a vote of thanks to the authors of these papers, and remarked that it was not possible for him to enter into any detailed criticism without the text of the papers before him. Mr. MacEwan had mentioned that acetic acid had decreased, and probably had entered into combination. The decrease was only noted in one specimen, and if it had gone to form acetic ether he would expect that the separation volume would increase rather than diminish. Probably, therefore, the acid had evaporated. Regarding the increase in specific gravity, he thought that this might be the result of contraction caused by loss of the more volatile constituents. Mr. Dott's assay process seemed to give fair results, and its simplicity was in its favour. The high results which he obtained contrasted very markedly with those given by Mr. MacEwan, being over 7 per cent. in the one case and 3·5 per cent. in the other; he would infer from that either that Mr. Dott's specimen was exceedingly good, or that one of the processes was bad. He had listened to the papers with pleasure, and he considered them able contributions to the literature of the subject.

Mr. Gilmour said that he had always considered the official tests unsatisfactory, and he was glad that the papers read were directed to show why that was so. He hoped that better tests would be adopted in the next pharmacopœia. The opinion that the ·850 spirit was better than the official one was pretty widely spread, and it would take a great deal to convince many people that it was not; but it had been very clearly shown that any superior properties which it possessed were due rather to weakness in the proportion of nitrous ether than to superior method of preparation. Mr. Dott's method was very simple and he hoped to give it a good trial after the paper was published.

Mr. MacEwan said that the sample in which acetic acid had decreased so much was at least a year old, and ten months had elapsed between the two estimations. He thought that prolonged contact between the acetic acid and alcohol or other ethyl compound would tend to cause formation of acetic ether. The quantity of this sample at his disposal was not sufficient for the separation test at the time of the second examination, but it gave no separation when first examined. If the method proposed by Mr. Dott gave constant results, or nearly so, he would say that no little difficulty had been overcome, for the continued action of the nitrous fumes on the potassium iodide in the initial stage and during titration seemed an insurmountable difficulty, and had caused him to abandon the process. Judging from the results which Mr. Dott had got with a standard solution of ethyl nitrite he thought that the method promised well. The difference between Mr. Dott's percentages and his own was certainly remarkable, but then the specimens were different. He had used Eykman's process and had taken it upon its merits, for it gave constant results, and this could not be said of any method previously suggested. He had of course deducted from the percentage of ethyl nitrite found by that process the amount of nitrous acid previously determined.

Mr. Dott said he did not say that the method suggested was absolutely correct, but he thought that it gave approximate results, and when thoroughly tried it would be found simple. Of course it should not be forgotten that spirit of nitre was not a pure solution of nitrous ether, so that the other compounds present might influence the test.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council was held on Wednesday, the 2nd inst.

Present—The President, Mr. James E. Brunker, M.A., in the chair; Messrs. Allen, J. Evans, Grindley, Hayes, Dr. Montgomery, Sir George Owens, Mr. Simpson, Professor Tichborne and Mr. Wells of Dublin; Mr. Doran, Bray; Dr. Whitaker, and Messrs. Payne and Pring, of Belfast; Mr. McIlwaine, Newry; and Mr. Minchin, Athy.

The President said that since they last met the country had sustained a great loss by the death of the Duke of Albany. As loyal subjects he thought they should express their feeling on the subject, and he would, therefore, request them to allow the standing orders to be suspended in order that a resolution might be moved on the subject.

The standing orders having been suspended,

Sir George Owens moved the following resolution:—

"That this Council desires to place on record its sincere regret at the sudden death of His Royal Highness the Duke of Albany, and hereby expresses its deep sympathy with Her Majesty the Queen and the Duchess of Albany in the great affliction which has befallen them in the removal of one who was so bright an ornament of the State."

Mr. Pring seconded the motion, which was passed unanimously.

Mr. Allen moved, pursuant to notice, that—

"Candidates for the Society's licence shall give satisfactory proof of having attained the age of twenty-one years."

At present the Certificate Committee had not power to demand proof of that description, although they could require proofs from the candidate that he had attended chemical lectures, and spent two years at practical pharmacy. It had been found that one young gentleman had passed the examination for the licence who was not twenty-one years of age.

Mr. Payne said he had great pleasure in seconding the motion. He thought a certificate of birth from the registry office should be required.

Mr. Allen said it might be very difficult to give that particular proof sometimes. It would be quite safe to leave it to the Certificate Committee to decide what was satisfactory proof.

The motion was unanimously agreed to.

The President said the next business was the report of the Pharmacy Act Amendment Committee, which had been printed and was in the hands of every member. The Registrar would read it, and it could be discussed paragraph by paragraph. He (the President) supposed they had all seen the fate of the Bill promoted by the English Pharmaceutical Society—that the Government had declined to take up any portion of it except that relating to the sale of poisons.

Mr. Fennell then read the report. Clause 1 referred to the right preserved by section 31 of the Pharmacy (Ireland) Act to "chemists and druggists" who were practising as such in Ireland upon their own account, to continue their business, which carried with it the right to sell scheduled poisons; and recommended that power should be given to the Society to require all *boná fide* chemists and druggists who had been in business on their own account on or before January 1, 1884, to apply to the Council to have their names registered; such persons to pay on registration a fee of three guineas, and to be styled "Registered Druggists."

Agreed to.

Clause 2 recited that there were small towns and villages in Ireland where a highly educated pharmacist could not earn a livelihood, but where persons of proved intelligence and education as retailers of drugs and poisons for veterinary and household purposes were required, and recommended:—(A.) That the Council of the Society should be given power to hold examinations at stated periods for such persons, who, on passing the prescribed examinations and paying a fee of three guineas, should be entered on the registry of "Registered Druggists." (B.) That such persons should be examined with respect to their knowledge of the English language, arithmetic and elementary chemistry, and should have a practical knowledge of, and be able to distinguish by their appearance and by suitable tests the various drugs and poisons or poisonous substances in general sale. The rules affecting the examinations to be approved of by the Lord Lieutenant in Council.

Mr. Payne moved that clause 2 be omitted altogether from the report. The apothecaries of the past had carried on the compounding of medicines to the satisfaction of the public. The only drawback was that there was not enough of them. They merged into medical practitioners, and the profession of pharmacists was created to meet the want that was found to exist. He objected altogether to the creation of a third grade. The object of the Pharmaceutical Society was to provide a well-educated body of men to take the place of the apothecaries. In the country districts and small towns of Ireland there was not a great deal of compounding to be done, and unless the sale of poisons and poisonous drugs and the compounding of medicines were confined to pharmacists and apothecaries, it would be impossible for either of these to exist in such places. On the other hand, by maintaining that restriction they would give scope for the existence of a class of men who could not otherwise exist in those places. The creation of such a new grade as the recommendation proposed would not only be an injury to pharmaceutical chemists but to the public. It would be far better for the public to have thoroughly educated men everywhere. But if a second grade of registered druggists should be created and perpetuated they would have fifty times more illicit compounding then went on at present. The public would not distinguish between the registered pharmaceutical chemist and the other grades at all.

Mr. Doran seconded the motion. He had a feeling of considerable apprehension as to what the fate of the Society would be if the proposed new grade should be established. It would lead to no end of litigation and to prosecutions, for which the Society would have no funds. It would also prevent young men from coming up for the Society's final examination. Young men had told him that they would not go on for the final examination if the recommendation should become law.

Mr. Grindley said his hostility to the proposal under consideration continued as pronounced as ever it had been. He did not know on what grounds it was asserted that there was a deficiency of pharmaceutical chemists and apothecaries in Ireland. Every quarter that Society passed a certain number of men as pharmaceutical chemists. Country villages were generally supplied with medicines from the dispensaries, the dispensary doctor keeping open shop. It now took four years to make a pharmaceutical chemist, and they should not be like children, first sowing their seed in the ground and then rooting it up to see if it was growing. Let them strive to turn out a class of men who would serve the public satisfactorily and without falling into errors, and who would thus gain their confidence. If they created this grade they would render the practice of the pharmaceutical chemist worth nothing in the country. Instead of doing so they should strive to secure some encouragement for the young men who had passed their final examination. The present recommendation had been persistently put forward by a section of the Council who were beaten on it in 1878 at the Annual Meeting.

Mr. Minchin said he quite agreed with what had been said against the clause. He came from a small town in which it was perfectly true that a qualified man could not live by dispensing alone. An apothecary had this advantage, that he could prescribe for patients. A pharmaceutical chemist could not; he could only make up prescriptions. If the exclusive sale of poisons were taken out of the hands of pharmaceutical chemists they would have every grocer and hardware merchant in the country selling poisons.

Dr. Whitaker said that when the apothecaries of Ireland had the sale of these matters entirely in their hands they were urged to cease being medical men and to devote themselves entirely to the sale of drugs and medicines. They refused to do so, and the result was that the Government took the matter into their own hands and passed the Act under which pharmaceutical chemists existed. The Council ought, therefore, to take care that the public were not left without any accommodation that they required. The late Sir Dominic Corrigan called attention to the fact that in his time Celbridge, Lucan, Leixlip, Kilcock, and another town in the vicinity had not a druggist in one of them. And in places where a pharmaceutical chemist could not exist it was absolutely necessary to provide some means by which the farmers of the surrounding districts could get corrosive sublimate, arsenic, or any other thing of the sort that they wanted. Better that these matters should be supplied by somebody over whom the Society would have control than that it should be left in the power of members of Parliament to say that their constituents had to go thirty miles to buy sheep-wash. Supposing that the power which it was recommended that the Society should possess were granted, it did not follow that they would be obliged to use it indiscriminately. He was, on the whole, in favour of the clause.

Mr. Wells said that since the last meeting of the Council he had communicated with nearly all the pharmaceutical chemists in Ireland, except those of Belfast and Dublin. In the two cities just named there were not more than seventy pharmaceutical chemists, or at all events there were not more than a hundred. That left over a hundred scattered through the rest of Ireland, of whom at least forty were in business on their own account. These were in towns having a population up to four thousand, and there were sometimes two in each town. He believed that if they only continued to prevent hucksters and others from selling poisons and continued to endeavour to carry out their Act, in a few years all the small towns would have pharmaceutical chemists in them. He believed that it would be a great pity to make the proposed grade. Out of two hundred licentiates of the Society, he had ascertained that the opinions of a hundred and sixty were totally opposed to it. If the clause were carried two members of the Council would resign and several members of the Society would cease to subscribe to it, and if that went on they would soon have no Pharmaceutical Society at all.

Dr. Montgomery said he was under the impression that the Council had already agreed to the principle embodied in this clause.

Mr. Doran: Only by a majority of one.

Mr. Hayes supported the clause. He believed the proposed grade was required even more now than it was in Sir Michael Hicks-Beach's time. The existing arrangements were insufficient for the requirements of the country.

Mr. McIlwaine said he came from Newry, where there were three pharmaceutical chemists.

Professor Tichborne said there was something to be said in favour of the establishment of the proposed grade. No doubt there were small towns in Ireland where there were neither pharmaceutical chemists nor apothecaries, and that was the strong point for the clause. But there were a great many points against it. In his opinion, it was the original intention of the framers of the Act relating to the sale of poisons that the sale of such articles should be kept entirely in the hands of qualified men. At the same time they must bear in mind that it would be absurd to pass a law that it would be impracticable to carry out. It was undesirable to lay down the principle that the sale of poisons should be left in the hands of unpractised men. But if they passed the clause as it stood they would lay down that principle. Clause A. would tend to create a large body of men in towns where there was great competition, and it would not be long before they would try their hands at compounding.

Mr. Pring: They do it at present.

Professor Tichborne said he would propose the following amendment:—

"That it is desirable that the Council should seek powers to register persons for the sale of poisons in any post town in Ireland, where it is proved that there is no qualified man keeping open shop; and that candidates for the licence as registered druggists shall pass a prescribed examination."

This proposal he thought would meet the difficulty, for it avoided laying down the principle that it was desirable to create a new grade and only made an arrangement to meet an emergency. At the same time they would reserve protection for their own licentiates.

The amendment was not seconded.

The President said this question had been for some years before the Council, and they had almost all made up their minds upon it. Ever since he became a member of the Council he had felt strongly that a necessity existed for some such grade. Very small numbers of young men were coming up for their final examination. In Ireland, omitting the towns of large population, there were about two hundred and fifty towns having a population of from one thousand to two thousand five hundred, and it was in these and the districts surrounding them that the necessity for the proposed grade was felt. It would be cruelty to an educated man to fix him in some of those villages. It was quite within the power of the majority of the Council now to alter the decision that they came too not later than two months ago, but it would place them in a false position before the Government. There had been no public expression of feeling against this proposal from members of the Society outside the Council, and he had not had the slightest reason to believe that any number of members were opposed to it, except so far as was afforded by two or three anonymous letters in the press, which had no weight.

Mr. Payne observed that at the time when the late Sir Dominic Corrigan spoke of an existing want of extra accommodation, the Pharmaceutical Society was very young—it had not been more than twelve months in existence. Since then the Society had grown and many men had qualified themselves and were in business. Ballyshannon, which was a very small town, supported a pharmaceutical chemist, and also an apothecary. Clones had one pharmaceutical chemist; Athy had 2; Coleraine 2; Ballymoney 2; Newry 3; Monaghan 2; and Cookstown 1. These gentlemen would be still better able to maintain themselves if the sale of poisons were confined to them. In Belfast there were a number of pharmaceutical chemists and they objected very strongly to the creation of another grade; and he (Mr. Payne) was quite sure that if the pharmaceutical chemists in business throughout the country were asked their opinions as to this proposal, the majority of them would declare against it.

Mr. Grindley: They have been asked and we have their replies.

Mr. Wells: The Lord Lieutenant has already received a memorial against the proposal signed by over one hundred and fifty members of the Society, including ten members of the Council.

Mr. Payne said the plan of having an optional power would work most unsatisfactorily, because the constitution of the Council changed every two or three years, and the course which the majority of one year might decide on might be reversed by that of another.

The motion of Mr. Payne for the rejection of the clause was then put and carried by a majority.

The remaining clauses of the report were then dealt with.

Clause 3 recommended that it should be made unlawful for any save registered druggists, medical practitioners, pharmaceutical chemists, and apothecaries to sell patent drugs or poisons.

Agreed to.

Clause 4 recommended that it should be made unlawful for any registered druggist to keep open shop for the retailing, dispensing, or compounding of medical prescriptions.

Agreed to.

Clause 5 recommended that all registered druggists should pay an annual fee of 5*s.* to the Treasurer of the Pharmaceutical Society; that on or before the 15th March in each year a list of those who had paid should be forwarded to the inspector of weights and measures in each constabulary district, and that he should prosecute infringements of the law, and be entitled to one third of the penalty in each conviction.

Agreed to.

Clause 6 recommended that penalties for the infringement of the proposed enactments should be the same as and recoverable in the same way as under the Pharmacy Act.

Agreed to.

Clause 7 recommended that the word "person" in section 30 of the Pharmacy (Ireland) Act should be made to apply to all persons or associations of persons keeping open shop, and that each individual should be required to be duly qualified.

The President remarked that from what had happened with the English Bill he did not think there was much chance of that recommendation being included in a new Bill.

Mr. Wells: Perhaps the Government may do for us what they would not do for the Society at the other side.

The clause was agreed to.

Clause 8 recommended, in reference to the sale of patent and proprietary medicines containing poisonous ingredients, that a specification of the poisonous contents and the quantity of same should be printed on the label or wrapper; that the word "poison" should be printed on the various labels and wrappers, together with the name and address of the first seller; that the sale of such articles should be confined to legally qualified persons; and that persons convicted of contravening these regulations should be subjected to a penalty of £5 for the first offence, and of £10 for each subsequent offence: the seller so convicted to have power to recover from the owner of the medicine the amount of the penalty and costs on proof that the article had been sold in the same condition in which it had been received.

Agreed to.

Clause 9 recommended that a pharmaceutical chemist or apothecary keeping more than one open shop for the sale of poisons or medical prescriptions should employ in the shop in which he was not engaged a person who would himself be a duly qualified keeper of such shop.

Agreed to.

Clause 10 recommended that proprietors of shops for the sale of poisons and the compounding of prescriptions should be obliged to furnish, on application in writing, their names, addresses, and qualifications to the Registrar of the Pharmaceutical Society, under a penalty of £5 for each day of default, and that any person selling in the shop during such default should be liable to a penalty of £5 for each offence.

Agreed to.

Clause 11 recommended that any person fraudulently procuring himself to be registered, and anyone aiding or abetting him, should be deemed guilty of a misdemeanour, and liable to imprisonment for a period not exceeding twelve months.

Agreed to.

On the motion of Mr. Payne, seconded by Mr. Grindley, the recommendations as amended were adopted, and ordered to be printed, and copies sent to the Chief Secretary and to the Irish Members of Parliament.

Some other business having been disposed of, the Council adjourned.

Provincial Transactions.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

The fourth ordinary meeting of the above Association was held at the Owens College, on Tuesday evening, March 25. Mr. W. Wilkinson, Vice-President, in the Chair.

The minutes of the last meeting having been read and confirmed, the Chairman called on Mr. F. C. J. Bird to read a paper on "New Remedies," which was illustrated with specimens from the Owens College Materia Medica Museum.

Some Short Notes on New Remedies.

BY F. C. J. BIRD.

The author stated that the past few years had been remarkable for the large number of drugs (chiefly of vegetable origin) which had been brought under the notice of the medical profession, and highly recommended as specifics in various diseases. Many of these had attained popularity for a few months, and then not realizing the expectations of those making use of them, had quickly disappeared from prescriptions only again to be met with occasionally. Although this rage for new preparations was at times very perplexing to the physician, still it was not without its advantages, for should a hitherto unknown drug possess any real merit, it would stand a chance of getting a trial, and instead of remaining uselesss and unappreciated in its original habitat its remedial qualities would be utilized for the benefit of mankind. The greater part of these new remedies were of both American origin and introduction, and appeared to have been discovered or at least first used pharmaceutically by the eclectic practitioners of America, whence many of them are commonly termed "eclectic remedies." The word "eclectic" really meant selected, but now conventionally it is understood to refer to a class of medical men in America, who confined the drugs used in their practice to substances obtained from the vegetable kingdom only, and who, when they have exhausted the drug by treating it with alcohol, precipitating the tincture with water, and drying the resulting resinoid powder, believed the preparation thus produced to represent the entire active constituents of the drug divested of all inert woody matter, etc. For a long time this class of practitioners was regarded to a certain extent, by medical men of the other school, in the light of quacks, but the valuable qualities of some of their now well-established remedies, as podophyllin, iridin, etc., have done much to remove that feeling.

The author then proceeded to describe in detail the following drugs, their uses and applications:—*Berberis aquifolium*, *Rhamnus purshiana*, *Grindelia robusta*, *Aspidosperma Quebracho*, *Loxopterigium Lorenzii*, *Convallaria majalis*, *Lippia Mexicana*, *Viburnum prunifolium*, *Francisca uniflora*.

After the reading of the paper a discussion ensued, in which the Chairman, Messrs. Elborne, Benger and Kirkby took part.

Mr. Bird having replied, the Chairman then called on Mr. Kirkby to read his paper on "Kamala."

This paper will be printed in an early number.

After the reading of the paper a discussion followed, in which the Chairman, Messrs. Elborne, Benger and Hermann Woolley took part. Mr. Kirkby having replied, hearty votes of thanks were accorded to Messrs. Bird and Kirkby for their admirable papers, which were carried with acclamation.

Mr. Elborne then drew the attention of the meeting to some recent donations to the Owens College Materia Medica Museum, which gave rise to a discussion, in which the Chairman and Mr. Hermann Woolley took part. The meeting then terminated.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Thursday evening, March 27, Mr. W. Buckley read a paper before the members of the above Association on the subject of "The Doctrine of Evolution." The chair was taken by Mr. A. E. Martin, President.

The essayist commenced by defining the term, and remarked that it was generally confounded with the Darwinian theory, and gave an extract on the meaning of "Evolution" from Dr. Hooker. He then proceeded to describe the various forms of animal life, beginning with the gregorina, and treating the other forms to the vertebrata. Gregorina was described as an animal which is found as a parasite of the cockroach, which takes in its food in any part of its surface. This is the lowest form of animal life. Amœba was then described as *seizing* its food, which is forced through the mass of protoplasm and excreted anywhere. Infusoria formed a step higher, in the possession of a definite mouth and œsophagus and egestive region. Waterweed hydra, sea anemone, entozoa, earthworm, leech, insect, vertebrata were all described in order of superiority, the various changes in the structure of the same being pointed out until the highest form of animal life was reached in the case of vertebrata. He then explained evolution of reproduction, descrlbing the mode of reproduction (in the first place) of the gregorina by incystation, that is, the animal surrounds itself by a mass of gelatinous matter and then splits up, each part becoming a fresh animal. Infusoria were described as being reproduced by splitting into two equal parts and also by budding, a portion becoming attached to the animal, and after some time becoming free, and having the powers of its predecessor. The different modes of reproduction were fully described in each case, to the vertebrata as in the human being. The whole of the descriptions were most interesting and easy to follow, as the essayist handled the subject in a masterly manner. The descent of man was next noticed, Mr. Buckley showing the similarity of the structure of some monkeys to human beings—more especially the chimpanzee and gorilla. The useless muscles of the human body were spoken of and the reason why they were useless explained. The facts of evidence of relationship of some apes to man was fully treated upon.

The whole of the paper was most interesting and was enjoyed by all present, as their great attention to the delivery of the same showed.

After a discussion, in which the arguments antagonistic to the Darwinian theory were given and discussed by most of the members present—

Mr. J. Lees proposed a vote of thanks to Mr. Buckley, which was seconded by Mr. C. G. Wood (Sec.) and carried.

HAWICK PHARMACEUTICAL ASSOCIATION.

The monthly meeting of the above Association was held on the evening of Tuesday, the 1st inst. The Hon. President (Mr. Maben) occupied the chair. There was a large attendance.

The minutes of the former meeting having been approved,

Mr. M. Dechan, Analytical Chemist, read a paper on "Milk and Milk Analysis." Referring first of all to milk as an article of diet, Mr. Dechan showed by reference to its composition that it was a perfect food. It contained all the substances that were required for the nourishment of the various parts of the body, and these in the proportions in which they were most required. Milk consisted largely of water, which was necessary as the basis of the blood and of the various juices of the system; it contained the nitrogenous constituents essential for producing muscle, and repairing the continual waste of tissue, as well as the sugar and fats required for maintaining the animal heat, and the mineral matters or ash, which went to form bone. Going on to consider the milk of different animals, he pointed out that mare's milk contained the largest proportion of sugar and the smallest of the albuminoids and fats, the milk of the ass coming next in these respects. On this account these milks were peculiarly valued as a diet for consumptive patients. With regard to the sugar and the proteids they came nearer the composition of woman's milk than that of any other domesticated animals, but the same remark did not hold good of the fat, which was present in human milk in somewhat similar proportion to that in which it occurs in the milk of cows.

Proceeding to the second part of his subject, the analysis of milk, Mr. Dechan pointed out that here, of course, we have usually only to do with cow's milk. In the first place, there was great difference of opinion regarding its percentage composition, or, rather regarding what ought to be looked on as genuine milk. Different cows, and even the same cow on different food, varied as to the quality of their milk. This had led to disputes in which a certain amount of bad feeling had been shown among analysts, some, and these the large majority, maintaining most strenuously that genuine cow's milk ought to contain not less than about 12 per cent. of total solids, and that even this was a very low estimate, while others hold that milk had been got with a much lower percentage than this. The natural result of this conflict of opinion was that the public interest suffered. Endeavouring to account for the way in which these discrepancies might have arisen, Mr. Dechan explained that in milking cows, the milk that flowed first was poorest in fat, while that last drawn was poorest in solids not fat. It might, therefore, have happened that samples of milk from one portion only of the milking had been analysed, and while in one sense this was perfectly genuine milk it was obviously quite unfair to take it into account in fixing a standard.

Then, again, there was a difference of opinion as to the method by which milk should be analysed. Having described Wanklyn's method, that of Somerset House, and that approved by the Society of Public Analysts, Mr. Dechan critically examined each, pointing out that no one was in all respects perfect. He then explained the method which he had been using, along with Mr. Maben, for some time. This consisted essentially in employing a continous extraction apparatus, modelled on the principle of Soxhlet's tube, and using ether as a solvent. By this means the fat was readily and completely separated from the solids not fat. These were then dried, and their combined weights corresponded, when the analysis was correctly carried out, with the total solids which were determined separately. The amount of ash was obtained by igniting the solids not fat, and weighing the residue. Milk analysis did not go further usually than this, but if the proximate constituents of milk were all required the solids not fat would be again analysed to ascertain the proportions of proteids and milk sugar, and the ash for the amount of phosphate of lime, chloride of sodium, and other salts.

Mr. Dechan was listened to throughout with great attention, and, at the close of his paper, which had been illustrated with diagrams, he received a hearty vote of thanks.

Several questions having been put and answered, it was intimated that the annual business meeting of the Association would be held next month.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eleventh general meeting of the thirty-fifth session was held, at the Royal Institution, March 13, 1884. Mr. Edward Davies, President, in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations to the Library were announced;—*The Pharmaceutical Journal*, from the Society, and the *Science Monthly*, from the Editor.

The President announced that in accordance with the intimation he gave at the last meeting respecting the letter of resignation from their Vice-President, Mr. Alfred H. Mason, that same had been brought before a Special Council Meeting, and that it had been resolved to accept same with deep regret, and also to make Mr. Mason an honorary member of this Association.

Mr. Arthur Crosfield, was then elected a member.

Mr. J. C. Bredin described experimentally a test for the detection of nickel and cobalt, by means of the ferro- and ferri- cyanides of potassium, which he stated was employed by Mr. R. H. Davies, and described in the *Chemical News* (vol. xxxii., p. 44).

Mr. J. T. Hornblower exhibited purified crystals of barosma camphor, the stearopten of buchu oil, which was obtained from *Barosma betulina* and *Barosma serratifolia*.

Dr. Symes exhibited some leaves, which were packed with a parcel of kola nuts, and which he found on examination to be the leaves of the kola plant.

The President then read a paper entitled—

Notes on Testing for Arsenic.

BY E. DAVIES, F.I.C., F.C.S.

In all ages poisoning has been a crime which has excited the greatest amount of reprobation, both on account of the cowardly nature of the attack on the life of the victim, which leaves him without the means of defence, and also from the difficulty of its detection. In olden times before chemical analysis was discovered, chemistry, as then known, was long employed for the preparation of deadly agents. Indeed, if we could credit the tales of Italian and French poisoners, we should have to admit that they were far in advance of chemists of our own time, as they were believed to be able to administer poison in gloves, perfumes, and even so to prepare the leaves of a book that by touching with the fingers and then moistening them with the saliva in order to turn over the pages, enough poison could be taken into the system to produce death. We read of mysterious concoctions of herbs, distillation of compound mixtures, necessitating the use of glass masks,—by the way, a most futile precaution against the inhalation of poisonous fumes,—and all the paraphernalia so useful to the romance writer who wishes to give a great scientific-dramatic colouring to his works. No doubt the poisoners of that day did, in their ignorance of the chemical nature of the materials on which they worked, combine—

"Eye of newt, and toe of frog,
Wool of bat, and tongue of dog,
Adder's fork, and blind-worm's sting,
Lizard's leg, and owlet's wing,
For a charm of powerful trouble,"—

but the really active ingredient was some simple substance, such as aconite, sugar of lead, and above all, arsenic.

About 1700, a woman named Toffana or Tophania, living at Palermo, and afterwards at Naples, attained a baleful reputation by her preparation of a poison known as "aqua della Toffana." In Beckman's 'History of Inventions,' it is stated that this preparation, as well as that employed by the Marchioness de Brinvilliers, were almost certainly "arsenical mixtures, or as Dr. Hahneman rightly conjectures, neutral salts of arsenic. Loss of appetite, faintness, gnawing pains in the stomach, loss of strength without any visible cause, a continual indisposition, followed by a wasting of the viscera, a slow fever, etc., are all symptoms which seem to announce that dangerous metallic oxide." And in a note he adds an extract from 'Hoffmanni Med. rationalis System.' p. ii., c. 2, section 19, 1718 or 1719. "Garelli, the Emperor's principal physician, lately wrote to me something remarkable in the following words:—'Your elegant dissertation on the errors respecting poisons, brought to my recollection a certain slow poison, which that infamous poisoner, still alive in prison at Naples, employed to the destruction of upwards of six hundred persons. It was nothing else than crystallized arsenic, dissolved in a large quantity of water by decoction, with the addition, but for what purpose I know not, of the herb cymbalaria. This was communicated to me by his imperial majesty himself, to whom the judicial procedure, confirmed by the confession of the criminal, was transmitted. This water, in the Neapolitan dialect, is called aqua del Toffnina. It is certain death, and many have fallen a sacrifice to it.'" The allusion to neutral salts of arsenic is especially interesting, as the arsenate and arsenite of soda have just attained such prominence as poisonous agents.

The truth is that it was not so much the mysterious nature of the poison employed as the inability of the chemists of the day to detect small quantities of mineral poisons which gave to mediæval poisoners the impunity which they often enjoyed.

Previous to the introduction of Marsh's test there was no method by which small quantities of arsenic could be detected. Mr. Marsh, of Woolwich, discovered this process in 1836. It can, no doubt, detect smaller traces of arsenic than any other, but it has two great disadvantages. It cannot be used when a small quantity of arsenic is contained in a large quantity of organic matter, until the organic matter has been destroyed, as the frothing occasioned by it is an insuperable obstacle. Its extreme delicacy is almost an objection, as, though the zinc and sulphuric acid can be tested absolutely in the apparatus, the same is not the case with all the chemicals which have been used in the preparation of the solution. This is not the case with Reinsch's and Fresenius' tests, in each of which everything can be tested in blank experiments.

Reinsch's test, first proposed in 1843, is still, in many respects, the most useful test for the detection of arsenic. A slip of copper, boiled with the suspected material, acidulated with hydrochloric acid, soon becomes coated with an alloy of arsenic and copper. The mere staining of the copper alone is not a sufficient indication of the presence of arsenic. Antimony, mercury, and, in some instances, it would appear, organic matter, may produce a stain resembling that caused by arsenic. By heating the slip in a tube closed at one end we get the arsenic volatilized, and then oxidized into arsenic trioxide. I have found that if the part of the tube upon which the crystals of As_2O_3 are to be deposited is first warmed, the crystals are much more distinct and perfect in crystalline form. Another point which I have found exceedingly important, is to remove any fatty matter which may have deposited on the copper slip, by boiling it in ether. In all cases in which animal matters are boiled with the slip and acid, fatty matters are present and often adhere strongly to the copper. If they are not removed fatty globules of fat and tarry matters mix with the crystals and render them indistinct.

I have also made some experiments to ascertain whether sulphide of arsenic would give the reaction with Reinsch's test. One-tenth of a grain of arsenic trioxide dissolved in water was precipitated as sulphide, filtered and washed thoroughly with water. The precipitate was divided into two parts, and one part, equal to one-twentieth of a grain, was boiled with about one ounce of water acidulated with HCl, and a slip of copper introduced. It was some time before the copper was stained, but in two hours it was completely coated, and a fine deposit of As_2O_3 obtained by sublimation. It thus appears that the test may be applied successfully in any case, however long a body may have been interred.

A great merit of the process is the fact that no previous preparation of the organic matter is necessary, and as both acid and copper can be sufficiently tested by gently simmering the acid diluted with three or four times its bulk of water with a slip of the copper for five or six hours, there is no risk of introducing any arsenic into the material.

To some extent this process may be used for quantitative determination. By boiling the material with successive slips of copper until no more are stained, on heating in a capacious tube the arsenic is obtained free from organic matter. It may then be dissolved and precipitated at As_2S_3. It, however, takes a long time to remove all the arsenic, and some other method is desirable which will enable larger quantities of material to be acted on. Many have been devised for destroying the organic matter, which may be summarized as follows:— 1. Destruction by sulphuric acid alone or in conjunction with nitric acid. These methods involve the use of large quantities of sulphuric acid with risk of thus introducing traces of arsenic, and on the other hand all animal matters contain small quantities of chlorides, and on heating with strong sulphuric acid chloride of arsenic is sure to be formed and volatilized. 2. Oxidation by means of nitrate of potash. Large quantities of nitre must be used, or if the carbon is not entirely burnt, arsenic in the elementary state will be evolved. Then the nitrates and nitrites in the residue must be entirely decomposed by sulphuric acid. This introduces the former objections.

Dr. Taylor advocates the thorough drying of the organic matter and then adding strong hydrochloric acid and distilling. The distillation should be carried to dryness and repeated when the arsenic will be volatilized and condensed in the receiver. This method does give good results sometimes, but it is very difficult to get the organic matter quite dry, and the contents of the retort are very apt to bump. The distillate is not free from organic matter.

The process known by the name of Fresenius and Babo's consists in heating the organic matter with hydrochloric acid, so that the strong acid shall not be more than one-fourth of the bulk of the water present or if necessary added. Chlorate of potash is added in successive small quantities until the solution is a light yellow colour. This is filtered and the residue thoroughly washed. The filtration takes place rapidly and a clear liquid is obtained. The filtrate is heated for some time to remove any chlorine, then boiled with pure solution of sulphurous acid, the excess of sulphurous acid boiled off and well washed. Sulphuretted hydrogen is then passed in slowly for two or three hours. The liquid is gently warmed for some time to remove excess of H_2S, and the precipitate filtered off and washed until quite free from chlorine. The precipitate and filter are dried and treated with pure fuming nitric acid. The residue is dried and moistened with strong sulphuric acid. After heating for some time on a water-bath, it is heated for two hours in an air-bath at 150° C. The charred mass is then boiled with dilute HCl and H_2S passed in. The sulphide of arsenic is then precipitated pure and is most conveniently weighed by dissolving off the filter with dilute ammonia and evaporating to dryness in a weighed porcelain dish. It is well to moisten with strong H_2S solution and evaporate again. The sulphide may then be oxidized with fuming nitric acid, and the solution of arsenic acid tested in various ways.

Objections have been raised with regard to this process. First, it has been supposed that arsenic may be lost in the first treatment. The HCl is too weak to admit of the formation of chloride of arsenic, but as the operation may very well be conducted in a retort any loss can be prevented. The complexity of the process has also been urged as an objection, but in practice this is not found to be the case. There is rather a large number of reagents used, but the quantity of each is small, and besides testing each separately a blank experiment can be easily made, where by using meat for organic matter and double quantities of each reagent the purity of the whole can be proved. Practically, I have never failed to find arsenic by this process when Reinsch's process has shown it to be present, and I have never found it when Reinsch's test has shown it to be absent.

Fresenius and Babo's method has the advantage that it enables us to ascertain the presence of other poisonous metals without the introduction of copper.

Dr. Nevins said he had listened to the paper with very great interest, as the subject of it was one in which he had taken a practical interest during many years of chemical experience. He concluded by moving a hearty vote of thanks to Mr. Davies.

Mr. Conroy, in seconding the vote of thanks, considered the paper showed a most valuable digest of the facts of a long practical experience, and he hoped it would be published, as it would prove a most valuable record for future reference.

The discussion was continued by Dr. Symes, Mr. Ward and Mr. A. C. Abraham, and the vote of thanks was carried by acclamation. Mr. Davies having replied, the proceedings terminated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, April 3. Dr. W. H. Perkin, F.R.S., President, in the chair.

The following certificates were read for the first time:—R. St. Stephens and R. C. Tresidder.

Professor P. T. Cleve, of Upsala, was present at the meeting, and was formally admitted as a Foreign member.

Mr. Salamon read a paper—

On the Influence of Certain Phosphates upon Vinous Fermentation. By A. G. Salamon and W. de Vere Mathew.—Considerable difficulty is often experienced in the course of the manufacture of beer by the method of high fermentation, in producing a sufficient attenuation of the wort in a given time. Under such circumstances it is constantly urged that the addition of certain salts of phosphoric acid will exercise such a stimulating influence upon the growth of the yeast organism as to materially increase the rapidity of the attenuation of the wort. The authors undertook the present series of experiments to determine whether such a stimulation is really obtained. They have estimated the vigour of the fermentation by the amount of sugar consumed in a given time; the sugar left after the fermentation being determined gravimetrically as recommended by O'Sullivan. The following Pasteur's solution was used as a fermenting medium:—Water, 100 c.c.; potassium phosphate, 0·233 gram; calcium phosphate, 0·02 gram; magnesium sulphate, 0·023 gram; ammonium tartrate, 1·166 gram; cane sugar, 17·490 grams. The temperature of the solutions was maintained at 60° F., and the duration of the experiments was usually sixty hours. The following may be given as an example of the experiments. One hundred c.c. of Pasteur solution were used with 5 grams of pressed yeast.

Sugar consumed in grams. Per 100 c.c.	Potassium phosphate in grams. Per 100 c.c.
8·5770	0·0000
8·5896	0·0575
8·5001	0·1150
8·7666	0·1720
9·6884	0·2300 (= ·0770 P_2O_5)
9·9124	0·2875
7·7586	0·3450
7·5948	0·0425
7·8878	0·4600
7·2850	0·5175

Time, forty-eight hours.

It is seen that the maximum fermentation occurs when 0·23 gram of potassium phosphate is present per 100 c.c. which is the normal amount in Pasteur's solution, a larger quantity is obviously fatal to the proper activity of the yeast ferment. Similar experiments proved that although small quantities of calcium and magnesium phosphates were benficial an excess was most injurious. Now the normal amount of P_2O_5 in an English beer wort is about 0·1160 gram, and in the normal Pasteur solution 0·0875. The ordinary wort contains therefore an excess of P_2O_5 over that which has been found to be most favourable to fermentation, hence it follows that it is not advisable to add phosphates for the purpose of accelerating the attenuation of ordinary beer worts.

The President asked if the authors had made any experiments to decide whether the alteration in activity was due to the potassium salts or the phosphoric acid.

Mr. Warington said that in the tables where the authors had stated the phosphoric acid as 0·00 gram the P_2O_5 in the yeast still had to be taken into account, because probably if no P_2O_5 were present no yeast growth or transformation of sugar would take place. It seemed that it was not at all proved that the action was due to the phosphoric acid. It would be interesting to know what would happen if another salt, as potassium sulphate, was substituted for potassium phosphate.

Mr. Salamon said that their object was to ascertain whether it was advisable to add phosphates to the wort or not, and from the experiments it seemed that this question must be answered in the negative.

The Secretary then read a paper—

On the Occurrence of Rhabdophane in the United States. By W. N. Harley.—In the *American Journal of Science*, xxv., 459, Brush and Penfield describe a new mineral from Salisbury, Conn., under the name of scovellite. This mineral agrees in physical properties, etc., with rhabdophane (*Chem. Soc. Journ. Trans.*, xli., 210), and seems to be a variety of that mineral containing erbium and yttrium, associated with lanthanium carbonate. In a subsequent number of the *American Journal of Science*, March, 1884, Brush and Penfield have recognized this identity of scovellite with rhabdophane.

The Society then adjourned to April 17, when a paper on "The Synthesis of Galena," by Emerson Reynolds will be read.

SOCIETY OF ARTS.

Alloys used in Coinage.

The final lecture of the Cantor course on "The Alloys used for Coinage" was delivered by Professor Roberts on the 7th inst., and treated more especially questions connected with the liability to reduction in weight of various coins by wear during circulation, and the different modes in which coins are liable to be criminally tampered with. Abstracts from the laws relating to the tests to which coins should be submitted were read by the lecturer, who showed clearly how the present laws were based upon and nearly equivalent to those of very early date. He then described various methods that have been employed to correct gold coins which are either slightly above or below the standard weight, 123·274 grains if the coin be a sovereign, or 61·637 grains if it be a half-sovereign. The adjustment has been made by means of a hand-file up till quite a recent date, and some ingenious mechanism has been invented for the same purpose, but the disadvantage of any mechanical method is that the marks of the file or other instrument are never entirely obliterated. Chemical aid has been called into request, and amongst other methods the coin has been subjected to the solvent action of *aqua regia*, but this could only be used when the coin was too heavy. Another method of greater efficiency is the immersion of both the light and heavy coins in a solution of potassium cyanide, and the passage of an electric current through the coins; the result, as Professor Roberts showed by experiment, being that a small portion of the alloy is passed from the heavier coin to the lighter, thus bringing them to the same weight. In the course of the evening the lecturer drew attention to an ingenious apparatus used at present in the Royal Mint, by which the coins above or below the remedy of the standard weight are rejected. Professor Roberts did not attempt, however, to give more than an idea of the working of the machine, a working model of which he had present, but referred persons interested to the 'Encyclopædia Britannica' for details. He then remarked upon the illegal tampering with coin and the steps taken to prevent it. The old method of clipping coin had been prevented by laws enacting that no coin should be tendered in which the sculpture or outside ring did not remain whole; but the lecturer considered the best method of preventing clipping was, the lettering or milling of the edge of the coin. An ingenious method, which Professor Roberts jokingly classed as an American industry, consists in splitting the gold coin and removing the middle portion, after which base metal is introduced in place of the gold alloy extracted and the coin again made whole by soldering. Formerly, coins were weighed by the pound and not separately as at present, so that many of the coins though far heavier than they should be were circulated owing to the presence of light coins. A profitable, though illegal employ of culling coin, that is to say extracting the heavier coins, was extensively carried on, and numerous instances were cited of cases concerning this practice appearing before the Star Chamber. The liability to reduction in weight by wear in circulation would be greatly influenced by both the form of the coin and the nature of the alloy. Theoretically a perfect sphere would be the most durable shape for a coin, as combining maximum weight with smallest surface, but this, as well as a short cylinder, would be a very inconvenient shape; the present cylindrical form is therefore used. Further, a coin struck in low relief would present less chance of disfigurement than one of high relief. If coins of pure metal be brought continually into contact with each other they will soon be reduced to the state of mere counters; but the slightest addition of base metal to form an alloy is followed by a marked difference in the durability of the coin. Experimentally it has been proved that there is no appreciable difference in durability between the English and continental standard alloys; the annealing process also greatly contributes to enable the coins to resist wear in circulation. The rate of wear is fairly uniform, the new coins losing nearly the same amount of metal as old coins, the annual loss averaging about 0·043 grain; thus a coin of standard weight will keep in circulation about eighteen years before falling below the remedy allowed by law. These remarks do not apply to bronze coins, which are withdrawn from circulation when defaced. It is remarkable that at the present time only about one-third of the gold and silver coins struck are retained in circulation in this country, the remainder, which formerly formed a much larger proportion, being exported or melted down as bullion. In reference to some experiments which Professor Roberts had himself made, he stated that coins of aluminium resist wear to a singularly high degree, which is further raised by a slight addition of nickel. In concluding he remarked that the Government would take no steps in the improvement of coinage until urged to do so by the people, who at present had no idea of the main features of the question.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, March 27, Mr. H. G. Greenish, Vice-President in the chair.

The first paper read was on "Unofficial Indigenous Materia Medica," by E. J. Eastes.

The paper will be printed in a future number of this Journal.

The paper was illustrated by dried specimens of the plants alluded to, and was followed by a discussion in which the Chairman, Messrs. Dymond, Ince, McDiarmid, and Short took part.

A vote of thanks was passed to Mr. Eastes.

The Secretary (Mr. Dunstan) then made a Report on Organic Chemistry on "Metethaldehyde."

The paper will be printed in a future number of this Journal.

The report was experimentally illustrated and was followed by a discussion in which the Chairman, Messrs. Dymond, Evans and Lowe joined.

A paper was next read by the Secretary—

Note on the Crystallization of Sodium Hydrate.

BY R. A. CRIPPS.

A short time ago I had occasion to prepare a very strong solution of sodium hydrate, and was somewhat surprised to find that after a short time long colourless crystals appeared in the liquid. On examination they proved to be hydrate of sodium. I found by reference to Watts's 'Dictionary' that this result had previously been obtained, but no formula is given for the crystals. To determine this the water of crystallization was estimated by heating the previously dried crystals to fusion, and was found to be 38·01 per cent. The sodium hydrate was also estimated and 62·91 per cent found. These figures agree sufficiently well with the formula $3NaHO, 4H_2O$, which requires 37·5 per cent. of water. The melting point was about 60° C., but the extremely deliquescent nature of the crystals rendered its accurate determination difficult.

The conditions most favourable for the production of the crystals are as follows:—One pound of sodium hydrate in sticks (preferably containing a little sodium chloride) is packed in a cylindrical glass vessel, a tall beaker for instance, of such a size that on adding 7½ ozs. of water the sticks are just covered; the whole is well stirred at intervals during a quarter of an hour, and then another ounce and a half of cold distilled water stirred in, after which the whole is set aside for about an hour and a half, about one third of the soda being still undissolved. At the end of that time the temperature will have fallen to about 40° C., and the crystals will have separated; the liquid is decanted from the crystals, which are allowed to drain and lastly dried *in vacuo* over sulphuric acid. The temperature of the solution should not be allowed to get quite cold, as the whole then becomes pasty and the crystals cannot be separated.

Potassic hydrate treated in the same manner gave no indication of crystallization.

A specimen of the crystals was exhibited.

After some remarks by the Chairman, Secretary and Mr. Ince, a vote of thanks to Mr. Cripps was passed.

Miscellaneous business being announced, Mr. P. L. Huskisson showed some very large crystals of phosphoric acid, about three inches in length, and some crystals of potassio-ferric oxalate which had been produced during the evaporation of an impure solution of neutral potassium oxalate.

Both these specimens have been presented to the Museum of the Pharmaceutical Society.

The meeting then adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above Association, held on March 26, 1884, Mr. Parkinson (President) in the chair, a paper on "Emulsions" was read by Mr. Joseph Ince.

The author commenced by defining an emulsion as in most cases a mechanical mixture of two substances which are insoluble the one in the other, and the surfaces of which when brought together do not adhere but rather repel each other, and pointed out that in such instances mechanical mixture cannot be readily maintained unless something be added which can establish a sufficient amount of adhesion to overcome the tendency to separation. The author then described the methods by which emulsions are best prepared, there being two distinct directions to be given to trituration in making an emulsion. In a mortar the action is towards the dispenser; on a pill tile or slab, the action is from the dispenser; the first from left to right, the second from right to left; right and left are determined by the position occupied by the mortar or slab as it faces the operator. There are also two distinct mechanical applications to be used; viz., almost total absence of pressure in the case of liquids, and vigorous pressure in the case of solid substances to be reduced into a fine state for forming an emulsion. Slight modifications occur in practice which may be trusted to the good sense of the dispenser, but the main principle holds good. When liquids, limpid or viscous, are to be combined, the very gentlest manipulation should be employed; increase of pressure generates heat, and heat is fatal to union, thus when olive oil, mucilage and water are to be emulsified, while care must be taken to have the three entirely under the control and action of the pestle, at the same time lightness of hand cannot be too carefully studied. The common advice to press vigorously on the bottom of the mortar will be found to be incorrect. On the other hand, when a solid has to be broken down and worked into a pasty saponaceous mass an exactly opposite mode of treatment must be adopted. The object is to produce a kind of soap which can be only extemporaneously manufactured by strong continued muscular action, with evolution of heat to effect the change. Myrrh, ammoniacum and similar substances may be taken as examples which require this treatment. The author then alluded to several emulsions individually, first giving the following as a type of an excellent emulsion:—

℞ Ol. amygdal dulc.		ℨiss.
Mucilag. acaciæ		℥iij.
Syr. simp.		ℨiss.
Aq. dist.	ad	℥iij.

Here the chief points to be observed are absence of acidity from the mucilage, lightness of hand and quickness in manipulation. Mist. ferri co., B.P., was then mentioned, various ways of manipulation being given, the following method being considered the best: beat the myrrh as usual, divide with the sugar, add the potash and make a thick creamy emulsion with just sufficient water, let them stand covered from the air over night and the following morning finish the operation. A few minutes' trituration will restore the whiteness, and such a mistura ferri co. will keep for some years without alteration. Methods for the best ways of emulsifying ammoniacum, assafœtida, guaiacum, etc., as well as ol. terebinth., were all fully described.

In the discussion which followed, the President, Messrs. Flintan, Millhouse, Taylor and others took part.

A vote of thanks to Mr. Ince for his valuable paper terminated a very successful meeting.

Obituary.

PETER SQUIRE, F.L.S.

With profound regret we put on record the death of Mr. Peter Squire, on Sunday last, at his residence, York Gate, Regent's Park.

Mr. Squire was born at Stratton, in Bedfordshire, in 1798, and therefore at the time of his death he was in in his eighty-sixth year. At the age of fourteen he was apprenticed to a chemist and druggist at Peterborough, and like many other apprentices of those days seems to have had an experience which, however conducive to a mastery of the minutest details of the business, was scarcely so favourable to the comfort of the apprentice. Notwithstanding the disadvantages of long hours,—seven a.m. to eleven p.m.,—the lad, having a love for botany, gave life to his studies of a folio edition of Sir John Hill's 'Herbal,' by the examination of flowers collected in early morning rambles in the fields. In this way he laid the foundation of the sound knowledge of botany which in after years was to be so useful in his business and in the examination room. Shortly after the termination of his apprenticeship he came to London and entered the house of Wilson, Minshull and Co., Snow Hill, where he became the head of the "wet" department and supervisor of the laboratory. Three years afterwards he took charge of the "dry" department in the house of Hodgkinson, Brandram and Stead, Thames Street. From thence he went to Oxford Street to live with Mr. Alexander Garden, the partner of Frederick Accum. There he spent eight years, during a portion of which he enjoyed a share in the business, and at this time his attention seems to have especially turned to the study of chemistry, the lectures which Brande and Faraday delivered at that time at the Royal Institution to the pupils of St. George's Hospital at eight and nine in the morning being attended. The partnership with Mr. Garden having expired, and the position being taken by that gentleman's own son, Mr. Squire paid a visit to Paris, where through an introduction by M. Bertin, the physician to Prince Polignac, then French Ambassador in London, he acquired the privilege of attending the pharmacy of M. Beral in the Rue de la Paix, and thus acquired an insight into the way the business was carried on in France.

Having thus acquired experience from various sources, Mr. Squire, about the year 1831, bought the business in Oxford Street, with which he remained associated for upwards of half a century, from a Mr. Scott, who had carried on a dispensing business there for forty years previously. Mr. Squire now turned his attention to the improvement of medicinal extracts. At that time scarcely one of them could be distinguished from another either by colour or odour. It was impossible for Mr. Squire to prosecute any researches during the day, as he was occupied from seven a.m. to eleven p.m. He accordingly resolved to enter upon a series of experiments after supper and when others had retired to their beds he descended into the laboratory where he remained until one, two, three, and sometimes even four o'clock, as the various experiments might render it necessary, for he never felt exhausted.

The result of these experiments was that these important preparations for the first time appeared with their proper physical characters apparent by the peculiar colour and odour of the plant from which they were derived. The dried leaves and the tinctures made from them next received his attention, and acting under the belief that as the leaves of plants during the process of drying must necessarily be chemically acted upon by the air, the juices expressed from them, preserved by only just enough spirit to keep them from change, might prove superior to tinctures, he, in 1835, made some such preparations of conium, belladonna, digitalis, hyoscyamus, and other plants, and had them tried by his medical friends. He was soon persuaded of their advantage. The digitalis preparation was much employed by one practitioner, who declared that he could bring down the pulse far lower by the preserved juice without producing nausea than he could by the tincture.

These researches of Mr. Squire brought him under the notice of many eminent medical men. Amongst these was Sir James Clark, then Dr. Clark, who was no mean judge of pharmaceutical preparations. He made many visits *incognito*, examined the several tinctures and other preparations with apparent interest, and frequently spent half an hour in conversing upon medicine. Dr. Clark kept his *incognito* until he was satisfied by every inquiry, and then, sending for Mr. Squire, said, "You will recollect our frequent conversations. I have made the inquiries about your general character, and I wish you now to sit down and give me an account of yourself, where you were educated, and what progress you made at school; where apprenticed, and by what means you have acquired the knowledge that you evidently possess of your business." This being answered, he handed Mr. Squire a prescription for H.R.H. the Princess Victoria. His appointment as chemist to the princess followed immediately after (1836), and when the medical staff of the Queen was published in the *Royal Gazette*, immediately after Her Majesty's accession in 1837, the name of Peter Squire appeared as Chemist in Ordinary on the establishment. When he retired from this post in 1877 he had completed his fortieth year of service.

In 1841 Mr. Squire commenced the long series of services rendered by him to the Pharmaceutical Society of Great Britain, he having been a member of the Committee to which the meeting at the Crown and Anchor entrusted the task of drawing up a constitution and framing bye-laws. This Committee carried on the business of the Society until the election of the first Council in 1842, among the members of which Mr. Squire was included. He took an active part in the organization of the Board of Examiners, and for twenty-seven years he occupied a seat upon it. When he retired from the Board in 1869 he was presented with an address, signed by every member of it, couched in the following terms:—

"The Board of Examiners desire to place on record their high appreciation of the valuable services rendered by their esteemed colleague Mr. Peter Squire in organizing and so ably carrying forward the important work of examination from the very first meeting of the Board in July, 1842, to the present time," etc.,—Dated June 11, 1869.

In 1849 Mr. Squire was elected President of the Pharmaceutical Society; and after an interval of twelve years he was again elected in two successive years. His exertions about this time, with others, to secure the exemption of pharmaceutical chemists from jury service cost him a severe illness. Mr. Squire continued a member of the Council until 1870. During his active connection with the Society he contributed a number of important papers to the evening meetings.

When the news arrived of painless operations being performed in America under the influence of ether, Mr. Squire constructed the apparatus by which the first capital operation was performed by Mr. Liston at the University College Hospital, which apparatus is now in the museum of that hospital. Mr. Squire assisted Dr. Stevens in his investigations on human blood, and he likewise assisted Dr. Marshall Hall in his experiments on the subject of the resuscitation of the apparently drowned (the so-called ready method).

Mr. Squire was a founder of the College of Chemistry, which formerly occupied the premises now used by the Medical Council. He was also one of the founders of the Royal Botanic Gardens in the Regent's Park, and a fellow of the Linnæan Society.

With regard to the works written by Mr. Squire the first to mention is 'The Three Pharmacopœias Compared' (1851). This work contained the entire contents of the London, Edinburgh and Dublin Pharmacopœias set side by side in three columns (Royal 8vo) in order to show the alarming differences in strength of preparations bearing the same name, and the danger of a prescription written in London being made up in Dublin, say twelve hours afterwards. Such a prescription might, in the case of acetum colchici for example, have three times the power the prescriber intended. A risk of this kind in days of railway travelling was considered a great evil and almost the first act of the Medical Council was to resolve upon having a National Pharmacopœia which should supersede those of London, Edinburgh and Dublin.

A committee for this purpose was appointed, and the Pharmaceutical Society was requested to send its delegate to be a member of the Committee, and Mr. Squire was chosen. Dr. Farre, Dr. Garrod and himself were to represent the London section of the Committee. Dr. Apjohn, Dr. Neligan and Dr. Aquilla Smith represented Dublin; and Dr. Christison, Dr. Maclagan and Dr. A. Wood represented Edinburgh. This Pharmacopœia was published in London in 1864.

Mr. Squire, believing that an International Pharmacopœia might some day be brought about, published what he called 'The Companion to the British Pharmacopœia' and in this he compared the formulæ of the British with similar preparations found in the Austrian, Belgian, French, Prussian and United States Pharmacopœias and also with the former Pharmacopœias of London, Edinburgh and Dublin.

The success of this book induced Mr. Squire to apply the same idea to the Pharmacopœias of the principal hospitals of London. He accordingly collected and published these, classifying their formulæ for ready comparison. This book was published under the title of 'The Pharmacopœias of the London Hospitals.'

As an instance of the activity of mind which Mr. Squire retained up to the very end of his long life, it may be mentioned that a few months before his death he was engaged in studying the best method of preserving the freshwater medusæ found in the "Victoria Regia tank" at the Botanical Gardens, and communicated the result of his investigations in a paper which was read (July 9, 1883) before the Royal Microscopical Society.

We understand that the primary cause of Mr. Squire's death was congestion of the lungs, resulting in exhaustion. The funeral will take place in Kensal Green Cemetery, on Saturday, the 12th inst., at two o'clock.

ANSWERS TO CORRESPONDENTS.

J. Strachan.—We should think the stronger the better.

An Apprentice.—The name is apparently a fancy one, and is probably not intended to favour the identification. If you will send a portion of the "root," we will try and find out something as to its origin.

Antiseptic.—We do not know the preparation. An analysis would furnish you with the information you require.

Pharmacist.—Although agreeing with much that is contained in your letter, we are not prepared, in face of the fact that a similar experiment to that suggested by you has been already tried in this country and failed, to undertake to recommend its repetition at present. At any rate it would be prudent to wait and see the result of the effort now being made on the other side of the Atlantic.

A Correspondent from Dufftown.—The growth consists of *Merulius lachrymans* and *Lentinus lepideus.*

"*Amicus.*"—Put half the yolk of one egg with the acetic acid and turpentine into a 6-oz. bottle; shake well at intervals three or four times.

Correspondence.

THE NEW PREMISES IN EDINBURGH.

Sir,—In reading over the report of the meeting of Council in the Journal of the 5th inst., I was very pleased to find the unanimity prevailing regarding the purchase of premises for the North British Branch in Edinburgh. The rooms at present are very good, but I feel sure that the Scotch members will be delighted to hear that scientific pharmacy is about to obtain "a habitation and a name" in the Scotch metropolis.

I do hope the membership will increase, and would suggest that a special donation might be asked from members of the trade in Scotland to defray part of the expense in fitting up the new premises.

What could be more delightful or profitable for country members than a stroll through the Pharmaceutical Society's premises when in Edinburgh? I hope some demonstration will take place at the opening and give the new premises a start.

ST. RULE.

THE POSITION OF PHARMACY.

Sir,—Mr. Hart tries to be witty at my expense. Well, I hope it pleases him, for it does not hurt me, and if he is happy I am content.

However, I am not going to descend to personalities either with him or any one else over this matter.

I entirely deny that there is any inconsistency between my first letter and any of the subsequent ones; what I wrote then I still maintain, and no one has yet attempted to dispute my statements or to deny their truth; whilst everybody who has written on the subject cries out against the Council with some pet grievance of his own, but leaves my allegations entirely unanswered.

I hope I am not so blinded by prejudice as not to see how much both pharmacists and non-pharmacists owe to the Society, nor so devoid of justice as to be unwilling to acknowledge it, and if I am in consequence to be charged with vacillation and inconsistency, I am well content to bear the imputation.

Cheetham Hill, Manchester. W. WILKINSON.

Sir,—The other evening, during the hour that intervenes between business and bed, I had been reading the correspondence which Messrs. Wilkinson and Co. have recently carried on in your columns, until wearied at last with the shop and all its belongings I laid down my Journal and took my Tennyson from his shelf. Instinctively I turned to that delicious picture of the lotus eaters, delicious indeed to a poor toiling druggist! and endeavoured to lap myself in its fancied Elysium. But your correspondents' baleful influence was strong upon me and would not be shaken off. The terrible pharmaceutical suggestions of the verse—

"And from the craggy ledge the poppy hangs in sleep"

completed the mischief, and from that point onwards Tennyson and Wilkinson, lotus land and the dispensing department, became inextricably mixed in my consciousness. I could not even recover myself to take in the loveliness of—

"The crisping ripples on the beach,
And tender curving lines of creamy spray."

But gradually I became more and more involved in confusions and uncertainties, until at length the words danced like demons over the page in the most fantastic combinations, and I read—or seemed to read—some such cross-bred doggerel as this—

"Let us swear an oath and keep it; let the Council find
We'll keep up no Society (whate'er the cause assigned)
While they live like gods together, careless of their kind.
For they sit and talk in London, and their napkins are unfurled
At their pharmaceutic banquets, and their lips are lightly curl'd,
Naturally, at us 'poor devils' in this lower world.
While they smile in secret, looking over wasted lands,
Stores and groceries, joint-stock companies, borough analysts' demands,
Doctors' raids, unscheduled patents, closing shops, and praying hands.
For they smile, they find a music, centred in a doleful song,
Steaming up, a lamentation, and an ancient tale of wrong;
Like a tale of little meaning, though the words are strong;
Chanted from an ill-used race of men who vilely toil,
Pass exams., yet unprotected after mickle moil
Spend fourteen hours a day 'dispensing' horse-balls, paints, and oil,
Till they smash, and so they're done for—some, 'tis whispered, bolt as well,
Others as assistants languish, and a few, oh! strange to tell,
Get a ten-pound note per annum from the Fund they helped to swell.
Surely 'tis a bitter ending, after all that went before,
Pounding pills, and spreading blisters, and 'the bums' when all is o'er;
Then, hark ye, brother pharmacists, let us subscribe no more!"

Here, sir, the climax of the absurdity (for which, believe me, your correspondence columns are alone to blame) awoke me; and I hastened to write out a cheque for a guinea in favour of Mr. Bremridge for fear I should longer forget that my annual subscription was overdue.

C. C. BELL.

THE ANTIPODES.

Sir,—Can any reader of the Journal furnish information as to the prospects of pharmacists at the antipodes? In view of the fact that the increase in the number of chemists on the register is out of all proportion to the increase of population, and with the "stores" spectre turning our dreams of success in business into dismal nightmares of anticipated failure, it appears to me that some of us, who are young and strong, cannot do better than take Lord Derby's advice, and, for the sake of our fellows as well as for our own sakes, try to find employment for our brains and muscles in another country. Two of us (both qualified, and with small capital), intend going to Australia or New Zealand in the autumn. But 12,000 miles is a long way to go "on spec." Perhaps some reader of the journal can tell us whether there is plenty of business to be done, and whether the remuneration is good. Is trade so very different to that in this country? Would it be better to take situations as assistants, or start at once on our own account?

Believing, Sir, that replies to these questions will be read with much interest by very many assistants, I ask with confidence that you will allow them to be inserted.

INQUIRENS.

EUCALYPTUS OIL.

Sir,—In a recent issue of the Journal I noticed a paragraph under "The Month" in which it is stated that eucalyptus oil of the kind that has been in the market for some years is obtained from *Eucalyptus globulus*; this is an error, and one that I have endeavoured to get the wholesale trade at all events to give up.

Eucalyptus oil was first distilled by Dr. Bosisto, of Melbourne, some twenty years ago, from the *Eucalyptus amygdalina*, which is as distinct from *E. Globulus* as *M. Piperita* is from *M. sativa*, and is an entirely different oil from that obtained from the *E. Globulus*.

The success which Dr. Bosisto's oil has met with has induced people, having no knowledge of the different kinds of *Eucalyptus*, or gum-trees as they are called in Australia, to distil any oil from the leaves gathered indiscriminately from one or any of the forty or more *Eucalypti* growing in the Australia bush, and consequently have obtained an oil totally different from Dr. Bosisto's.

Some two years ago Dr. Bosisto distilled an oil from *E. dumosa*, or, as it is known in Australia, the mallee scrub. This oil differs slightly from the *amygdalina* in perfume, but Dr. Bosisto is of opinion that medicinally its properties are the same.

The *E. Globulus* is the tree that has a great power of absorbing moisture from the earth and passing it off by its leaves into the air, and has hence been largely planted in malarial districts. The introduction of this tree into Europe (at Rome, etc.) has doubtless been the source of the constant confusion as to the origin of Dr. Bosisto's well-known oil.

82, *Bishopsgate Street, E.C.* E. H. GRIMWADE.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Schacht, Moore, Howe, Jumbo, Assistant.

METACETALDEHYDE.*

(METALDEHYDE.)

BY WYNDHAM R. DUNSTAN,

Assistant Lecturer in Chemistry and Physics to the Pharmaceutical Society and Demonstrator of Practical Chemistry in the School of Pharmacy.

My attention was recently directed by the excellent Curator of the Pharmaceutical Society's Museum, Mr. Holmes, to some crystals which had been found in a bottle of acetaldehyde. They had been presented to the Museum by Messrs. Morson, and were supposed to be aldehyde-ammonia. The white opaque crystals, which formed fairly well-defined quadratic prisms, were quite permanent in the air and had no odour; they were easily powdered, and the powder at first emitted an odour which somewhat recalled peppermint, but after being exposed to the air for some hours was quite odourless. When heated the crystals sublimed near 100° C. without previously melting, forming a flock-like network of needle-shaped crystals, the condensation of the vapour taking place but a very short space above the source of heat; in fact, when a crystal is heated on platinum foil it burns with a non-luminous flame, and if the foil be quickly withdrawn from the source of heat, and the flame blown out, the vapour at once condenses upon the remaining portion of the crystal, forming a beautiful coating of silky needles. The crystals were insoluble in cold and hot water, and also in cold alcohol. Boiling alcohol dissolved them, and on cooling the solution, fine needle-shaped crystals were deposited. The crystals were also soluble in boiling ether and chloroform. Sulphuric, nitric and hydrochloric acids had no effect upon the substance in the cold. Warm sulphuric acid dissolved the substance, at the same time evolving a vapour smelling like acetaldehyde. Warm nitric acid powerfully oxidized the body with copious evolution of nitrous fumes; acetic acid was found in the resulting liquid. Hot hydrochloric acid also dissolved the crystals. The crystals contained no nitrogen. The combustion of the body with lead chromate yielded the following results:—

	Found. I.	Found. II.		Calculated for C_2H_4O.
C. .	53·4	54·3	C. .	54·54
H. .	9·3	10·0	H. .	9·09
O. .	37·3	35·7	O. .	36·37
	100·0	100·0		100·00

These figures, taken in conjunction with the physical and chemical properties that have been described, indicated that the crystals were *metacetaldehyde*† $(C_2H_4O)_n$, the solid polymer of ordinary aldehyde and the congener of paracetaldehyde, which has so lately been introduced into medicine as a hypnotic. When metacetaldehyde is heated it partially dissociates into acetaldehyde, and for this reason it has not been possible to determine its molecular weight and hence its two-volume formula is unknown. Judging from physical properties the molecular weight is probably higher than that of paracetaldehyde $(C_6H_{12}O_3)$.

In addition to the reactions already mentioned, the following have been observed, and, as far as I am aware, have not been noticed by previous experimenters—Liebig, Fehling, Weidenbusch, Kekulé and Zincke, Pinner and Krämer. Metacetaldehyde in alcoholic solution does not reduce an ammoniacal solution of silver nitrate and is thus distinguished from acetaldehyde.

Metacetaldehyde is very slowly acted upon by a hot strong solution of potash, yielding "aldehyde resin." When a mere trace of metacetaldehyde is brought in contact with phenol dissolved in excess of sulphuric acid (phenol sulphonic acid) a fine scarlet colour is produced, which changes to a dark red when the mixture is warmed. The reaction is extremely delicate and is also given by acetaldehyde. Many other aldehydes (benzoic, cinnamic, cumic, formic, etc.) give this reaction with phenol sulphonic acid in a more or less marked degree. Oil of cinnamon (cinnamic aldehyde), in very minute quantity, gives a deep scarlet colour, which changes through deep red and violet to a greenish blue. When the crystals of metacetaldehyde are heated in a sealed tube to 130° C. for a few hours a liquid is formed which mainly consists of acetaldehyde. Metacetaldehyde is dissolved by boiling paracetaldehyde and to less extent by boiling acetaldehyde. When these solutions are cooled the metacetaldehyde is deposited in needles. Hot hydrochloric acid is capable of dissolving a large quantity of metacetaldehyde which is thereby depolymerized and converted into acetaldehyde. When the acid liquid is diluted with water and neutralized, it gives the reactions of acetaldehyde with great distinctness. This is the readiest method of depolymerizing metacetaldehyde.

I have prepared metacetaldehyde by the action of sulphurous acid upon acetaldehyde at 0° C., and have found that the crystalline body thus obtained agrees in its properties with the crystals now under consideration. The formation of these crystals in the bottle of aldehyde was in all probability induced by the use of calcium chloride for dehydrating the original aldehyde. This substance is known to exert a polymerizing action upon acetaldehyde; in fact, when a piece of calcium chloride is placed in acetaldehyde it becomes covered with crystals of metacetaldehyde. When metacetaldehyde is slowly deposited at normal temperatures from a solution in ordinary aldehyde (acetaldehyde) it appears to form quadratic prisms, but when produced by the action of sulphuric acid at 0° C. it is deposited in needles. It has already been noticed that the quadratic prisms are resolved into needles when sublimed, or when dissolved in boiling alcohol and the solution cooled.

The physiological action of metacetaldehyde has not yet been studied. It would, however, seem worth while to investigate it, for the substance can easily be obtained in a state of great purity, and has no unpleasant taste; in fact, is practically tasteless. If it should be found to have a powerful hypnotic action metacetaldehyde will probably supersede both chloral and paracetaldehyde in medical practice. I found that no hypnotic effect ensued from the administration of about seven grains of the substance, but intense salivation was produced.

My best thanks are due to Mr. Walter H. Ince for his assistance, especially in preparing some of the experiments to illustrate this report.

* Report upon Organic Chemistry. Read at a Meeting of the School of Pharmacy Students' Association, March 27, 1884.

† The polymers of acetaldehyde are commonly termed paraldehyde and metaldehyde, but as aldehydes other than acetaldehyde yield similar compounds, these bodies are more appropriately termed paracetaldehyde and metacetaldehyde, indicating their formation from acetic aldehyde or acetaldehyde.

THE MATERIA MEDICA OF THE NEW PHARMACOPÉE FRANÇAISE.

(*Continued from page* 758.)

C.

The following are now omitted:—Caïlcedra bark (*Khaya senegalensis*); Caïnca root (*Chiococca anguifuga*, Mart.); *Anthemis Cotula*, *Camphorosma monspeliaca*, L.; Cassia flowers and oil of cassia; the barks of *Cinnamomum Culilawan* and *Dicypellium caryophyllatum*; Safflower flowers and fruit; *Nepeta Cataria*, L.; Citron fruit and oil; Greater Centaury (*Centaurea Centaurium*, L.); Sweet Chervil; Greater Celandine; Woodlice; the root of *Cyclamen europæum*, and Cypress cones (*Cupressus sempervirens*, L.). The synonym for Capsicum, "Corail des Jardins," is also omitted as a cross reference.

Alterations have been made in the following instances:—

Cachou de Pegu or Caschutie.—The official catechu is now limited to the extract of *Acacia Catechu*, W., and *A. Suma*, Kurz.

Cade, Huile de.—The botanical source is still given as *Juniperus Oxycedrus*, L., although, according to the authors of 'Pharmacographia,' there is no proof that it is now yielded by that species, the crystals found in the tar obtained from that plant, being absent in the commercial article.

Cajeput.—*Melaleuca Leucadendron*, L., is now adopted as the botanical name, instead of *M. minor*.

Camphre du Japon is now removed to the second class of chemical preparations, probably because the drug is always used in the refined, and not in the crude state.

Caoutchouc is now described as being obtained from *Castilloa elastica*, Cerv., *Hevea guayensis*, *H. Spruceana*, *H. brasiliensis*, some species of *Moraceæ*, and American or African Apocynaceous species, belonging to the genera *Hancornia* and *Vahea*.

Capillaire.—The directions for distinguishing between the Capillaire du Canada (*Adiantum pedatum*, L.) and Capillaire du Montpellier (*A. Capillus-Veneris*, L., are now omitted.

Cevadille.—The seed as well as the fruit are now official. *Schœnocaulon officinale*, A. Gray, is adopted as the botanical name of the plant.

Chene.—The bark of *Quercus Ilex*, L., is now official, as well as that of *Q. pedunculata*.

Cochenille.—The word "femelle" is omitted.

Colchique.—Colchicum corm was described in the last edition as a "tubercule bulbiforme;" now it is described as a "bulbe," a term not usually applied to colchicum in this country.

Colombo.—*Chasmanthera palmata*, H. Bn., is now adopted as the botanical name for the plant, but *Jateorhiza palmata*, Miers, is given as a synonym.

Colophone or Arcanson.—This is not now limited to the resin obtained from *Pinus maritima*, but is described as the product of different species of Coniferæ.

Concombre sauvage.—*Ecbalium Elaterium*, A. Rich., is given as the name of the plant, and *Momordica Elaterium*, L., as a synonym.

Copahu.—*Copaifera coriacea*, Mart., is added to the species mentioned in the last edition as yielding the drug.

Courge potiron.—The seeds are now only to be obtained from *Cucurbita maxima*, Duch.

Cousso.—*Hagenia abyssinica*, Lam., is now adopted as the botanical name, and Bruce's name, *Banksia abyssinica*, dropped.

Curari.—The poison is now said to be principally obtained from *S. Castelnœana*, Wedd., the production of the region of the Upper Amazon. (See *Pharmaceutical Journal*, [3], xi., p. 492.)

Curcuma long et rond.—*C. longa*, L., is now given as the botanical name, in place of *C. tinctoria*, Guib.

The drugs marked with an asterisk under "C." are Catechu, Roman Camomile, *Canne de Provence* rhizome, (*Arundo donax*, L.), Cinnamon, Cantharides, Canadian Maidenhair, Malabar Cardamoms, Carragheen, Cassia fistula, Hartshorn, Castoreum, lesser Centaury (*Erythræa Centaurium*, L.), *Chardon bénit* (*Centaurea benedicta*, L.), Chicory root, Hemlock, Wax, Calumba, Colophony, Colocynth, *Consoude grande* (*Symphytum officinale*, L.), Copaiba, *Coquelicot* (*Papaver Rhœas*, L.), Coriander, Cousso, Croton seeds, Cubebs and Cummin.

D.

The only alterations under "D." are the introduction of dita bark and directions under digitalis for distinguishing it from the leaf of *Inula Conyza*. The tests given are that the lateral veins are at an oblique angle to the midrib in *Digitalis*, and that the infusion treated with ammonia does not give the green coloration characteristic of the infusion of *Inula Conyza*.

E.

The following are now omitted:—*Veratrum album*, Estragon (*Artemisia Dracunculus*, L.), *Euphrasia officinalis*, L. *Helleborus niger* and *H. viridis*, are now placed under "H," as *Hellebore blanc* and *Hellebore noir*.

Elemi.—Other varieties of Elemi beside the Brazilian are now admitted in the following terms:—"Résine extraite de diverses espèces de Burseracées d'Amérique et de Manille, principalement (?) du *Canarium commune*, L." This sentence, to say the least, is very ambiguous, and the last four words might well have been omitted.

Encens, Oliban, is now mentioned under the first of these names, and is correctly attributed to *Boswellia Carterii* and *B. Bhau-dajiana*, Birdw., although both the specific names are printed incorrectly.

Eponge fine.—*Spongia usitatissima* as well as *S. officinalis* is now given as a source of sponge.

Erysimum, Vélar, Tortelle, Herbe aux chantres (*Sisymbrium officinale*, DC.), is now given under the first instead of the second name. Here, again, a printers' error has not been corrected in "Sysimbrium."

Escargot or Limacon des Vignes.—The remark that *Helix aspersa* and *H. vermiculata* are used in the south is now omitted.

Euphorbe (Gomme resine d') is now referred to *Euphorbia resinifera*, Berg.

The only addition under "E" is the *Eucalyptus globulus*, Lab., of which the leaves only are official.

F.

The only alterations under this head are the addition of potato starch, and the change of the name of *Ignatia amara* to *Strychnos Ignatii*, Benth., and that of the ash tree from Frêne élevé to Frêne.

G.

The articles omitted are Chinese galls, Gambier, Genêt purgatif (*Genista purgans*, L., and *G. tinctoria*, L.), Ginseng and Grenouille (*Rana esculenta*, L.). Gélatine animale has been removed to the Pharmacie Chimique division, and Graisse de porc to Pharmacie Galénique, where it may be found under the name of Axonge.

GALANGA OFFICINAL; GALANGA DE LA CHINE, PETIT ET MOYEN.—This rhizome is now rightly referred to *Alpinia officinarum*, Hance.

GALBANUM.—This is now stated to be probably the product of *Ferula galbaniflua*, Boiss. et Buhse, and *F. rubricaulis*, Boiss. The distinction of the drug as a dry and a soft galbanum is no longer made, nor is any description of its appearance given. This, however, is perhaps of little importance, as a process for its purification is given in the section devoted to Pharmacie Galenique, and a uniform consistence can therefore be obtained.

GALIPOT.—*Pinus Pinaster*, Sol., is the name now adopted in preference to that of *Pinus maritima*.

GALLE DE CHENE D'ALEP OU NOIX DE GALLE D'ALEP.—The oak yielding these galls is now made a variety; thus, *Quercus lusitanica*, Webb., var. *infectoria*.

GAYAC.—Guaiacum is now referred to *G. sanctum*, L., as well as *G. officinale*, L.

GOMME ADRAGANTE.—Tragacanth is now described as being derived from various species ot *Astragalus*.

GOMME AMMONIAQUE.—*Peucedanum Ammoniacum*, R. Br., is given as a synonym of *Dorema ammoniacum*.

GOMME ARABIQUE VRAIE.—Is described as being friable and soluble in water. It is now referred to *Acacia Senegal*, W., and *Acacia Arabica*, W. Both of these species yield a gum, however, which can hardly be said to be friable, being usually hard and clear internally.

GOMME GOUTTE.—This is now correctly referred to *Garcinia Hanburii*, Hook.

GOMME DU SÉNÉGAL.—This is stated to give a viscous solution and to be obtained from several species of acacia, chiefly *A. Senegal*, W., *A. Seyal*, Del., and *A. Arabica*, W.

GRENADIER.—The remarks in the last edition under this drug are now omitted.

GUTTA PERCHA.—This is now attributed to *Dichopsis Gutta*, Thw., *Sapota Mulleri*, and other trees of the Sapotaceous family. The product of the last-named tree is known in commerce as Chicle gum. Dr. Beauvisage has recently shown that some of the gutta percha of commerce is produced by *Dichopsis Krautziana*, a name which might well have replaced that of *S. Mulleri*.

The only addition under "G" is Gland doux, the sweet acorn of *Quercus Ballota*, L.

H.

HOUX COMMUN (*Ilex aquifolium*), Huile de palme, and Huitre commune, L., are now omitted, and the only addition is *Hydrocotyle Asiatica*.

HYSSOPE is now referred to *Hyssopus officinalis*.

I.

INDIGO and the rhizome of *Iris fœtidissima*, L., are omitted. Ipecacuanha and iris root are marked with an asterisk.

ICTHOCOLLE OU COLLE DE POISSON.—*Acipenser ruthenus* and *A. vulgaris* are now given in addition to *A. Huso* as sources of isinglass, and all mention of E. Indian and S. American isinglass is omitted.

IRIS DE FLORENCE.—*Iris germanica* and *I. pallida* and "other species" are now mentioned as sources of orris root.

Peucedanum Ostruthium, Koch., is the name now accepted for *Imperatoire*, and *Uragoga Ipecacuanha*, H. Bn., is mentioned as a synonym for *Cephaëlis Ipecacuanha*.

J.

JACÉE DES PRÉS (*Centaurea Jacea*, L.) and JOUBARBE DES TOITS (*Sempervivum tectorum*, L.) are now omitted and Jaborandi has been added.

JALAP and *Hyoscyamus niger* are marked with an asterisk.

JABORANDI.—The leaves of *Pilocarpus pennatifolius*, Lem., and *P. Selloanus*, Eng., and allied species are official. As the leaves of *P. Selloanus* have been stated to contain less alkaloid than those of *P. pennatifolius*, and there exists no definite information of the strength of "allied species," the preparations (extrait, tisane, teinture, etc.) made from the drug are likely to vary considerably in strength.

JUSQUIAME.—The remark that the only henbane seed now to be found in commerce is that of *Hyoscyamus albus* is omitted.

K.

KERMÈS ANIMAL is omitted.

L.

LADANUM, LEQUE LIERRE COMMUN (Ivy) and the fruit and oils of Limes Lupin (*L. albus*) are omitted.

LACTUCARIUM is now acknowledged as being derived from several species, *L. virosa*, L., *L. sativa*, L., *L. Scariola*, L.

LAURIER-CERISE is now referred to *Prunus Laurocerasus*, DC.

M.

The following articles are omitted:—Malabathrum, Mandragore, Maniguette or graine de paradis, Marronier de l'Inde, Mélèze, Melisse de Moldavie (*Dracocephalum Moldavicum*, L.), Méum and Myrobalan citrin.

Those marked with an asterisk are Manne, Mauve (*Malva sylvestris*, L.), Melilot officinal, Melisse officinale, Menthe poivrée, Menyanthe, Mercuriale annuelle, Miel, Morelle (*Solanum nigrum*, L.), Mousse de Corse (*Alsidium Helminthocorton*, Kutz), Moutarde noir, Musc and Myrrhe.

The following alterations have been made:—

MARJOLAINE.—*O. majoranoides*, Willd., is no longer official, but only *O. Majorana*, L.

MAUVE.—*Malva glabra*, Desr., is now omitted, and *M. sylvestris*, L., is alone official under this name.

MAUVE PETITE.—This is now the official name for *Malva rotundifolia*, L., instead of Mauve à feuilles rondes, as in the last edition.

MENTHE VERTE.—*Mentha viridis* apparently replaces *M. crispa*, L., which is now omitted.

MOUSSE DE CORSE.—This is now referred to *Alsidium* (*Gigartina*) *Helminthocorton*, Lam.

MOUTARDE NOIR.—This is now referred to *Brassica nigra*, L., while Moutarde blanche is still referred to the genus *Sinapis*, and *S. nigra*, L., given as a synonym.

MUGUET.—The entire plant as well as the flower of the lily of the valley is now official.

MURE is now the official name for Mulberry, instead of Murier noir.

MYRRHE.—This is described as a gum resin exuding from different species of *Balsamodendron*, especially from *B. opobalsamum*, Kth. This is not correct, *B. opobalsamum* yields Balm of Gilead, as stated in the last edition of the work. See also *Pharm. Journ.*, [3], vol. ix., p. 893.

(*To be continued.*)

UNOFFICIAL INDIGENOUS MEDICINAL PLANTS.*

BY E. J. EASTES.

The object of this paper is not to describe some of those plants which, although excluded from our Pharmacopœias, are yet commonly employed by our regular practitioners, but it is intended to give a brief sketch of the more important of those plants which may be called domestic remedies, being such as are still in common use in country districts, and are still sold in towns and cities by herbalists, and medico-botanists, *i.e.*, dealers in and prescribers of both British and American herbs.

It is a fact that these common herbs have a great reputation with many people as being the best remedies for numerous ailments, and as a consequence the demand for them is also great, and the public must go to shops of some description to obtain them. As is well known not one chemist in a hundred keeps in stock such articles as comfrey, burdock, buckbean, yarrow, tansy, etc., therefore the people who use them must go to the herbalist for them. It seems to me that chemists, by so completely ignoring this branch of materia medica, are, in country districts at least, deliberately turning away many scores of customers, and that at a time when there is a universal cry about trade going down, and profits being cut excessively fine. For these things would bring a profit of at least fifty per cent., and customers once obtained would be almost certain to come again to the same shop. Looking at it from a higher standpoint also, many of these plants possess considerable activity, such as bryony, tansy, and purging flax, and although probably very useful if taken in proper quantities, in some cases an overdose might, and no doubt frequently does, produce unlooked-for and perhaps dangerous results. Therefore, who so proper to deal with them as the registered chemist, who has been examined in the very branches of science which bear upon the recognition, properties, and appearances of drugs; and who is expected to be able to manifest in his examination a knowledge of our indigenous medicinal plants.

If any of the members of this Association should ever be located in a country pharmacy, they will in all probability be asked for these articles. Certainly in a French pharmacy they would be expected to be familiar with their appearance and properties, a large number being included in the present French Codex.

I thought, therefore, that perhaps it might be interesting to show specimens and give brief descriptions of a few of the more important of them. For certainly this branch of our business seems to be worth the trouble of cultivating.

The specimens on the table were obtained from a genuine herbalist's shop not a hundred miles from Bloomsbury Square, and may, I think, be taken as fair samples of the drugs as usually sold. It was suggested to me by Professor Bentley that it would be interesting also to try and find out if these herbalists sold any of the more active poisonous drugs, such as henbane, savin, foxglove, lobelia, which might be used for unlawful purposes. But on asking for such articles the proprietor of the shop was most careful in assuring me he never sold anything that was at all poisonous. But I think his statements must be received with caution, for I noticed in a corner a bill stating that stramonium was sold for smoking at 3*d*. per ounce. On asking also for henbane seeds he told me he had none, although he did occasionally keep them, but never at any time sold them except in very small quantities, certainly not enough to do anyone any harm. He evidently rather mistrusted me, for a couple of days later I sent a friend to the same shop, who readily obtained some with the following directions for their use as a remedy for toothache:—To place some on a hot shovel, that a white smoke would arise, over which the patient was to hold his open mouth. The package was labelled, "Henbane seed, poison."

Of the following plants described, the medical and economic purposes for which they are at present employed are given on the authority of Sowerby's 'British Botany,' and Barton and Castle's 'British Flora Medica.'

Linum Catharticum, purging flax, mill mountain.—First mentioned by Thalius in the 16th century. Whole plant used. Inodorous. Taste very bitter. Active principle probably a bitter extractive. By the concurrent testimony of nearly all the old writers this plant is a safe and effectual cathartic. The infusion is said to be more purgative than senna. But its action at times is somewhat uncertain. It is commonly used in Wales and Scotland. It is even now retained in some Pharmacopœias.

In some parts of the country it is boiled in ale and the decoction given for rheumatism. The usual dose is 1 drachm of the dried plant, or a handful of the fresh herb infused in water or whey.

Gerard relates how he came to be acquainted with the plant while in company with Dr. Lake, afterwards Bishop of Bath and Wells, and "who always used this herbe for his purge after the said manner as his man affirmed; putting a handful of Mil Mountain into a small tunne or pipkin of a pinte, filled with white wine, and setting it on the embers to infuse all night, then drinking the wine in the morning, fasting."

Agrimonia Eupatoria.—In Barton and Castle's 'British Flora Medica' the specific name is said to be derived from the Greek "hepar," the liver, from its value in diseases of that organ, but this derivation seems far from satisfactory. Also called "philanthropos," on account of its beneficent and valuable properties. It is official in the French Codex. The plant has a faint agreeable odour which is nearly lost on drying. The flowers are said to smell like apricots. It contains a great deal of astringent matter to which probably most of its properties are due. An infusion is considered very beneficial in jaundice and liver complaints and dropsy. Also used as a diuretic and vermifuge. Has been used in North America with great success in fevers. Also considered a purifier of the blood in cutaneous diseases and eruptions. The infusion forms a very good gargle for sore throat. An old writer recommends agrimony to be taken with a mixture of pounded frogs and human blood as a remedy for internal bleeding. A decoction made with wine and drunk, was reputed an antidote for the bites of serpents.

Culpepper says, "the leaves and seeds being stamped with old swine's grease, and outwardly applied, helpeth old sores, cancers, and inveterate ulcers, and draweth forth thorns, splinters of wood, nails, or any other such thing gotten into the flesh."

Agrimony has been employed for the tanning of leather. It also furnishes a good yellow dye.

Bryonia Dioica, white bryony.—Official in the French and United States Pharmacopœias. The dried root, according to the herbalist from whom I obtained it, is a valuable tonic and stomachic, similar to gentian. He said working men bought much of it to chew whilst they were at work. But I think he must certainly be in error, for all the works to which I have referred give its properties as being acrid and purgative, and in large doses emetic and poisonous. From its great activity when fresh it is called in France the "devil's turnip." Pereira mentions a case of poisoning by it, the symptoms of which were mistaken for those of cholera by the practitioner who attended the case. Both this plant and the black bryony, *Tamus communis*, contain an active alkaloid, bryonin, intensely bitter, soluble in water and alcohol. Twenty-two grains killed a rabbit in ten hours, 34 grains injected under the skin of a dog killed it in fifty-eight hours. The root of white bryony is used in Germany and Sweden as a purgative, and also as a vermifuge. With regard to this latter use there are some extraordinary stories on record of its efficacy in expelling

* Read at a meeting of the School of Pharmacy Students' Association, March 27, 1884.

toads and frogs and several nondescript animals from the abdomen. The fresh root is used externally as an application to bruises. Withering says a decoction of the fresh root is the best purge for horned cattle.

Gerard says the bruised root mixed with sulphur and vinegar is used for rubbing on the face to remove freckles and spots. The berries are poisonous and emetic. The young spring shoots when boiled have been eaten as a vegetable. The forked root is sometimes offered by herb gatherers around London as mandrake root.

Tamus communis.—Interesting as being the only British illustration of the Yam family, yams forming an important article of food in all tropical countries.

The large fleshy root or rhizome is the part used. It possesses very similar properties to those of white bryony. My herbalist said he had a great demand for it, and always kept it in the fresh and moist state. It was, he said, a most valuable application to bruises. He was quite celebrated for the number of black eyes he had cured with it. As his shop is in close proximity to Seven Dials, I have not the least doubt of the accuracy of that statement. The manner of using is to scrape the fresh root into a pulp, and apply as a poultice or plaister. The root of Solomon's seal, *Polygonatum officinale*, is also used for the same purpose, but more rarely, fresh raw beef being a common substitute. The young shoots of black bryony and other species of *Tamus*, when well boiled, are said to greatly resemble asparagus. Cooked in this manner with oil and salt they are much eaten by the Moors. The root taken internally is acrid and cathartic; it contains also much starch.

Sanicula Europœa, Wood Sanicle. — Although the word Sanicle has now come to mean something curative, it is not derived from the Latin "sanare" to heal, but from St. Nicholas or St. Nickel. There is a legend of this saint having interceded with heaven in favour of two children, whom an innkeeper had murdered and pickled in a pork-tub; and he obtained their restoration to life and health. No wonder, therefore, that the old herbalists so vaunt the virtue of this plant, dedicated to him, as a healing agent. In the middle ages there were many proverbial sayings extolling its virtues as "He who has bugle and sanicle makes a joke of the surgeons," or "He who keeps sanicle has no business with a doctor." The leaves are the part usually employed, but the whole herb is frequently used. The taste is very harsh and bitter. Sir James Smith entertained the idea that it partook of the poisonous acridity which is so frequent in umbelliferous plants.

It is commonly considered a very excellent remedy for internal bleeding. The juice or decoction is applied externally for the cure of ulcers and removal of tumours. Gerard says, "it makes whole and sound all wounds and hurts, both inward and outward."

Galium aparine, cleavers, clivers, goose-grass, catchweed.—Generic name from Greek "gala," milk, one of the species, *G. verum*, having been employed to curdle milk. Adrianus Junius alludes to it under the name of galium. The French name is "caille-lait," meaning curdle-milk. Its specific name aparine is from Latin "apairo," to lay hold of, because of its hooked bristles which attach themselves to passing objects. Young geese are extremely fond of it, hence the name goose-grass. The plants of this family are called bedstraws, from our ancestors having used their stems to stuff their beds with.

Properties.—Aperient, diuretic, antiscorbutic. Principally employed as a so-called spring medicine for purifying the blood. Has also been used in dropsy. As an outward application it was considered of the greatest value for the cure of cancers, scrofulous and scorbutic ulcers, the inspissated juice being used for that purpose. It used to be taken as a decoction to prevent persons from growing corpulent (perhaps it is an ingredient in Allen's anti-fat!) It was once thought to be a remedy for the bites of adders and poisonous spiders.

The roasted seeds have been employed as a substitute for coffee, which belongs to the same natural order. The madder belongs to the same order, and like that plant, the root of *Galium aparine* is said to furnish a red dye. Small birds that feed on it are said to have their bones tinged with red from this reason.

Artemisia Absinthium. — Wormwood. — The dried flowering tops are official in U. S. Pharmacopœia and the French Codex. Taste persistently bitter. Odour, strong and aromatic; reported to drive away fleas and other insects. Contains 1·5 per cent. volatile oil, isomeric with camphor, bitter, resinous and extractive matter, and a peculiar neutral principle called "absinthin." This is the essential bitter constituent of the plant. Wormwood is used as an anthelminthic and aromatic tonic; in the green state steeped in vinegar as a fomentation for bruises and sprains. Much employed in France in the preparation of the liqueur known as absinthe, which is very largely consumed in that country. In large doses wormwood produces headache, giddiness, and narcotic effects due to the volatile oil; in the lower animals it causes death. The salt obtained by lixiviating and evaporating the ashes of the plant, formerly much used and highly celebrated by the name of salt of wormwood, is merely K_2CO_3.

Culpepper's remarks on this herb are somewhat curious, and serve as an illustration of the absurd way in which he ascribes the virtues of plants to planetary and astrological influences. He says: "Wormwood is an herb of Mars. It causeth an appetite for meat, because Mars ruleth the attractive faculty in man. The sun never shone upon a better herb for the yellow jaundice than this. Wormwood, being an herb of Mars, is a present remedy for the biting of rats and mice. Mushrooms are under the dominion of Saturn; if any have poisoned himself by eating them, wormwood, an herb of Mars, cures him, because Mars is exalted in Capricorn, the the house of Saturn, and this it doth by sympathy. Suppose a man be bitten or stung by a creature, as a wasp, a hornet, a scorpion, wormwood, an herb of Mars, gives you a present cure. Mix a little with your ink, and neither rats nor mice will touch the paper that is written with it. Moths are under the dominion of Mars, his herb wormwood being laid among clothes will hinder moths from hurting them. The right eye of a man and the left eye of a woman the sun claims dominion over; the left eye of a man and the right eye of a woman are the privilege of the moon: wormwood, an herb of Mars, cures both. A draught of wormwood beer, taken every morning, is a certain remedy for a stinking breath." This is a sample of the medical treatises of our forefathers. Gerard also mentions that wormwood is an antidote for the poison of mushrooms, toadstools, and hemlock, and a remedy for the bite of the shrew mouse and sea-dragon.

Artemisia vulgaris, Mugwort.—Name derived from maggot wort, being sometimes used as a vermifuge. Before the introduction of hops it was much used for infusing in beer; some suppose the word mugwort formerly bore allusion to that use. The fresh flowering tops, when rubbed, have a fragrant and aromatic odour. The taste is sweetish and slightly bitter. An infusion is considered a good tonic, and is sometimes used as a remedy for intermittent fevers. It has also been recommended in epilepsy and convulsions. But its principal use is as a fomentation and emmenagogue. The powder of the dried leaves taken in wine is said to be a most speedy and certain cure for sciatica. A decoction applied outwardly is also used for the same purpose. Gerard and others recommend it as the best antidote for opium. The flesh of poultry and geese is said to be rendered more tender and savoury by being stuffed with this herb. The ancients used it for fattening animals. Pliny says the sheep of Pontus became very fat and were always without gall after eating this plant. He also remarks that if a traveller tie this herb around him he will feel no weariness, be hurt by no poison, nor by any wild beast.

Tanacetum vulgare, Tansy.—Name derived from St. Athanasius. Official in the U.S. Pharmacopœia and French Codex. Possesses similar properties to the two plants last mentioned. Resembles wormwood somewhat in odour and taste. Employed as an anthelminthic, tonic, stimulant, and blood purifier. In Gerard's time it was a common custom in the spring season to make cakes of the young leaves fried with eggs, and these were eaten with the notion that they purged the body of its foul humours. He also says the root preserved with sugar is an especial remedy against the gout, if every day, for a certain space, a reasonable quantity thereof be eaten fasting. According to Withering, if meat be rubbed with tansy leaves it is effectually preserved from the attacks of the flesh fly. It is also reputed to drive away insects from a bed in which it is laid. Was formerly much eaten in Lent as the representative of the bitter herbs commanded to be eaten with the Paschal lamb. Dr. Threlkeld relates the case of a soldier at Montpelier, who was cured of an obstinate dropsy by a decoction of tansy alone. In the *Pharmaceutical Journal* ([3], ii.) tanacetic acid is mentioned as a vermifuge, and substituted for santonin. It has a sharp bitter taste, insoluble in water, soluble in alcohol and ether. Forms crystallizable salts with bases. The volatile oil of tansy is said to be poisonous. In the *American Journal of Pharmacy* for 1882 there is a full analysis of tansy by O. Leppig. He gives the active bitter principle as tanacetin ($C_{11}H_{16}O_4$), which exists in the plant combined with tannic acid. He gives various reactions and tests by which it may be detected.

Chrysanthemum Parthenium, Feverfew.—So called from its supposed febrifuge qualities (Prior). Sometimes called feather few from confusion of name with feather foil. Official in the French Codex. The whole plant has a strong odour, somewhat resembling chamomile or wormwood, but which is partially lost on drying, and a bitter taste. It contains a small quantity of resin combined with a bitter mucilage, and a bluish volatile oil, which may be separated by distillation with water. Its properties are considered to be tonic, stimulant, sudorific, diuretic, emmenagogue, and anti-hysteric. Was once much used in ague and intermittent fevers. Gerard says:—"It is used both in drinks, and bound to the wrists with bay salt, and the powder of glass stamped together, as a most singular experiment against the ague." Principally employed now to drive cold out of the system by promoting perspiration; and as an emmenagogue, etc., in the same way as pennyroyal. Has also been recommended as a vermifuge. Externally a decoction has been employed in fomentations. It was said by the old herbalists to be good for vertigo or swimming of the head, and for such as be melancholy, sad, pensive, and without speech. Its odour is said to be particularly disagreeable to bees, and that these insects may be easily kept at a distance by carrying a handful of the flower heads.

Achillea Millefolium, Yarrow, Milfoil, Nose Bleed.—Generic name from the Greek warrior, Achilles, who is said to have discovered its virtues, and by this plant healed the wounds of his companions in arms. Called nose bleed, because country girls tickle the inside of their nostrils with a leaf of this plant, saying—

"Yarroway yarrow, bear a white blow,
If my love love me, my nose will bleed now."

Known also as "old man's pepper," from the pungent taste of its foliage. The leaves and flowering tops have a fragrant aromatic odour; they are official in the French Codex. It is principally used by herbalists for the cure of colds. I am told the patient is given a large quantity of yarrow tea to drink and is then put to bed. Profuse perspiration sets in, and after a night's rest the cold is said to be entirely driven out. An old quaker who made some prentension to medical skill was asked the best thing for a cold, he said "Take a pint of yarrow tea made strong on going to bed, put a hot brick at thy feet wrapped in a cloth wet with vinegar, and thou wilt surely be well in the morning." He was then asked for a cure for rheumatism, "Take a pint of yarrow tea made strong on goiog to bed and put a hot brick at thy feet wrapped in a cloth wet with vinegar and thou wilt be well in the morning." On being asked the best thing for worms in children, he said "Take a pint of yarrow tea made strong on going to bed, put a hot brick at thy feet, etc., etc." And for every disease that could be brought to mind he gave the same answer. Yarrow is much used in Norway for rheumatism. The Swedes infuse the flowering tops in beer to increase its intoxicating qualities. Has also been used as a styptic and vulnerary; a decoction as an anodyne fomentation. The leaves are chewed as a remedy for toothache. There is an ancient charm for the cure of tertian agues with yarrow. A leaf is to be pulled off with the left hand, pronouncing at the same time the sick man's name and this leaf is to be taken.

Arctium Lappa. Burdock, bur, or clot bur; official in the U.S. and French Pharmacopœias. The appearance of the involucres is well known. Country boys use them for catching bats by throwing them in the way of their flight. The bats entangle their membranous wings in the hooked bristles, and are thus brought to the ground. Virgil recommends it to be extirpated from the meadows in which sheep are fed, as it lessens the quality of their wool. The root is much used in disorders of the skin, being diaphoretic, tonic, and slightly purgative. Has also been used in dropsy, rheumatism, bladder complaints, and scrofula. It is thought to resemble sarsaparilla in its mode of action, and, like it, is used for purifying the blood. Recently recommended in Squibb's 'Ephemeris' as a remedy in certain skin disease. Some old writers considered it a specific in gout. The scraped root applied as a poultice has been found an excellent application to foul ulcers and various cutaneous affections. The bruised leaves are also used for the same purpose. The seeds are diuretic, and employed also by herbalists in nervine elipepsy. The young stalks split open and the rind removed, form a delicate vegetable when boiled. In the raw state they are eaten with oil and vinegar as a salad. Several varieties of this plant are cultivated in Japan as a vegetable under the name of "Gobo." There is an article on its used as a culinary vegetable in the *Journal of the Acclimatisation Society of France*, for August, 1883.

Symphytum officinale.—Comfrey, fr. Latin "confirma;" called also "knit back" from its strengthening and restorative qualities, formerly known as "Consolida major." In the French Codex still called "Grande consoude." Called "bone-set," because the root was used in the form of a poultice and bandage round broken legs, and, in drying, hardened like plaster of paris, forming a splint. The root contains much starch and mucilage, with slight astringency. Principally used internally for what are popularly know as inward wounds, its mucilaginous properties probably being the principal reason of its employment. Boiled in milk used for spitting of blood in consumption. The most marvellous virtue attributed to it by the old writers is, that if it be boiled in a pot with meat that is chopped in pieces, its healing powers are so great it joins the pieces of flesh together again. The young leaves and shoots are sometimes eaten as a vegetable, and are said to form a good and nutritious food. Leaves used to flavour cakes. Comfrey is much relished by cattle, and is frequently cultivated as a fodder.

Marrubium vulgare, white horehound.—Name supposed to be derived from Hebrew "marrob," which signifies a bitter juice. In Arabic languages at the present day "Marout" means a bitter plant. The whole plant has a peculiar aromatic odour, somewhat vinous or musky. Taste, very bitter and astringent. Official in the U.S. Pharmacopœia and French Codex. Not used professionally in this country, although it seems to merit some attention. One of the most popular remedies for coughs, either preserved as syrup or candy, or as an infusion of the dried herb. A decoction of horehound with cayenne pepper is given for colds. It has been found of great service in asthma, chronic catarrh, and pulmonary consumption; it has also been used in scarlatina and intermittent fevers, and as a stimulant and tonic in chlorosis and hysteria. By the ancients it was extensively used with the view of removing obstructions of the lungs and viscera. The green leaves, bruised and boiled in lard, used as an ointment, were reputed to heal dog bites. Linnæus records an instance in which salivation, occasioned by the continued use of mercurial medicines, was removed by the administration of an infusion of horehound, after every other remedy had failed. In Devonshire a beer made with yeast, white horehound, and sugar, is much esteemed as a remedy for coughs, and a palliative in consumption.

Teucrium Scorodonia, wood sage.—Properly wood-germander, called wood sage from the shape of its leaves. The whole plant is very bitter and aromatic, contains volatile oil, and a bitter principle found in all the species of this genus. Much used by herbalists as a tonic for purifying the blood and in chest complaints. With regard to its recent employment, I have been informed on the most trustworthy authority of a difficult case of pyrosis, which was cured by this plant alone. It is used as a poultice with linseed in sores and inflammations. I quote the following from the book of a well-known medico-botanist, Dr. Coffin:—"A patient had a tumour on his left hand the size of a hen's egg. The doctors said he must have it cut or he would lose his hand. Being in great pain he applied a poultice of Indian meal, and wood sage in the green state; he obtained ease in ten minutes. By continuing the same treatment the tumour disappeared in a fortnight."

Verbena officinalis, common vervain.—This plant has been known and celebrated from the most ancient times. Magical virtues especially having been attributed to it in all ages. The Greeks called it ἱερά βοτάνη or holy herb. Virgil says the priests bound it about their temples on the morning of the death of Æneas. In the time of the Druids it was held in high repute, their veneration for it was almost as great as for the mistletoe; they wore it as a charm against evil and witchcraft, and for good luck. In more recent times it entered into the composition of various love-potions, and other mystic compounds. During the last century it was brought forward by an empiric as a remedy for scrofula, a piece of the root being suspended round the patient, while other medicines were taken internally. Its influence in this disease was supposed to be due to sympathetic action. The plant is very bitter, but, notwithstanding all that has been said in its praise, and the marvellous cures it is reputed to have wrought, its medicinal qualities do not appear to be very valuable. The herbalists, even of the present day, consider it of great value. They say that as an emetic it is superior to ipecacuanha, and rank it next to lobelia, which they esteem the best of all; they also say it is one of the most powerful sudorifics in nature. They use it as an antiscorbutic and vermifuge, for colds, coughs, pains in the head, fever, and small-pox. It is still official in France.

Erythræa Centaurium, centaury.—Well known to the ancients; named from Chiron the Centaur, because it cured him of a wound caused by an arrow poisoned with the blood of the Hydra, which he dropped on his foot whilst examining the weapons of Hercules. The plant is nearly inodorous. The taste is intensely bitter, which caused it to be formerly called fel terræ or gall of the earth. It is one of the most valuable of our native plants, and, till lately, was official in our pharmacopœias; it is still included in the French Codex. It is much employed by physicians on the continent in dyspepsia and intermittent fevers, and sometimes as a vermifuge. The principal constituent is "centaurin," a bitter resinous body, which, combined with hydrochloric acid, has proved a powerful and valuable remedy in low fevers. Centaury is a safe and valuable tonic, possessing all the active properties of *Gentiana lutea*; in fact, it is better in some respects, being less apt to disorder the digestive organs than preparations of the latter plant. In intermittent and other febrile disorders it has supplied the place of cinchona bark. It is a general corrective in bile and liver complaints, jaundice, and indigestion. It has been also used in hydrophobia, kidney diseases, and gout. It was a principal ingredient in the once celebrated Duke of Portland's gout powder.

Menyanthes trifoliata, buck-bean, marsh trefoil.—Nearly allied to centaury. It was also official until recently, and is still retained in the French Codex. It possesses somewhat similar tonic properties, is also slightly astringent, and, in large doses, purgative and emetic; its properties are due to an active principle, menyanthin. It has frequently been used as a substitute for bark, as it grows in marshy districts where remittent and low fevers abound. The dried leaves are given, in powder, in doses of 20 to 30 grains in intermittent fevers, chronic rheumatism, and in some cutaneous disorders. The plant is employed medicinally in Germany to a very great extent. In Lapland, in times of scarcity, the dried roots, powdered and mixed with a little flour, are used as food, but the bread thus made is designated by Linnæus as very bitter and detestable. The dried leaves have been used instead of hops for preserving beer, two ounces of dried leaves being equivalent to a pound of hops. The herbalists of the present day extol it as a most valuable bitter, and remedy in biliary complaints. Its virtues, in a book written by one of their number, are said to be far superior to the quinine and morphia of the doctors' shops.

RECENT STUDIES ON THE CONSTITUTION OF THE ALKALOIDS.*

BY SAMUEL P. SADTLER, PH.D,

The sciences of to-day present, as might be expected, a very different aspect from the same branches of knowledge as they appeared fifty or sixty years ago. It is not merely that the mass of observations in most of these lines of study has enormously increased during this interval. Were that all, the change could hardly be considered as an unmixed benefit, because of the increased difficulty of assimilation of this additional matter. Many would be the contradictions in the observations and hopeless would be the task of bringing order out of such a chaos. The advance in the several branches of knowledge has been largely one resulting from improved methods of study, rather than one following simply from diligence in the application of the old ways.

Let us turn to chemistry for our illustration of this. The chemistry of the last century and the early decades of this was largely a descriptive science, such as the natural history branches, zoology and botany, are still in great part. Reasonably exact mineral analyses were made, it is true, but the laws of chemical combination and the fundamental conceptions of atoms and molecules had not been as yet generally established. Now, this want of comprehensive views of chemical reactions, their why and wherefore, was bad enough as it affected the study of inorganic and metallic compounds, but what must have been the conditions for studying the complex compounds of carbon, so widely spread in the vegetable and animal kingdoms. Their number is so enormous that, in the absence of any established relationships, not much more than a mere enumeration was possible for the student of this branch of chemistry. It is only within the last twenty years that chemists have attained to any comprehensive views at all in the domain of organic chemistry. It has been found possible to gradually

* Introductory Lecture, Course of 1883-84, Philadelphia College of Pharmacy. Reprinted from the *American Journal of Pharmacy*.

range most carbon compounds under two categories, either as marsh-gas or as benzol derivatives, as fatty compounds or as aromatic compounds. To do this, methods of analysis very different from those used in mineral chemistry had to be applied. The mere finding out of percentage composition tells us little or nothing about an organic compound. What the elements are that compose the compound is not to be found out. That can be told beforehand with almost absolute certainty. What is wanted is to know how the atoms of carbon, hydrogen, oxygen and nitrogen are linked together, for, strange to say, these differences of groupings, which may be found to exist between these three or four elements, endow the compounds with radically different properties and serve us as a basis of classification.

The development of this part of chemistry, therefore, required very different methods of research. Instead of at once destroying a compound in order to learn of what elements it was composed, we submit it to a course of treatment with reagents, which take it apart very gradually, or modify it in the production of some related substance. In this way, we are enabled to establish its relations with well-defined classes and to put it in its proper place. Of equal importance with the analytical method of study, however, is the synthetical. This method of research, as applied to organic compounds, embodies in it the highest triumphs of modern chemistry. It has been most fruitful of results, both theoretical and practical. Within recent years, hundreds of the products of vegetable and animal life have been built up from simpler compounds. Thousands of valuable dye-colours and other compounds used in the arts attest its practical value. It may, therefore, seem anomalous when I say that one of the most important of all the classes of organic compounds has not shared in this advance. The alkaloids, that most important class from a medical and pharmaceutical point of view, have until quite recently been defined in the books simply as "vegetable bases, containing nitrogen." Whether they were marsh-gas or benzol derivatives was not made out; how the four elements, carbon, hydrogen, oxygen and nitrogen, were grouped together in them was absolutely a thing unknown. Chemists all admitted two things—first, that their constitution was very complex, and, second, that the synthesis of any of the more important medicinal alkaloids would be an eminently desirable thing to effect from every point of view. Within the last five years, however, quite considerable progress has been made in arriving at a clearer understanding of these most important compounds, and I shall offer to your attention this evening a brief statement of what has been done and what seems likely to be accomplished in the near future.

It was early recognized that the alkaloids were complex amines or ammonia derivatives. The more or less strongly marked basic character of these bodies, the presence of nitrogen as an essential element, and, above all, the analogy shown to ammonia in the way these bases united with acids to form salts, not by replacement of the hydrogen of the acid, but by direct addition of acid and base, pointed unmistakably to this constitution. But with this granted, the simplest alkaloid formulas, those of conine, $C_8H_{17}N$, and nicotine, $C_{10}H_{14}N_2$, still showed that the amine molecule contained quite complex groups of carbon and hydrogen atoms, and the great majority of the alkaloids—the non-volatile ones—contained groups in which the three elements, carbon, hydrogen and oxygen, all entered. Hence the difficulty in acquiring a knowledge of the molecular structure of those alkaloids at all comparable with that attained in the case of other organic compounds. Of course synthesis could not be applied until analysis had revealed something of the molecular grouping of these compounds, so the action of different classes of reagents was tried upon the alkaloids. Before summarizing the results of this study of the decomposition and alteration products of the alkaloids, a brief reference to a related class of organic compounds will be of assistance to those unfamiliar with recent researches in this field.

It is well known that in coal-tar is found a series of ammonia-like bases, aniline or amido-benzol, toluidine or amido-toluol and xylidine or amido-xylol, which are utilized practically in the manufacture of the so-called aniline dye-colours. It is perhaps not so well known that there are other series of bases found there too. The first of these is the pyridine series, including *pyridine*, C_5H_5N, *picoline* (methyl-pyridine), $C_5H_4N\ (CH_3)$, *lutidine* (dimethyl-pyridine), $C_5H_3N\ (CH_3)_2$ and *collidine* (trimethyl-pyridine), $C_5H_2N\ (CH_3)_3$. This series is also found in relatively larger proportion in what is known as Dippel's oil, the product of the dry distillation of bones.

The second series is the quinoline series, including *quinoline*, C_9H_7N, *lepidine* (methyl-quinoline), $C_{10}H_9N$, and *cryptidine* (dimethyl-quinoline), $C_{11}H_{11}N$. The two compounds which give name to these series, pyridine, C_5H_5N, and quinoline, C_9H_7N, respectively, bear to each other a relation analogous to that existing between benzol, C_6H_6, and naphthalene, $C_{10}H_8$, and the theory generally accepted by those chemists who have been occupying themselves with these bases and their derivatives is that pyridine is simply benzol, in which an atom of nitrogen replaces the triad group, CH, and quinoline, the naphthalene molecule with a similar change. Indeed, Ladenburg has recently succeeded in obtaining benzol as an alteration product from pyridine in certain reactions. Moreover, from methyl-pyridine, $C_5H_4N\ (CH_3)$, would be derived an acid known as pyridine-carboxylic acid, $C_5H_4N\ (COOH)$, just as benzoic acid, C_6H_5COOH, is derived from methyl-benzol, $C_6H_5CH_3$, and from dimethyl-pyridine, $C_5H_3N\ (CH_3)_2$, an acid known as pyridine-dicarboxylic acid, $C_5H_3N\ (COOH)_2$, just as phthalic acid, $C_6H_4\ (COOH)_2$, is derived from dimethyl-benzol, $C_6H_4\ (CH_3)_2$. The same thing applies to quinoline as compared to naphthalene.

We may now look at the question of the decomposing effect of reagents upon the alkaloids. The means which have proved most efficacious in decomposing these bases are the action of oxidizing and reducing agents, of bromine, of organic iodides, of concentrated acids and alkalies, and of heat.

Taking up the volatile alkaloids, we find with regard to *Conine*; first, that the action of methyl iodide shows it to be a secondary amine, that is, it retains only one replaceable hydrogen atom of the original ammonia molecule. Its formula is therefore $C_8H_{16}NH$. From conine can be prepared methyl-conine, which also occurs in nature, and dimethyl-conine. From this latter has been gotten a hydrocarbon, C_8H_{14}, conylene, homologous with acetylene, C_2H_2. Conine, on oxidation, yields chiefly butyric acid, but among the products of oxidation has been found the pyridine-carboxylic acid before referred to. The formula of conine, $C_8H_{17}N$, shows it to be homologous with piperidine, $C_5H_{11}N$, a derivative of piperine, the alkaloid of pepper, to be spoken of later, and, just as piperidine is derived from pyridine by the action of reducing agents, so conine is probably derived from a propyl-pyridine. The artificial alkaloid, paraconine, isomeric with the natural conine, will be referred to later.

Nicotine, $C_{10}H_{14}N_2$, the next simplest in formula of the alkaloids, is a tertiary base, that is, contains no replaceable hydrogen atoms in its molecule. It shows very close relations to pyridine. When nicotine vapour is passed through a red-hot tube, it yields essentially collidine, and with this some pyridine, picoline, lutidine and gases such as hydrogen, marsh gas and ethylene. Heated with bromine water to 120° C., it decomposes into bromoform, carbon dioxide, nitrogen and pyridine. When its alcoholic solution is treated with ferricyanide of potassium it is oxidized to dipyridine, $C_{10}H_{10}N_2$. Potassium permanganate, chromic or nitric acid oxidizes it to nicotinic acid, $C_6H_5NO_2$, which is simply pyridine-carboxylic acid, C_5H_4N (COOH), and which, distilled over quicklime, yields pyridine, C_5H_5N.

Turning now to the non-volatile and oxygenized bases, we take up first the opium alkaloids. *Morphine*, $C_{17}H_{19}NO_3$, is a tertiary amine, and appears to contain a hydroxyl group like phenols, to which class of bodies it has some analogies, as is shown in its reaction with ferric chloride. Its methyl ester, which can be formed from it, is *Codeine*, one of the accompanying alkaloids of opium. Besides the methyl derivative, however, others are possible, and several have been recently prepared, giving rise to a class of artificial alkaloids known as *codeines*. Morphine, rapidly distilled over zinc dust, yields phenanthren, trimethyl-amine, pyrrol, pyridine, quinoline, and other bases. The action of strong hydrochloric acid upon morphine changes it into apomorphine, $C_{17}H_{17}NO_2$, by the withdrawal of a molecule of water. Ferricyanide of potassium and caustic soda solution change morphine into oxydimorphine, $C_{34}H_{36}N_2O_6$. When heated with strong potassium hydrate, it yields methylamine.

Narcotine, another of the opium alkaloids, when heated with manganese dioxide and sulphuric acid, is oxidized and splits apart into opianic acid, $C_{10}H_{10}O_5$, and cotarnine, $C_{12}H_{13}NO_3$. This latter, by careful oxidation, yields apophyllenic acid, $C_8H_7NO_4$, and this, on heating with hydrochloric acid to 240° C., yields pyridine-dicarboxylic acid, $C_5H_3N(COOH)_2$. The base cotarnine also results from the prolonged heating of narcotine with water alone. In this case, instead of opianic acid, its reduction product meconine, $C_{10}H_{10}O_4$, is produced.

Meconic acid, $C_7H_4O_7$, which is found in opium in combination with the different bases, has also been investigated. By acting upon meconic acid with ammonia, comenamic acid is formed, and this latter, when heated with zinc dust, yields pyridine.

If we go now to the cinchona alkaloids, we meet with exceedingly interesting results. *Quinine*, $C_{20}H_{24}N_2O_2$, when carefully oxidized with chromic acid or potassium permanganate, yields a series of products. First is formed quitenine, $C_{19}H_{22}N_2O_4$, a weak base, then quininic acid, $C_{11}H_9NO_3$, then the so-called oxycinchomeronic acid, $C_8H_5NO_6$, and finally cinchomeronic acid, $C_7H_5NO_4$. Now the two acids last mentioned are simple substitution products of pyridine, oxycinchomeronic acid being a pyridine-tricarboxylic acid, $C_5H_2N(COOH)_3$, and cinchomeronic acid, a pyridine-dicarboxylic acid, $C_5H_3N(COOH)_2$. When distilled with potassium hydrate, quinine yields quinoline and its homologues. The alkaloid has been shown to be a tertiary base.

Quinidine yields with chromic acid the same decomposition products as quinine.

Cinchonine, $C_{19}H_{22}N_2O$, the second most important alkaloid of these barks, when oxidized with potassium permanganate, yields cinchonic acid, which is a quinoline-carboxylic acid, $C_9H_6N(COOH)$, cinchomeronic acid, which has just been stated to be a pyridine-dicarboxylic acid, and a pyridine-tricarboxylic acid. When cinchonine is treated with potassium hydrate, it is decomposed into quinoline and a solid body, which on further treatment yields a liquid base C_7H_9N, which is probably lutidine. It has been found, moreover, that both tetrahydroquinoline and dihydroquinoline, hydrogen addition products of quinoline, are present. When cinchonine is distilled with solid potassium hydrate, it yields pyrrol and bases of both the pyridine and quinoline series.

Cinchonidine, when heated with potassium hydrate, yields quinoline also, and with nitric acid the same products as cinchonine.

Strychnine has been found to be a tertiary amine. When distilled with potassium hydrate, quinoline is formed.

Brucine is a tertiary diamine, that is, formed by substitution in a double ammonia molecule. When distilled with potassium hydrate it yields quinoline, lutidine, and two isomeric collidines.

The alkaloid *Atropine* has been quite thoroughly studied with results of great interest. When heated with either baryta-water or hydrochloric acid, it takes up a molecule of water and is split into tropine, $C_8H_{15}NO$, and tropic acid, $C_9H_{10}O_3$. This latter is phenyl-oxypropionic acid. Tropine, when heated to 180° C., with concentrated hydrochloric acid, splits off a molecule of water, and yields tropidine, $C_8H_{13}N$, a liquid base, with an odour resembling conine. When this tropidine is heated with an excess of bromine, it yields dibrompyridine.

Piperine, the alkaloid of pepper, has also been well-studied. When boiled with alcoholic potash solution, it takes up a molecule of water and splits apart into piperic acid, $C_{12}H_{10}O_4$, and piperidine, $C_5H_{11}N$. This latter base has been shown to be a hydrogen addition product of pyridine, C_5H_5N. When heated with concentrated sulphuric acid, it is oxidized to pyridine. Piperidine hydrochlorate, also, when heated with excess of bromine to 180° C., yields dibrompyridine.

Sinapine, the alkaloid which exists as sulphocyanate in white mustard seed, yields under the same reaction as that applied to atropine and piperine, quite different results. When boiled with baryta water, sinapine decomposes into sinapic acid, $C_{11}H_{12}O_5$, and choline, $C_5H_{15}NO_2$, the latter a well-known constituent of the bile, and produced also in the decomposition of the lecithin of the brain and yolk of egg.

Cocaine, the alkaloid of coca leaves, is decomposed by heating with hydrochloric acid into methyl alcohol, benzoic acid and a crystalline base ecgonine, $C_9H_{15}NO_3$.

Caffeine and *theobromine* have also quite different relations. Caffeine, it will be remembered, is the methyl ester of theobromine, and can be prepared from it. When caffeine is carefully oxidized with chlorine, it yields dimethyl-alloxan and methyl-urea. Both theobromine and caffeine are decomposed by heating to 240° C. in sealed tubes with hydrochloric acid, identical products being obtained. These products are carbon dioxide, formic acid, ammonia, methylamine, and sarcosine, the last three being of course in combination with the excess of hydrochloric acid. The artificial preparation of theobromine and caffeine from xanthine and guanine also shows clearly their relations.

If, having completed our survey of what has been done in the way of decomposing the alkaloids by the different classes of reagents, we review the field, it will be seen that with all the alkaloids mentioned, except the last four, a more or less immediate connection with the pyridine and quinoline bases has been indicated. The conviction accordingly forces itself upon us that, if we want to attack the problem of building up any of these important alkaloids artificially, we must turn to these bases as our starting point.

As already stated, both series occur in coal-tar and the pyridine series also more abundantly in bone-oil. Pyridine, picoline, lutidine, and collidine, the first four members of the pyridine series, have, moreover, all been formed synthetically, although the processes are not such as would yield the products as cheaply as they can be gotten from Dippel's oil. Quinoline, the first member of the higher series, had been made synthetically by several chemists, but by expensive and involved methods, when Skraup, in 1881, effected its synthesis from nitrobenzol and glycerin, or still better, a mixture of nitrobenzol and aniline with glycerin. This process allows of its being made on a commercial scale if desirable. Shortly after, by an application of the same principle, Döbner and Miller effected the synthesis of lepidine, the second member of the quinoline series.

At the same time that this general agreement to consider these bases as the starting point in the endeavour to effect the synthesis of the natural alkaloids had been arrived at by chemists, it was thought well to look into the question whether these bases and their immediate derivatives had any therapeutic value of their own.

Piperidine, the decomposition product of piperine, which we have shown may be considered to be hexahydropyridine, was examined by Dr. Kronecker, of Berlin, at the request of Professor Hofmann, and was found to have an action upon animals in many respects resembling that of conine. Professor Filehne, of Erlangen, who has studied a large number of these pyridine and quinoline derivatives, found, moreover, that the hydrochlorate of ethyl-piperidine had a physiological action quite analogous to that of conine.

The physiological action of quinoline itself has been studied quite extensively by Donath and others, and it was found that several of its salts were quite valuable febrifuges, acting very like quinine, and capable in cases of being used as a substitute for it. In general, the hydrogen addition products were found to be more active than the simple base, an observation entirely in accord with the theory formed by Wischnegradsky, and by Königs, as the result of the study of the decomposition products of the alkaloids, viz., the alkaloids are in general hydrogen addition products of pyridine and quinoline, or of the two bases combined. Thus, Professor Filehne found that hydrochlorate of tetrahydroquinoline was much more energetic in its action than quinoline, but could not be used on account of a too powerful local effect. The hydrochlorate of dimethyl-tetrahydroquinoline, which was distinguished by its strong bitter taste, much resembling that of quinine, had an effect like that of curare poison. The most decided febrifuge action, however, was found by Professor Filehne to reside in the hydrochlorate of oxyhydro-methyl-quinoline, introduced to public notice by Professor O. Fischer under the name of "kairin," and in the acid sulphate of tetrahydro-methylquinoline, introduced under the name of "kairolin." These compounds had a very surprising febrifuge action, without any unpleasant after-effects or local disturbances.

The most active workers in the field of synthetic formation of the alkaloids have been Wischnegradsky, of St. Petersburg,—who, unfortunately for science, died at an untimely age in 1880,—Königs and Fischer, of Munich, and Ladenburg, of Kiel. The study of the decomposition products of the cinchona alkaloids especially points quite distinctly to the probable existence in quinine of a hydrogen addition product of pyridine, in combination with a methyl-quinoline group. The many experiments that are now being made to test this and other questions that suggest themselves will not long leave us in the dark. Whether a practical commercial synthesis of quinine will follow is another matter, but it is within the bounds of possibility, or perhaps even of probability.

It must not be supposed that no syntheses of alkaloids have been effected as yet. By heating butyl-aldehyde with alcoholic ammonia is formed *paraconine*, an alkaloid isomeric with the natural conine, but differing in physiological action. By the action of sodium upon pyridine is produced a compound, $C_{10}H_8N_2$, known as dipyridyl, and this, under the influence of nascent hydrogen, takes up six atoms and becomes *isonicotine*, $C_{10}H_{14}N_2$, a physiologically active alkaloid, isomeric with the true nicotine. The formation of a series of alkaloids under the name of *codeines*, by the substitution of other organic radicals instead of methyl in the codeine reaction, has already been alluded to. *Atropine* can be formed by uniting tropine and tropic acid, the two decomposition products already noted. The latter of these products is already shown to be capable of synthetical formation, and the other will no doubt be formed in the same way. The artificial atropine is identical with the natural alkaloid. Ladenburg has also formed a series of artificial alkaloids, called *tropeines*, by uniting the base tropine with different organic acids, as in the case of the compound of mandelic acid and tropine known as *homatropine*, an alkaloid of action similar to atropine, but possessing some decided advantages in its use. *Piperine* has also been made by the uniting of piperidine and piperic acid, and, as piperidine has already been formed from pyridine, we have here a true synthesis also. Both *theobromine* and *caffeine*, its methyl derivative, have been made from xanthine, which itself can be formed from guanine, a constituent of guano.

We may conclude, from this reference to what has been done in the last few years, that the reproach mentioned in first speaking of the alkaloids as a class, that almost nothing was known of their constitution, will not long remain, and that as their molecular structure is laid bare in these studies now being made, keen-sighted chemists will effect their artificial formation. When these most valuable compounds can be made by exact methods, in a state of entire purity, and at a cost much below that paid for the present extraction of them from relatively rare plants, organic chemistry will have placed all of us under obligations as great as those owing any branch of science, no matter how practical we call it.

SAPONIN.*

BY E. STÜTZ.

At the commencement of this paper, an historical account is given of saponin, a compound obtained from the *Saponaria rubra* and its allied species. The formulæ proposed for this substance, deduced from the percentage proportions of carbon and hydrogen found in it, are various, but most experimenters are agreed in proving that it is decomposed on boiling with acids, yielding a carbohydrate among other products.

The source of the saponin studied in this paper was the bark of the *Quillaia saponaria*, a member of the Spiræa family, indigenous in Chili and Peru. This was digested with water, the extract evaporated down, and hot alcohol of 90 per cent. added; on cooling, white flocks of saponin separated, which were then frequently recrystallized from alcohol, and finally purified by animal charcoal.

Saponin thus obtained is a white, amorphous, neutral powder, generally possessing an astringent taste, due to traces of impurities; it is soluble in water, insoluble in absolute alcohol and ether; its aqueous solution forms a lather like soap. When heated to 195° it turns brown, and at a higher temperature evolves a vapour resembling caramel in odour.

The author was unable to obtain saponin free from inorganic impurities; and from the properties of its barium compound it would appear probable that the impurities, principally consisting of calcium, were intimately associated with the saponin. From the mean of four concordant analyses the formula $C_{19}H_{30}O_{10}$ is deduced.

A concentrated aqueous solution of saponin is precipitated by baryta-water; a substance of composition

$$2C_{19}H_{30}O_{10} + Ba(OH)_2$$

being formed, from which the barium is not readily separated by carbonic anhydride. In order to determine the number of alcoholic hydroxyl-groupings present in saponin, it was heated with acetic or butyric anhydride under various conditions. A series of acetyl-derivatives was thus obtained; amongst which are enumerated a tetracetyl, $C_{19}H_{26}\overline{Ac}_4O_{10}$, and a pentacetyl, $C_{19}H_{25}\overline{Ac}_5O_{10}$, derivative, and two compounds formed by the addition of acetic anhydride to the latter substance, viz., $C_{19}H_{25}\overline{Ac}_5.O_9(O\overline{Ac})_2$, and $C_{19}H_{25}\overline{Ac}_5O_8(O\overline{Ac})_4$ From these results it follows that the saponin contains five hydroxyl groups and two oxygen atoms combined only with carbon; its constitutional formula will thus be: $C_{19}H_{25}(OH)_5.O_2.O_3$. From the acetyl-derivatives saponin can be regenerated.

The Pharmaceutical Journal.

SATURDAY, APRIL 19, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

JEAN BAPTISTE ANDRÉ DUMAS.

SIXTEEN months have barely passed since the occasion of a rare compliment paid by the Academy of Sciences to the greatest of contemporary French chemists, in a jubilee celebration, furnished us with an opportunity for referring to some events in the earlier parts of his career, when it was still associated with the routine of a French pharmacy, and now we have to record the fact that DUMAS is dead. France has lost a son who has richly helped to maintain her claim to pre-eminence in the realms of science, and every other civilized country will join her in paying a grateful tribute to the memory of the philosopher who passed away at Cannes on Friday last. But in the presence of so full a life of eighty-four years it would seem idle to affect surprise that the close should come, and almost irreverent to express much sorrow. Long as was this term of years they were crowded by DUMAS with effective work, and the results form no mean part of our present knowledge of physiology, and especially of chemistry. In any case the interest which the readers of this Journal would have in one who has contributed so much towards building up on a solid foundation the science which exercises a most important influence in their daily avocations would have been great, but in respect to DUMAS this is enhanced by the fact that it was in a pharmaceutical laboratory DUMAS made his first chemical experiments and that nearly half a century afterwards he was chosen to preside over a commission entrusted with the revision of the Pharmacopœia of his native country. It may be that these points of contact with pharmacy had their influence in inducing the Pharmaceutical Society of Great Britain to reflect honour upon itself by, in 1870, placing the name of the illustrious chemist upon its roll of honorary members; certainly they will be our sufficient warrant for referring again to some phases of his life and especially, but only briefly, to work not mentioned in our previous notice.

JEAN BAPTISTE ANDRÉ DUMAS was born in the closing year of the last century at Alais, in the department of the Gard. Originally intended for the naval profession, his aspirations in that direction were diverted by the political events of 1814–15, and he became an apprentice to a pharmacist in his native town. His opportunities there, however, appear not to have been commensurate with his ambition, and in 1816 he went on foot to Geneva, where, in addition to attending the lectures of DE CANDOLLE, PICTET and DE LA RIVE, he acquired practical experience as superintendent of a pharmaceutical laboratory. It was in this room that he delivered his first lectures on chemistry to a knot of fellow students, and it was there that in the ordinary course of business he made an analysis of sponge, which led to the introduction of iodine compounds into the materia medica. Before he was eighteen years of age he had produced two memoirs, one recording the observation that the water of crystallization is present in salts in definite equivalents, in which, however, he had been anticipated by BERZELIUS; the other laying down principles that still rule in the method of taking the density of solid bodies, and on which all subsequent inquiries on the atomic and equivalent volumes of bodies have been based. Whilst still occupied in the pharmacy a futile attempt to isolate the active principle of digitalis brought him into communication with PRÉVOST, with whom he soon became associated in systematic physiological investigations that have left their names indelibly connected with the study of the nature of blood and of fecundation. Indeed, it was the success of DUMAS as a physiologist that eventually brought him back to his chemical labours; for it led to a visit from HUMBOLDT, whose conversation raised in him an insatiable desire to visit Paris, which was gratified in 1823. There, through the influence of ARAGO, he obtained the post of assistant to THENARD at the École Polytechnique, whilst soon afterwards AMPÈRE obtained for him the chair of chemistry at the Athenæum, just vacated by ROBIQUET, and thus DUMAS came again fully under the influence of his earlier mistress, Chemistry. Notwithstanding the time taken up by these official duties, and the paucity of suitable apparatus, DUMAS at once re-entered the field of experimental investigation, and in 1826 published his classic memoir "On Some Points of the Atomic Theory," in which he stated that he was engaged in experiments intended to fix the atomic weights of a considerable number of bodies "by determining their density in the state of gas or vapour," and shadowed forth the distinction between molecules and atoms by urging the necessity of giving greater attention to AVOGADRO'S hypothesis that the molecules of gases were capable of further division, the division occurring in the moment of combination. About this time, too, he resumed with BOULLAY a dropped investigation of the compound ethers, which eventually not only threw a flood of light upon the relations that exist between what is now distinguished as ethylic alcohol and its ethers, but led to the discovery that in wood spirit, spermaceti, and potato spirit there were other bodies, exhibiting similar properties, each producing with acids its series of ethers and yielding an acid when treated with oxidizing agents, whilst they differed from one another in composition by one equivalent of carbon and two of hydrogen, or multiples of that quantity. Here was the first page in the history of the homologous alcohols and their derivatives, which has since become one of the most richly developed in the domain of chemistry. Whilst following up this investigation an apparently fortuitous inconvenience suffered at a *soirée* at the Tuileries through the irritating vapours diffused from some wax candles led to the inference that chlorine used in bleaching had been retained by the wax in definite proportions, the outcome being the theory of substitution, which opened up a new world of research to chemists. In 1846 DUMAS showed that between formic and margaric acids it was possible that there existed a series of fifteen other acids, of which only nine were then known, passing from one extreme to the other by steps of CH_2, and thus was provided the starting point for the homologous classification of the fat acids. Between 1858 and 1860 DUMAS published the results of numerous researches in previous years upon atomic weights of the elements, which, like the manipulative processes associated with his name, had been incidental but necessary preliminaries to the satisfactory performance of other work. Thus the correction of the atomic weight of carbon, which had been fixed by BERZELIUS at 12·24, was indispensable to any satisfactory progress in knowledge of the carbon compounds. It was natural that under these circumstances he should have devoted much attention to the examination of PROUT'S hypothesis that the different elements consist of the same primordial matter in different physical conditions, and although his results precluded an admission that the theory was supported by the atomic weights of all other elements proving to be multiples of hydrogen taken as unity, he seems not to have been disinclined to believe that the unity would be found at some lower point. At any rate, his speculations in connection with this question were very ingenious and interesting and went much further than is generally admitted towards the establishment of what is now known as the "periodic law." Afterwards his experimental work again approached the field of physiology, in that it was devoted to the phenomena of nutrition, the formation of sugar in the organism, the composition of blood, and allied questions, and in 1872 he published his theory as to the nature of alcoholic fermentation.

Notwithstanding the variety and scope of the investigations thus hinted at rather than outlined they formed only a part of the labours of DUMAS. To these must be added his work as professor, author, journalist, member of numerous commissions, politician and Perpetual Secretary to the Academy of Sciences. These all belong to his public services, which is the portion of his life in which we are most interested. But there is another aspect of the man that should not go unnoticed. It would seem as if he regarded the valuable sympathy and help given to him liberally in his earlier years by HUMBOLDT, LAPLACE, ARAGO, and other eminent men, as a trust to be handed on to succeeding aspirants to fame. His relations with his contemporaries were also admirable, and although he engaged in some sharp polemical passages with men working on similar subjects, they were never allowed to become embittered or lead to injustice. Thus, although BERZELIUS, naturally disturbed by the irreverent manner in which some of his conclusions as to the atomicity of the elements were overthrown by the experimental work of the younger man, did not hesitate to adopt a tone which was apt to provoke retort, DUMAS went out of his way years after, when again writing on the subject, to caution experimenters that if working under the same conditions they arrived at results different from those put on record by BERZELIUS, it would be the safer plan for them to assume that they had made a mistake. So also with LIEBIG: the many collisions between the two great chemists did not prevent DUMAS from publicly testifying to the admiration he felt for his great German rival, or LIEBIG from dedicating to DUMAS an edition of his famous 'Familiar Letters.' DUMAS was equally generous in his recognition of the genius of our own countryman, FARADAY, and a passage taken from the first Faraday Lecture, delivered by him in 1869, may with a slight alteration be well addressed to France at the present time—

"Mutato nomine, de te
Fabula narratur."

"The name of your illustrious fellow-countryman "is not one which any single nation can claim as its "exclusive property; his labours and discoveries are "as widely recognized in England, in Germany, and "in America, as in France. DUMAS belongs to the "whole world. There is not a spot on this earth to "which civilization has penetrated that does not "claim the right of participating in the respect and "gratitude you entertain for him."

The Aberdeen Society of Chemists and Druggists met in the Palace Hotel, on April 8, to present their esteemed Secretary, Mr. Alexander Strachan, with a testimony of their appreciation of his services in connection with the Society. The testimonial took the form of a marble timepiece, two equestrian bronzes, and a complete set of table cutlery. The meeting was largely attended and enthusiastic.

* * *

The Secretary of State for India has been pleased to appoint Mr. David Hooper, F.C.S., as Quinologist to the Nilgiri Government Cinchona Plantations in the Madras Presidency. Mr. Hooper was a Pereira Medallist of the Pharmaceutical Society in 1880, and has been lately engaged as analyst in the laboratory of Messrs. Southall, Brothers and Barclay.

In connection with the forthcoming International Health Exhibition provision is being made for an ample supply of literature in the form of a series of official Hand-books. Among these are to be specially written works on 'Healthy and Unhealthy Houses in Town and Country,' by Mr. W. Eassie and Mr. Rogers Field, C.E.; 'Heating, Lighting, and Ventilation,' by Captain Douglas Galton; 'Food,' by Mr. A. W. Blyth; 'Principles of Cookery,' by Mr. S. Berdmore; 'Food and Cookery for Infants and Invalids,' by Miss Wood; 'Alcoholic Drinks,' by Dr. J. L. W. Thudichum; 'Non-Alcoholic and Aërated Drinks,' by Professor Attfield; 'Fruits of all Countries,' by Mr. W. T. Thiselton Dyer; 'Condiments, including Salt,' by the Rev. J. J. Manley; 'Laboratory Guide to Public Health Investigation,' by Mr. W. W. Cheyne and Dr. W. H. Corfield; 'Physiology of Digestion and the Digestive Organs,' by Professor Arthur Gamgee; 'Fermentation,' by Dr. Duclaux; with a Preface by M. Louis Pasteur; and 'Spread of Infection,' by Mr. Shirley F. Murphy. It is announced that the Exhibition will be opened on Thursday, the 8th of May, by H.R.H. the Duke of Cambridge, acting on behalf of the President, H.R.H. the Prince of Wales.

* * *

The recent convictions in Massachusetts for the sale of drugs not answering to the standard of the United States Pharmacopœia appear to have provoked a curious counter-move. It is reported that an attempt is to be made to deprive the Pharmacopœia of the precedence at present accorded to it as the authoritative standard for the quality of articles included in it and bring it down to the level of a "community," whilst the 'United States Dispensatory,' which is essentially a commentary on the Pharmacopœia, is to be raised to the dignity of chief standard. As, however, there are at least two other important rivals of the 'Dispensatory,' which, like it, are private ventures, it is not probable that the attempt, if made, will succeed without a struggle.

* * *

An extraordinary specimen of paternal legislation has recently been introduced into the United States National House of Representatives, with the view of preserving from temptation the Chinese and other opium consumers in that country. The Bill provides for the prohibition absolutely of any importation of opium except in the form of aqueous extracts for medicinal use and tinctures, and would subject any person contravening its provisions by importing or dealing in solid opium to imprisonment for a term not exceeding five years.

* * *

Many of our readers will see with regret the account on another page of the circumstances attending the death of Dr. Henry Brown, of Northallerton, in whom they will recognize a former frequent correspondent of the "Dispensing Memoranda" columns of this Journal. Although the positive tone in which the communications of Dr. Brown were usually couched had a tendency to provoke irritation, there could be no doubt that the motive which prompted them was a sincere wish to impart useful information, and in discussing the different topics he frequently evinced a knowledge of pharmacy, and an appreciation of its importance, beyond what is usually manifested by medical practitioners.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, April 23, when a paper on "The Alchemists: their Failure and their Success," will be read by Mr. S. R. Atkins.

Transactions of the Pharmaceutical Society.

EXAMINATION IN EDINBURGH.

April 9th and 10th, 1884.

Present on both days—Messrs. Baildon, Clark, Gibson, Gilmour, Kinninmont, Maben, Nesbit and Stephenson.

Professor Maclagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

9*th.—Sixteen* candidates were examined. *Nine* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Aspinall, William..................Platt Bridge.
Barlow, Ernest Silas ....Oldham.
Cappell, Robert ....Crieff.
Christie, James......................Old Meldrum.
Drake, Harry Francis............Stowmarket.
Graham, Thomas Andrew ......Stirling.
Hamilton, Francis ....Glasgow.

10*th.—Fourteen* candidates were examined. *Nine* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

McGuffie, Wm. Alexander ......Stranraer.
McIntyre, James ....Grantown.
Manson, William Mackenzie ...Edinburgh.
Riddiough, Fred ....Leeds.
Robertson, George ....Burntisland.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

A general meeting was held on Friday, March 28, at the Museum and Library, Queen's Road; Mr. James Walter White, President, in the chair.

After expressing in a few earnest sentences his appreciation of the services rendered to the Association by his predecessor, Mr. Schacht, Mr. White addressed the meeting as follows:—

"Gentlemen,—On such occasions as the present it has become the established rule for the President to open the proceedings with a few introductory remarks, sometimes called an address; and at first sight there would seem to be the very widest field for the choice of a subject connected with our calling. For the aspect of pharmacy is very many-sided, and the practice of its art comprises branches of knowledge so varied, and so comprehensive, that no man bound by the limits of average human intelligence can hope to acquire an intimate acquaintance with them all. Accordingly one finds that our trade literature abounds with dissertations upon all the arts and sciences allied to pharmacy; its ethics, and its trade questions, mingled with exhortations to young druggists entering upon life, and lucubrations from old ones about to quit it.

"As is to be expected also all kinds of opinions are represented in these addresses, and their matter has been considered from all points of view. For instance, you will find on the one hand that students are encouraged to consider themselves, one and all, adolescent Faradays and Tyndalls, needing only industry, perseverance and the flux of time, to develop into paragons of science and mines of wealth. On the other hand, you will see displayed to these same students all the perils of ambition; how far preferable it must prove to live content as honest mediocrities, and the supreme folly of attempts to set the Thames on fire.

"Again, to some minds, the business of a chemist and druggist has appeared to be invested with the status of a learned profession; whilst more matter of fact spirits have acknowledged themselves to be mere drudges, whose mission was simply to work hard, live hard, die hard, and—not to expect much increase of dignity afterwards. There is of course nothing very remarkable in these diversities of opinion, and their mode of expression is generally admirable. They are commented on here simply as tending to show how thoroughly threshed out the subjects have been. Would that the process had resulted in a more copious yield of golden grain! and in making that remark I touch upon the dismal topic of the present condition of pharmacy. Perhaps it may be deemed fitting to the occasion if I restrict myself this evening to making in a few plain words a sort of profession of faith in relation to the topic just mentioned, because although my individual views may carry little weight, yet in the circumstances under which we meet, it would seem right to express them to my fellow members.

"Notwithstanding the immense advance in some directions which has been made through the influence of the Pharmaceutical Society, aided by the efforts of kindred associations established for the promotion of scientific pharmacy, it cannot be denied that as a body we have very grave reasons for dissatisfaction with the condition of our trade. I wish to state my belief that although the sources of discouragement are undoubtedly grievous, we are apt to lay too much stress upon some of them, and to show an amount of faintheartedness which does us little credit.

"Formerly the trade of a chemist and druggist was thought to be a very desirable one. The cost of apprenticeship, although higher than in many other trades, was not excessive, and the capital required for commencing business was comparatively small. Further, it was thought to be a genteel trade, requiring a greater amount of school learning than most others, involving the exercise of some scientific knowledge, and partaking in a small degree of the character of a profession. The profits, comparing isolated transactions with those of other trades, appeared to be very great, and indeed the business did offer the means of easily acquiring a moderate income.

"Now this was a condition of things far too good to last. It meant that even an ignoramus could make a decent living as a chemist and druggist, whilst people possessing an average amount or more of scientific knowledge and business aptitude were certain of attaining affluence. Our fathers benefited also from the profuse system of medicine taking which prevailed at the time, and which induced people to think that it was necessary to attack a disease with an array of physic bottles, just as soldiers attack a town with batteries of guns; but that system has had its day, and has produced a revulsion from which we are now suffering to some extent. With the advance of time came other changes more momentous. Increasing populations striving for means of livelihood crowded into the professions and trades and gave rise to unwonted competition. Thus it has come to pass in our day that only the fittest have a prospect of surviving in the throng, and that the blockheads are going to the wall. It is this keen competition which presses us most sorely; but it is inevitable, and must be manfully met and grappled with. For the world moves on, the old gives place to the new, and the imperfect to that which is more perfect; and though this progress often involves hardship to individuals, no sensible person will think it possible to arrest it. For my own part I do not believe any good can result from one-sided denunciations of the evils, real or imaginary, of cutting shops, or of co-operative trading. Both are facts, the existence of which must be recognized, and it is only by rigorous competition that we can hope for a solution of the problem which has now for some time perplexed tradesmen. Protective legislation cannot be hoped for, even if it were worth having; and, although the trial will probably be severe and damaging, the sooner it is faced the better.

"There is but one safe course to pursue. If blockheads and ignorami must henceforth starve, and only the most capable are to thrive, let us, by dint of scientific culture, and activity in business, endeavour to avoid being included in the former category, that we may share the success of the latter.

"A very mortifying phase of this competition trouble is the fact that the public are, with some exceptions, so slow to recognize that the responsibilities, knowledge, and scientific attainments of the latter-day pharmacist are worthy of some professional remuneration. Notwithstanding his life of anxiety, and of unremitting study and toil, he is begrudged any emolument he may claim on account of his responsible duties over and above a bare profit on the goods sold. We may reasonably expect that time will modify this anomaly.

"Another source of discouragement is the difficulty we experience in winning the confidence of the medical profession. A pharmacist may become a repository of all knowledge relating to the natural history, the commerce, the chemistry, the preparations, the properties, the doses, and the modes of administration of everything used in medicine. He may be an accomplished *savant*, and his name may be a household word throughout the world of pharmacy, yet the physicians of his own neighbourhood will scarcely trust him to make two grains of quinine into a pill. Very often they will prefer to have the pill prepared three thousand miles away by persons of whom they can know nothing at all, save that they have imported into this country attractive-looking assortments of such medicines, remarkable solely for the brilliancy of their hue, and the eccentricity of their shape. It might be expected also that the prescriber wishing to try a new remedy, or to administer a medicine in some new form, would look to the pharmacist as an intelligent adviser, with whom he might confer on practical points, which are important in guiding his decision. I am glad to acknowledge that this does often happen; but how often also do we have an experience like the following. A remedy is advertised purporting to be made from a herb gathered somewhere in the Antipodes, a plant without a name even, whose botanical affinities have not yet been ascertained, but whose virtues are extolled on faith of Indian medicine-men. This precious article is prescribed right and left, until presently a fresh nostrum engages attention, and the other falls into oblivion.

"Still another disappointment seems to be in store for the British pharmacist. He has excellent and well-founded claims for a substantial share in constructing our national Pharmacopœia: for taking that part which his fellows fulfil with benefit to the state in every civilized community besides our own. But by the time his claims are admitted, if ever they be, that work will possibly have ceased to exercise any influence on the medical mind, and may have been discarded by the prescribing doctor. *His* pharmacopœia bids fair to be the advertising pages of the medical journals, supplemented by circulars and samples, shoals of which pour in upon him daily. The poor pharmacist may find that he has been chasing an *ignis fatuus*, and once more may have to pocket his dignity with a sigh.

"We must hope, and indeed we cannot doubt that it may be possible, to counteract, and to prevail over these degrading and demoralizing tendencies by a right use of the means at our disposal. I believe that of those means, the highest scientific education applied in a sound commercial spirit will be found the most effectual.

"Let us trust that although our own personal aspirations may have been quenched in disappointment; it may yet remain for our posterity in the near future to enjoy that status and those rewards which we have striven to deserve."

Mr. G. F. Schacht then offered a communication upon—

Extract of Nux Vomica, and some Methods of Estimating the Alkaloids it contains.

Mr. Schacht said that his first words should be to remind his audience that the chief part of what he should endeavour to put before them was the result of the labours of two gentlemen, Messrs. Dunstan and Short, to whose ability and industry they could scarcely be too grateful; and he begged them to take notice that all he might have to say in criticism of their papers was limited to certain deductions they had drawn from a contemplation of their work, and did not in the smallest degree aim to disparage the work itself.

The results of these investigations had been placed before them by the authors themselves in a series of papers of great merit, which had been published from time to time in the *Pharmaceutical Journal*; and for present convenience he would endeavour to summarize what these gentlemen had done.

1. They examined experimentally the various methods of extracting the mixed alkaloids contained in nux vomica, and of determining the proportion in which they exist in the drug, and they supplied elaborate details of the one they considered the best, and in the course of these experiments they evolved a reliable process by which these alkaloids, strychnia and brucia, may be separated, the one from the other.

2. They reported upon the variation in alkaloidal strength of various samples of nux vomica as met with in commerce, from 3·9 per cent. to 2·74 per cent.

3. They reported upon the variation in alkaloidal strength of the tincture as met with in commerce, from 0·36 per cent. to 0·12 per cent.

4. They reported upon the variation in alkaloidal strength of the extract as met with in commerce, from 17·54 per cent. to 10·32 per cent.

5. Also that the relative proportions of the two alkaloids, strychnia and brucia, differ in different samples:—From 100 strychnia and 100 brucia to 100 strychnia and 179 brucia.

6. They reported that spirit of varying strength exerts different exhausting power on the drug, the most efficient being a mixture of 100 parts of spirit and 25 parts of water.

7. And in the light of these facts they conclude and recommend that the tincture and extract of nux vomica be authoritatively *standardized* as regards their *mixed alkaloidal* strengths, the standard they elect for the extracts being 15 per cent. of mixed alkaloids, and that of the tincture being 0·24 per cent.

Mr. Schacht continued — These results, Gentlemen, thus hastily summarized, represent a very large amount of work, and I beg to assure you, that work is of high order and deserves your careful study throughout.

I should like, however, to comment upon one or two points.

The plan Messrs. Dunstan and Short adopt and recommend for the estimation of the mixed alkaloids in the crude drug, the extract and the tincture, is described in full at page 442 of vol. xiv. of the Journal. It consists in obtaining a solution of the impure alkaloids in chloroform, washing them out as salts in acidulated water, precipitating with an alkali, dissolving the pure alkaloids in chloroform, evaporating the solvent and weighing the residue.

The method is undoubtedly accurate. A sample of the extract I here show you treated as above yielded to Messrs. Dunstan and Short 17·9 per cent. of mixed alkaloids, and to myself 18· per cent. But the process requires time and care, and a misadventure at any part of its course spoils the whole; it must be repeated from the beginning.

I have found a method of titration with potassic mercuric iodide, based upon the recommendations of Dragendorf, very nearly as accurate and much more easy of application. These are its details, as applied to the titration of the extract.

Prepare a test solution of potassic mercuric iodide by mixing 1·355 gram of perchloride of mercury with 4·98 grams of iodide of potassium and water to make 1 litre. Each c.c. of this solution precipitates 0·00184 gram of mixed strychnia and brucia.

Dissolve 1 gram of the extract to be examined in 30 c.c. of water, acidulated with 1 c.c. of hydrochloric acid, warm gently for half an hour and cool. Filter through paper and wash with water until the filtrate measures 100 c.c.

Of this solution take 10 c.c. in a small beaker and drop in from a burette sufficient of the test solution to throw down the whole of the alkaloids.

The point of completion may be determined, almost certainly, by the clearness of the supernatant liquor after stirring the whole with a glass rod, and may be confirmed by the addition of ammonium sulphide to a little of the filtered mixture which would render evident any excess of the precipitant. But the experiment is so easily and quickly performed that the result may be confirmed again and again with fresh quantities (10 c.c.) of the original solution under examination.

Of such a solution of 1 gram of the extract before you, 10 c.c. were found to require 9·7 c.c. of the test solution, and $0·00184 \times 10 \times 9·7 = 0·17848$; therefore, the sample contained 17·848 per cent. of mixed alkaloids.

This result coincides very nearly with those obtained by Messrs. Dunstan and Short, and by myself when employing the more elaborate method.

I think our authors scarcely did justice to this process as applied to the particular case before us. It may, perhaps, have received some undue laudation in respect of its power to titrate alkaloids generally, but, as I venture to repeat, in the case of the nux vomica alkaloids it appears to be reliable.

And now I wish to discuss the deductions and recommendations suggested by Messrs. Dunstan and Short as the practical outcome of their labours.

Struck by the great variation in potential activity of nux vomica and its preparations, as measured by the proportions of mixed alkaloids contained in them, they urge that these preparations, the extract and the tincture, be authoritatively standardized, and they suggest a fixed standard.

At first sight this suggestion is calculated to commend itself to general acceptance, but I find myself less pleased with it the more I examine it, and I conclude that without a great deal more knowledge than I think any one is at present possessed of, any attempts to standardize the medical potency of extract of nux vomica must be fallacious. There is no doubt that a large portion of the medical activity of the drug does depend upon the alkaloids it contains, but I am acquainted with no proof that all the rest is inert. Neither am I aware that the effect of brucia upon the human subject as distinct from that of strychnia has ever been clearly ascertained. I incline to the opinion (though I advance it with some reserve) that no physiological experiments of the kind required have ever been made with *pure* brucia, that is, absolutely free from strychnia, and that, therefore little is really known of its medical value. If we are to standardize at all, we should standardize each potential element by itself, and not a mixture of elements, one of which is of undetermined power. As this is a point that appears to me of importance, I draw your attention to this table. It is, in chief part, a copy of one given by Messrs. Dunstan and Short showing the variations in alkaloidal strength of ext. nux vomica, as met with in commerce, and the varying proportions of the strychnia and the brucia that constitute these "mixed alkaloids." The column on the right is my own and is intended to show somewhat more strongly the variations in these proportions; the figures represent the proportion of brucia to the 100 of strychnia. You will see that in the twelfth sample the two alkaloids existed in nearly equal proportions, or as 1 to 1, whilst in the eleventh sample the brucia was as over 1¾ to 1 of strychnia. I fear, therefore. that standardizing the extract by fixing its percentage of *mixed* alkaloids, with such contingencies before us, is misleading.

	Mixed alkaloids.	Strychnia.	Brucia.	Relative proportion of brucia to 100 of strychnia.
1	15·15	6·63	8·52	128
2	15·64	7·44	8·20	110
3	10·32	4·19	6·13	146
4	15·16	7·08	8·08	114
5	12·49	5·53	6·96	125
6	12·52	5·17	7·36	142
7	12·25	4·87	7·38	151
8	17·54	7·52	10·02	133
9	15·78	6·41	9·37	146
10	15·94	6·84	9·10	133
11	16·24	5·81	10·43	179
12	17·12	8·58	8·54	100

Having urged thus much against the general idea of standardizing, it may appear unnecessary to criticize the particular standard suggested by Messrs. Dunstan and Short. But doing so will serve to show another difficulty that would attend the practice. The percentage strength suggested by these gentlemen is 15; the sample before you, made with only ordinary care in the course of business in the laboratory of my own firm, contains 18 per cent. of the alkaloids. What am I to do with it to bring it to the required standard? Dilute it, perhaps, with spirit. Well, that would make it a clumsy soft mess to begin with, and it would soon dry up to its present condition of extra potency. Something else must be added to it; and that I should be sorry to sanction.

And if a sample comes out below the standard? Well, I suppose the batch must all be thrown away (for nothing in the form of alkaloid must be permitted to be added), unless, indeed, it be kept to dilute to the proper standard some future batch that turns out to be too strong.

I think considerations of the kind I have placed before you should make us hesitate before we endorse the final recommendations of Messrs. Dunstan and Short. We may thank them heartily for the good scientific work contained in their papers, but, I think, as prudent men, we should decline to follow them in assumptions that belong rather to other departments of medical authority than to that of pharmacy proper, and that are, to say the least, somewhat premature.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

A general meeting was held in the Society's rooms, on Wednesday evening, April 9. Mr. Preston, the President, in the chair.

The minutes of the previous meeting were confirmed.

The Secretary announced the following donation:—The *Pharmaceutical Journal*, from the Pharmaceutical Society.

The following gentlemen were elected members of the Society:—Messrs. J. H. Bradwell, W. Dutton, W. Clayton, John Clark.

A paper was read on—

A Plea for Botany.

BY G. A. GRIERSON.

Natural science of any kind is now recognized by all eminent authorities as being a most important factor in the training and development of the mind, and especially of that part of the mind wherein lie the powers of observation. In the words of one of our most eminent scientists,—"There is no object on which the youthful energy can be employed more worthily than in the pursuit of knowledge; no kind of knowledge can be more attractive than that which is presented by the works of creation; no source is more accessible; no fountain more inexhaustible; and there is none which affords, both in the mode of pursuing it and in its own nature, so complete or so beneficial a diversion from ordinary scholastic pursuits."

The advantages to be derived from botany may be looked at in two lights. First, from a naturalist's point of view, and, second, from a utilitarian's. Let us first listen to what the naturalist has got to say.

The famous aphorism of Lord Bacon,—"A little knowledge is a dangerous thing," has, I think, a noteworthy exception in the study of botany. For, surely, the little knowledge acquired from books by the dweller in a large town, which induces him to seek the country in order to put his knowledge into practice, is far from dangerous, either from an educational or from a physiological point of view. A science which for its study compels one to take long walks amid bracing air and refreshing scenery is surely not to be despised by him whose lot is cast in a large town amid the smoke and din of a money-making world, and who, but for an interest awakened in natural science, might never think it worth his while to leave the busy streets. Its action in strengthening and stimulating the physical powers is perhaps only equalled by its action on the mental. For quickening and developing the powers of observation I think there is no science can equal it, except, perhaps, zoology. The importance of the proper training and development of these faculties cannot be overestimated by anyone who aspires to the position of a cultured pharmacist, or, indeed, by the member of any profession, the complete success of which depends on observation and experiment. If these faculties were only better developed how many little points would be noticed in the business of every day which might lead to important results, for it is the acute observers and patient experimenters of past years who have placed technical knowledge in the position which it now occupies, and it is this technical knowledge, this applied science, which has given to England the position which she now occupies among other nations.

But besides these lasting advantages, consider the exquisite pleasure to be derived from the study of Nature. "A thousand wonders people the leaf; a museum of curiosities finds a home in the water drop; and the pleasure derived from a search in Nature's fields is one that no accident of life can mar, and no misfortune of existence take away." It is next to impossible for a thinking being to enjoy a ramble in the country or a sojourn by the seaside without a knowledge of the wonders which surround him on every side, and he who in some country ramble is questioned by some inquisitive youngster as to the name of some common plant will, I think, admit that even a little knowledge is better than none at all. Surely none of us aspire to the position of him of whom the poet sang—

"A primrose by the river's brim
A yellow primrose was to him,
And it was nothing more."

Nothing, surely, could impress us more with the power of plants in calling forth the best feelings of our nature than a story which is related of Linnæus, the "father of botany." It is related of him that on landing in England, and passing a heath of yellow flowering gorse, he fell down upon his knees and thanked God for making, in the common road and field, flowers so beautiful.

Let us now look at our subject from a utilitarian point of view, and look first at the uses of plants themselves and then at the uses of the study of plants.

Plants play a very important part in the cycle of organic life. Under the influence of sunlight the chlorophyll of the leaf decomposes the carbonic anhydride of the air, utilizing the carbon to build up its tissues, and giving back to the air the vitalizing oxygen. But for this wonderful provision the carbonic anhydride, which is continually exhaled from animals, would gradually accumulate in our atmosphere, and "the cessation of all vital phenomena" would merely be a question of time. But besides CO_2 plants absorb, from the air by which they are surrounded and the earth in which they grow, ammonia and water. These three substances are so acted on by the plant as to be converted into starchy and albuminous bodies, which we use as our daily food in the form of barley, wheat, oats, etc. The ligneous or woody portion of the plant, not being soluble in the human stomach, has to pass through an intermediate stage before we can use it as food. This intermediate stage is found in the herbivorous animals, such as the ox and sheep. These, from their great digestive powers, convert it into fatty matters, which reach us in the form of beef, mutton, etc., and are, I think, much appreciated, irrespective of the fact that their elements once existed in the form of grass. The influence which plants have on the rainfall of a country is, I think, too well known to require any comment.

Now let us look for a few minutes at the advantages to be derived from a study of those plants which play such an important part in the economy of Nature. "Nothing is more short-sighted than the *cui bono* cry of the ignorant against investigators in science. It is as short-sighted as the remark of Savarino, when he said:—'He who discovers a new dish does more for humanity than he who discovers a star,' forgetting that to astronomy we owe navigation." But exactly as navigation is an outcome of astronomy, or medicine an outcome of physiology and pathology, so is materia medica an outcome of chemistry and botany. We cannot expect to understand any science thoroughly without first grasping the principles on which it is founded. Now, materia medica is the science with which the experienced pharmacist is expected to be intimately acquainted, and this alone ought to be sufficient reason for botany commanding a larger share of attention than it does.

Professor Huxley, in speaking of the influence of science on the business of every day, says:—"As industry attains higher stages of its development, as its processes become more complicated and refined, and competition more keen, the sciences are dragged in one by one to take their share in the fray; and he who can best avail himself of their help is the man who will come out uppermost in the struggle for existence, which goes on as fiercely beneath the smooth surface of modern society as among the wild inhabitants of the woods." But some cynic may say, "We do not deny the advantages of chemistry and astronomy in the practical work of the world, but botany is only for those who have very little to do, and require some 'hobby' to keep them from moping." I should not for one moment think of refuting this by trying to show you all the benefits which have been conferred on the world by the study and application of the science of botany, simply because my knowledge is not extensive enough, and, besides, it would be rather beyond the scope of a paper such as this. But let us just glance at some of the benefits it has conferred on the science of medicine, with which we have the honour to be connected.

To enlist you in the cause of histological botany, I think it is only necessary to point you to the work done by Mr. Howard in the study of cinchona, and Schleiden in the study of sarsaparilla. But perhaps this is more the work of the specialist than of the ordinary pharmacist, time being an important factor in such investigations. Every pharmacist, however, is expected to know the difference between the leaves of such plants as belladonna, hyoscyamus, hemlock, stramonium, and such fruits as caraway, hemlock, dill, anise. Now, underlying all such knowledge, is a botanical principle, which must be understood before it can be applied. Is it not much more reasonable to get up the minutiæ of such knowledge from a study of the works of Nature than from mere book work? I think the most confirmed votary of practical business cannot but acknowledge that plants such as belladonna, hyoscyamus and hemlock are not only much more easily studied, but are much more interesting to study when growing "amid the wild magnificence of Nature," than when dry and lifeless they ornament the walls of a museum, or contribute to the profits of a pharmacy.

All materia medica books teem with botanical terms, and lead the student to think that botany is merely a science of hard names, a means to an end, not a study which can of itself yield both instruction and amusement. It is astonishing how easy the study of terms becomes, if there is only interwoven with it the element of practical work. The pleasure of finding out the name of some new plant by the correct interpretation of numerous hard terms, contained in the description of it, requires to be experienced in order to be appreciated. It is astonishing how a single success in commencing leads the aspiring student to explore further and further the "mine of Nature."

A very large portion of our materia medica is composed of plants not indigenous to our own country. Why is this? Probably one explanation is found in the fact that in warmer climates than our own the natural juices of plants are more thoroughly developed, as is the case with hemp. But I venture to think another reason is to be found in the fact that our native plants do not receive the study they merit from those who are, or should be, competent to make observations, and to deduce from these observations conclusions which might result in the introduction of many really valuable indigenous plants into our materia medica. Of late, several competent observers have come into the field, with the result that certain common wayside plants, known to the herbalist of old, but since discarded for want of more thorough investigation, have again been recognized as valuable from a therapeutical point of view. Dr. Quinlan, an enthusiastic worker in this field, has shown us the value of *Verbascum Thapsus* in phthisis, of the common plantain or ribwort as an astringent of no mean powers, and of *Galium aparine* or common goose-grass in the form of a poultice for ulcers; and quite recently the value of a yellow oil obtained from St. John's wort in the treatment of bedsores has been demonstrated by another worker in the same field.

But apart even from such motives as these, botany is worth studying if it were only for the glimpses it gives us of some of the internal workings of Nature. Like all other sciences, it is worth studying for its own sake, even if we could see no direct benefit to be conferred on the human race by its study. "All that science can achieve is a perfect knowledge and a perfect understanding of the action of natural and moral forces. Each individual student must be content to find his reward in rejoicing over new discoveries as over new victories of mind over reluctant matter, or in enjoying the æsthetic beauty of a well ordered field of knowledge, where the connection and the filiation of every detail is clear to the mind; and where all denotes the presence of a ruling intellect, he must rest satisfied with the consciousness that he too has contributed something to the increasing fund of knowledge on which the dominion of man over all the forces hostile to intelligence reposes."

Now that spring has got well advanced, we are almost in the midst of those innumerable gems in whose cause I have tried to enlist your sympathies.

"Scattered by Nature's graceful hand,
In briary glens, o'er pasture land,
The fairy tribes we meet;
Gay in the milkmaid's path they stand,
They kiss her tripping feet."

Few towns are so favourably situated for the study of botany as Sheffield. It is in the centre of a district teeming with all orders of plants, and all that is wanted to secure them and obtain from them lessons to carry through life with us is a little time and inclination. The former element is generally rather a scarce one with chemists' assistants and apprentices, and so prevents the proper development of the latter; but the inclination, if present, will generally manage to find the time, even if at some inconvenience. At all events, let us cultivate the inclination, and perhaps "the powers that be" may gradually come to see that it is to their own interest to foster the spirit of scientific inquiry, and to grant a little more time for its due development.

A discussion ensued, and at the conclusion a hearty vote of thanks was awarded Mr. Grierson, on the motion of Mr. Thacker, seconded by Mr. Smith, for his interesting and instructive paper.

LIVERPOOL CHEMISTS' ASSOCIATION.

The twelfth general meeting of the thirty-fifth session was held at the Royal Institution, March 27. Mr. Edward Davies, President, in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations to the Library were announced:—The *Canadian Pharmaceutical Journal*, from the Editor; The *Pharmaceutical Journal*, from the Society; The *Pharmaceutical Record*, New York, from the Editor, and the 'Thirty-first Annual Report of the Free Public Library and Museum and Walker Art Gallery, 1884,' from the Council of same, and a copy of the 'New Pharmacopée Française,' 1884, from Mr. A. C. Abraham, F.C.S.

A vote of thanks was passed to the donors, and Mr. Conroy moved, Mr. Parkinson seconded, and it was resolved:—"That a special vote of thanks be given to Mr. A. C. Abraham for his handsome donation to the Library."

The President stated that a complimentary dinner had been given to Mr. A. H. Mason, F.C.S., their late Vice-President, at the Stork Hotel, Queen Square, on Thursday, March 20, which was attended by forty-four gentlemen, and proved, in every way, a very gratifying success; also that Mr. Mason had that day sailed for Canada, bearing with him the best wishes of the Council and members of the Association.

Mr. J. C. Hornblower showed a lump of stone, weighing about 2 lbs., which had been found in an original package of gum assafœtida. The stone had evidently been faced with the gum and passed off as assafœtida.

Mr. Davies thought the stone was calcium carbonate.

Mr. Conroy said it was not at all an uncommon thing to find these stones as adulterants in packages of assafœtida, and he had known, in one instance, as much as 60 per cent. of the contents of an original package consisting of these stones. He considered they were indebted to Mr. Hornblower for drawing attention to the matter.

Mr. Parkinson drew attention to some oil of sweet almonds he had in his store, in which a sort of gelatinous matter was floating, and desired an explanation.

Mr. A. H. Samuel said it was no doubt mucilage, which was found in most vegetable oils, and was usually removed in the process of refining.

The President then called upon the Honorary Secretary to read the paper of the evening, contributed by Mr. M. Whitley Williams, of London, entitled,—

NOTES ON THE AMMONIA PROCESS FOR ESTIMATING NITRIC ACID.

BY M. WHITLEY WILLIAMS.

Some four or five years ago I was led to make some experiments on the transformation of nitric acid into ammonia by observing, in the course of some analyses, very peculiar variations in the rate at which the nitric acid was reduced. The method I was employing was based upon the too little known fact, which we owe to Dr. Gladstone and Mr. Tribe, that zinc when coated with precipitated copper has its chemical activity so highly increased as to be able slowly to decompose distilled water at ordinary temperatures, a decomposition which results in the evolution of hydrogen and the formation of zinc hydrate. In presence of a dissolved nitrate the hydrogen is no longer evolved, at all events as gas, but the nitrate is reduced to nitrite and almost simultaneously the latter is transformed into ammonia.

When we consider that to do this we add nothing to the solution beyond a mere trace of hydrate of zinc, the reaction will obviously strike us as so singularly neat and clean (from a chemical point of view) as to offer peculiar advantages as a means of analysing nitrates. Provided always that it can be proved stoïchiometrically correct and can be made sufficiently rapid to be practicable.

To ascertain its stoïchiometric accuracy was my first care, and in this I was so far convinced of the completeness of the transformation as to feel satisfied that it was effected with much greater nicety than the methods of estimating ammonia permitted me to prove. A quantity of nitre sufficient to yield 1·685 parts of ammonia was successively by the most rigid method proved to yield 1·67, 1·69, 1·68, 1·69, 1·68, 1·68, 1·68, 1·70 and 1·67 parts of ammonia, a result which of itself is sufficiently creditable even to the methods of estimating ammonia.

It would take more time than I can now spare to conduct you through the experiments I made to ascertain the precise conditions under which the transformation takes place with the greatest rapidity. I cannot even now pretend to be master of them all, but so far as the usual necessities of the analyst are concerned, I believe the information obtained to be sufficient. Cold retards and heat greatly expedites the reaction; alkalies and particularly alkaline and earthy carbonates also retard it, while free carbonic acid or the merest traces of other acids make it proceed at a rate quite marvellously increased when we take into account the small amount employed. Thus, a nitre solution requiring about fifteen or twenty hours for complete reduction, in presence of carbonic acid was practically reduced in about two hours, while less than one-tenth per cent. of a mineral acid in solution completed the reduction in an hour.

But the most unexpected result was that small quantities of neutral alkaline or earthy salts had also an enormous accelerating influence. Thus one-tenth per cent. of sodium chloride about quadrupled the rate.

It is clear that with this information the analyst can at will obtain any reasonable rapidity desired. Let him use an elevated temperature, add either carbonic or other acid, or if he please a little common salt, or further still let him remove or decompose alkaline or earthy carbonates, and his reaction can be completed within an hour to a certainty. In the analysis of natural waters it is found that dissolved carbonate of lime has an extraordinary power of retardation. To transform this into an acceleration it is only necessary to add a little crystal of oxalic acid, the lime is removed out of the sphere of action and the liberated carbonic acid with any excess of oxalic acid then serves the most useful purpose.

Since I published an account of this work in 1881, the process has grown into much favour and has attracted much criticism, of which some little is naturally unfavourable; yet the general utility of the method has, I am happy to say, been invariably recognized, and I doubt not sincerely felt, and for a reason sufficiently well founded in human nature. The method is so easy. To estimate the nitrates, say in a natural water, place some strips of clean zinc foil slightly crumpled in a wide-mouthed stoppered bottle, about 1 square decimetre to 300 c.c. of the water, and cover it with a 3 per cent. solution of crystallized copper sulphate solution. When the zinc has acquired a copious black but firmly adherent coating of copper, the solution is drained off and the copper-coated zinc gently washed by covering it two or three times with water. A portion of the water to be analysed is then poured on it to displace adhering distilled water and the bottle then nearly filled with it, the stopper inserted, any acid or salt added at the discretion of the analyst and the whole allowed to digest in a warm place till a little of the solution withdrawn gives no reaction of nitrous acid by Griess's metaphenylene diamene or naphthylamine test. The disappearance of the last trace of nitrous acid marks the end of the reaction. Or the analyst who does not care to trouble himself with testing may simply leave the digestion over a single night, feeling assured of a complete reduction in the morning. The titration of the ammonia is then made upon a measured volume of the fluid, diluted if necessary, or distilled, if the Nessler reagent produces an unavoidable turbidity as happens with some waters, particularly those containing much sulphates or certain other salts.

And here I would remark upon the extreme complexity of the conditions affecting the process termed familiarly *nesslerization*. Very few who use the process have reflected much about them, but many salts exercise influence, those even in the reagent itself affecting its sensitiveness and accuracy, while the proportion of oxide of mercury dissolved plays an essential part in the reaction. As a rule it may be laid down that the best conditions are those which most nearly approach to absence of all negative radicals save iodine and the maximum of mercuric oxide. Again, equality of temperature in the solutions is necessary, and I have observed that with the ordinary reagent the lowest temperatures appear to give the most delicately comparable tints.

I would further remark upon the very unsatisfactory nature of the glasses usually employed in this process. Seldom are two so exactly similarly "barrelled" as to show no difference when two apparently equally tinted fluids are transposed into each other's vessels. I have recommended for precise purposes, and always used, exactly cylindrical vessels made from glass cylinder with plate glass ends cemented with canada balsam, or clipped on.

These may be divided lengthwise into millimetres, and occasionally used for comparing the depths necessary to produce equality of tint. For the metaphenylene diamine estimation of nitrous acid this is peculiarly well adapted, and the results appear to suffer little or no error through the colour being produced in somewhat different strengths of solution.

Commenting on my method in the *Analyst* some time ago, Blunt has made a suggestion well worthy of trial. He suggests that in analysing a water containing lime a certain quantity should be treated with oxalic acid (say about $\frac{1}{20}$ per cent. A portion placed on the coppered zinc, and then instead of using distilled water for the comparison fluid, an equal quantity of the prepared water should be employed. In case of turbidity, he informs us that in this way an equal turbidity being produced in both fluids the determination is not interfered with.

And now my time is short and I cannot refer to some new work on the subject of nitric acid with which I have recently been engaged. It refers to the frequent presence of nitric acid in distilled water, which I believe to have traced by the aid of this process to its proper source. What that source is I must leave unsaid for the present, for I believe you would most unhesitatingly, and I think most properly, reject if I did not substantiate it with a suitable and detailed account of my work; but with your permission I will on a future occasion endeavour personally to show you by experiment.

Mr. A. H. Samuel, F.C.S., moved that a hearty vote of thanks be accorded to Mr. Williams for his valuable communication.

Mr. Ward, in seconding the vote, said he was much struck with the accuracy of the results obtained by the new method with such a small an amount of labour.

The discussion was continued by Messrs. A. C. Abraham and Conroy, and the vote was carried by acclamation, and the proceedings terminated.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The twelfth meeting of the session, being the Annual Business Meeting, was held on the evening of Wednesday, April 2, at 9.15. Mr. C. F. Henry, President, in the chair.

The minutes of last meeting having been read and confirmed, the Chairman called upon the Treasurer to read the financial statement, which showed an increase in the income from annual subscriptions of £1 19*s*., a balance of £9 18*s*. 7*d*. being left in the Treasurer's hands.

The Assistant-Secretary then read the annual report, in which the Committee congratulated the Association on the gratifying increase of membership. Last year there was an increase of fourteen. This year the membership is further increased by seventeen. The number of members on the roll, last year being seventy-two, is now eighty-nine. It is worthy of note that the Association has almost doubled its membership in three years. Of those who joined the Association this session the larger number are apprentices, and it is hoped that this is a sign that an increasing number of candidates will become aspirants for the honours of the two prize schemes now conducted by the Association. The meetings were again held at fortnightly intervals, and the syllabus carried out in its entirety. All the papers had been contributed by members of the Association. A new and successful feature had been introduced, this session, in the form of papers on "Chemistry" and "Botany," intending to guide those preparing for the examinations of the Pharmaceutical Society. On two occasions the Association had been honoured by the presence and expressions of goodwill from members of the North British Branch. The open meetings held in November and January had been largely attended, showing how they were appreciated. The ordinary meetings, as a whole, had been well attended, and an increased desire to carry on the work of the Association had been shown by the members. A memorable event of this session had been the institution of the "Ainslie Pharmacy Prize," the outcome of the handsome gift of Mr. W. Ainslie. There are two prize schemes conducted by the Association, and the successful results of the examinations were a matter for congratulation. The finances of the Association continue in a most satisfactory state. The Committee recorded its indebtedness for most valuable assistance received from the esteemed Secretary of the North British Branch. The report concluded by expressing the hope that the Association will continue to make that satisfactory progress in the future which has distinguished it in the past.

The financial statement and report having been adopted, it was decided to forward £1 1*s*. to the Benevolent Fund of the Pharmaceutical Society.

A vote of thanks was heartily accorded to the retiring office-bearers and Committee.

The office-bearers and Committee for next session were then elected as follows:—President, Mr. W. S. Turnbull; Vice-President, Mr. J. R. Hill; Secretary Mr. W. Pirie; Assistant-Secretary, Mr. W. H. Duncan; Treasurer, Mr. J. B. Dunlop; Members of Committee, Messrs. Boa, Bowman, Hendry, Henry, Manson, Robbie, Robertson and Stephenson; and as Members of Prize Committee, in addition to the President, Vice-President and Secretary, there were elected Messrs. Boa, Henry and MacEwan.

After other business had been disposed of, the proceedings terminated.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION

At a meeting of the above Association, held on April 9, Mr. C. Parkinson (President) in the Chair, a paper on "Operative Dentistry" was read by Dr. Albert J. Kutz, D.D.S.

After a few introductory remarks, the author alluded to the prevention and cure of "Caries," the great method of prevention being to keep the teeth clean; for this purpose the author recommended that the teeth be cleaned four times a day at least, once after each meal and thoroughly rinsing the mouth before retiring being necessary. In the morning a good tooth-powder should be used and after each meal the particles of food should be removed from between the teeth with a quill tooth-pick; metallic picks should not be used as they are liable to damage the enamel. The best method of applying the tooth-brush was then described, and the occasional use of a silk thread with powder on it and drawn between the teeth was recommended. The process of filling or stopping teeth was then given in detail. The materials used for stopping were next mentioned, gold being specially alluded to; the two kinds of gold in use being the adhesive and non-adhesive. The gold is supplied to the dentist in the form of leaves of various thickness and also in soft spongy masses called crystalline or sponge, plastic and shred, all of which are very adhesive. Cohesiveness is the name given to that quality of gold, by which one portion by pressure becomes so incorporated with another as to make a mass about as solid as coin. The author then mentioned the cases in which adhesive or non adhesive gold was the most preferable for use, giving the reasons.

A discussion followed, in which the President, Messrs. Axford, Carter, Cracknell and Millhouse took part.

A vote of thanks to Dr. Kutz terminated the proceedings.

Parliamentary and Law Proceedings.

Prosecutions under the Pharmacy Act.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* MAY.

At the Edmonton County Court, before J. T. Abdy, Esq., LL.D., Judge, on Tuesday, April 8, the Council of the Pharmaceutical Society of Great Britain sued R. May, of Ponder's End, to recover two penalties of £5 each, first for keeping open shop for the retailing, dispensing or compounding of poison, and second for taking, using or exhibiting the name, style or title of "chemist," contrary to the provisions of the Pharmacy Act, 1868.

Mr. Wallace, instructed by Messrs. Flux, Son and Co., appeared for the Society. Mr. Avery, solicitor, appeared for the defendant.

It was admitted by defendant's solicitor that defendant had sold poison and used the title of "chemist," thereby incurring the penalties sued for, and he only addressed the Court with reference to defendant's character.

His Honour held that he had not to take into account the defendant's character. Defendant had incurred the penalties sued for, and he gave judgment for the plaintiffs accordingly,

And upon application, His Honour held that the case was one of public interest and for the public benefit, and therefore gave judgment for plaintiffs with costs on the higher scale.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* BLYTHER.

At the Edmonton County Court, before J. T. Abdy, Esq., LL.D., Judge, on Tuesday, April 8, the Council of the Pharmaceutical Society sued G. F. Blyther of High Road, Tottenham, to recover two penalties of £5 each, first for keeping open shop for the retailing, dispensing or compounding of poison, and second for taking, using or exhibiting the name, style or title of "chemist," contrary to the provisions of the Pharmacy Act, 1868.

Mr. Wallace (instructed by Messrs. Flux, Son and Co.) appeared for the Society. The defendant did not appear.

Evidence was given that a prescription which contained "strychnia" was made up at defendant's shop on the 15th ult., that upon the bill in which the bottle was wrapped were the words, "Sold by Wall, Family and Dispensing Chemist, High Road, Tottenham," and that there appeared over defendant's shop the words, "Blyther, successor to the late W. J. Wall."

Proof of the death of Mr. W. J. Wall having also been given, and that there was no chemist of the name and address of "Wall, High Road, Tottenham," His Honour gave judgment for the plaintiffs for the two penalties with costs on the higher scale.

Poisoning by Prussic Acid.

An inquest was held at Northallerton on the body of Dr. Henry Brown, on April 12. Mrs. Brown, the wife of the deceased, stated that on Thursday evening she left him in the surgery, writing. As he did not return she sent for Dr. Richmond, who paid a visit to the surgery, on pretence that he wanted to borrow a syringe. Dr. Brown said he would return home in a quarter of an hour. Dr. Richmond said that later in the evening he was standing in the street, and saw Dr. and Mrs. Brown walking arm in arm. After midnight he was called out of bed by Mrs. Brown, and proceeded at once to her residence. He found Dr. Brown lying on the sofa, breathing heavily. He instructed them to send for another medical man. He put his fingers down Dr. Brown's throat to make him vomit, but failed. His eyes were fixed. He detected a strong smell of prussic acid. He applied the stomach pump, and washed the stomach out. The fumes of prussic acid were so strong that he had to turn his head away. Dr. Brown died at half-past twelve o'clock. He (Dr. Richmond) sent for the police. He found upon the mantelpiece a bottle of prussic acid. He went with the police-constable to Brown's surgery, and found the letter that he had been writing. The terms of the letter left no doubt that the writer was insane. The cause of death was poisoning by prussic acid. Inspector Beswick gave confirmatory evidence, and the Jury returned a verdict in accordance with the medical evidence.—*Leeds Mercury.*

ANSWERS TO CORRESPONDENTS.

Erratum.—On p. 812, col. ii., line 14 from top, the name of the speaker should be "Mr. Gravill," instead of "Mr. Hadfield."

F. Moore is recommended to experiment with some varieties of "aniline blue" until he obtains the shade that he requires.

Mr. McBeath is thanked for his communication.

A. E. I.—We have never heard of the existence of such a poisonous principle and should be inclined to believe that a mistake has been made. With respect to the proprietary article mentioned we know of no other means of ascertaining its composition than by analysis.

David.—*Vaccinium Myrtilus.*

Omega is recommended to consult a solicitor.

H. P. F.—If we have been successful in deciphering your handwriting, the phrase appears to be a quotation from a well-known litany, and with a moderate knowledge of Latin there should be no difficulty as to its translation.

Communications, Letters, etc., have been received from Messrs. Hocken, Yewdale, Symes, Edwards, Moderate Apprentice, J. W. P., X. Y. Z.

"THE MONTH."

Considering the comparative immunity that has been hitherto enjoyed in these islands from earthquake shocks and the consequent absence of any provision for obtaining accurate and systematic seismological records, it is not surprising that the reports of the phenomenon which has caused so much alarm in the eastern counties during the last week should be characterized by extreme vagueness as to its occurrence and duration. Still, it may be expected that further light will be thrown upon these points, and, in fact, an interesting contribution in this direction has been already contributed to the *Leeds Mercury* by Messrs. Reynolds and Branson. Those gentlemen state that upon examining the diagram traced by their recording barometer on Tuesday they found that between 9.15 and 9.30 a.m. the ink-line thickened suddenly, whilst a gentle movement downwards was shown. A thickened line continued to be produced until 1.30 p.m., when the tracing regained its ordinary character. During this period of four hours six distinct undulations were registered, the greatest of which measured 0·025 in.

An ingenious modification of the process of bleaching has been introduced by Mr. J. B. Thompson, which promises to effect a great saving of time and labour. In the ordinary process the goods to be bleached are usually first boiled with lime for about seven hours, after which they are washed in water and "soured" by steeping them for four or five hours in water acidulated with hydrochloric acid. Then after another washing they are boiled for nine hours in soda ley, again washed, and next submitted to the "chemicking" process, which consists in steeping them in a dilute solution of chloride of lime for four hours. With the exception of the lime boiling this treatment is repeated several times, involving in the case of cotton goods some sixteen distinct operations, extending over a period of five to eight days. In Mr. Thompson's process the "souring" and "chemicking" operations are combined in one. The goods are placed in an air-tight "kier," connected on the one hand with a vessel containing a dilute solution of chloride of lime, and on the other with a gas-holder containing carbonic acid gas. A charge of the bleaching solution is first pumped in and the goods are allowed to soak in it during five minutes, after which communication is opened with the gas-holder and the liquor is run out from the bottom of the "kier." The partial vacuum thus created causes an inrush of the gas, and the goods are subjected to its action for fifty-five minutes, by the end of which time the whole of the chloride has been decomposed in contact with the fibre of the cloth. Bleaching liquor is then again pumped into the "kier," driving the gas back into the gas-holder, and these processes are repeated alternately according to the necessity of the case. Lastly, the goods are passed through a solution of triethylrosaniline and oxalic acid, which removes the natural faint yellow tinge from the cotton.

The interesting results obtained by Grimaux and Gerichte, establishing the close relationship existing between morphine and codeine, have induced Mr. W. C. Howard to take up the examination of thebaine, another opium alkaloid in which nitrogen and oxygen are present in the same proportions as in those two, the empirical formulæ by which the three are represented being—morphine $C_{17}H_{19}NO_3$, codeine, $C_{18}H_{21}NO_3$, and thebaine, $C_{19}H_{21}NO_3$ (*Berichte*, xvii., 527). Attempts made to add hydrogen atoms to the thebaine molecule so as to raise it to a homologue of morphine were unsuccessful. It was observed, however, that when thebaine was heated in a closed tube to about 90° C. with fuming hydrochloric acid, there occurred after a short time an abundant separation of crystals, whilst upon opening the tube there was an escape of a combustible gas. These crystals proved to consist of the salt of a new base, represented by the formula $C_{17}H_{17}NO_3$, and called "morphothebaine" to indicate that it is a decomposition product of thebaine as well as its probable near relationship to morphine. Whether in the decomposition that occurs one equivalent of HCl is taken up and one equivalent of C_2H_5Cl evolved, or two equivalents of HCl are taken up and two equivalents of CH_3Cl evolved, has not yet been determined, though from the fact that an ethoxyl group has not yet been observed in organic bases the latter is thought most probable. On the other hand, only a monoacetyl compound was obtained, though this may be attributable to one of two hydroxyl groups being more readily acetylized than the other, as has been observed in the case of morphine (see before, p. 603.) An analogous compound was obtained when hydrobromic acid was substituted for hydrochloric acid. It may be remembered that Grimaux looks upon thebaine as morphine-ethylether ($C_{17}H_{18}NO_2 \cdot OC_2H_3$), though it has not yet been derived from morphine in this way.

Following up the investigations of Drs. Frazer and Brown in this country and many observers abroad, upon the relation between chemical constitution and physiological action in organic compounds, Dr. Stolnikow, of St. Petersburg, has been experimenting to ascertain the importance of the hydroxyl group in certain poisons (*Zeits. f. phys. Chemie*, viii., 252). It has been shown by Grimaux, and confirmed by Hesse and others, that morphine resembles a phenol in constitution, and that it contains a hydroxyl group, the hydrogen of which is replaceable by the methyl group (CH_3) to form codeine, which may therefore be considered the methyl ether of morphine. With this change, however, the physiological properties of the compound are modified, the narcotic action giving place to a tetanic action. Further, if, instead of the methyl group, the ethyl group (C_2H_5) is introduced, forming a new body that has been named codethyline, the tetanic action becomes more pronounced. Dr. Stolnikow's experiments were directed to ascertaining the effect when instead of an active alcoholic group an indifferent group is substituted, using what he calls a "morphine sulphuric acid ether," which is morphia minus a hydroxyl group and plus a residue of sulphuric acid:—

Morphine. . . . . $= C_{17}H_{18}NO_2\ (HO)$.
Morphine sulphuric acid ether $= C_{17}H_{18}NO_2\ (SO_4H)$.

Comparative experiments were also made with phenol, pyrogallol and resorcin, and with derivatives of those bodies in which a similar substitution had been effected. The general conclusions arrived at are that the toxicity of the original bodies is intimately bound up with the hydroxyl groups they contain; and when these are replaced by the indifferent sulphuric acid group, poisons are obtained which are far weaker, but which, as in the case of morphine and morphine sulphuric acid ether, are not at all altered in their nature.

The marked success that has attended the use of the oleates has induced Dr. Shoemaker to experiment with fresh compounds, and he reports (*Med. Bulletin*, vi., 38) that he has obtained valuable results from the use of the oleates of nickel and tin. The nickel oleate is prepared by the double decomposition of nickel sulphate and sodium oleate. It is described as a green, amorphous, waxy, tasteless substance, having a most decided astringent action, almost bordering upon the effect of a caustic. In cases of chronic eczema of the extremities, where the skin was hard and leathery, it is said to have given good results, and it is now being tested upon old ulcers and cancerous affections of the skin. An ointment is used of the strength of 15 grains of the oleate to 1 ounce of lard. The tin oleate, as prepared by the double decomposition of tin chloride and sodium chloride, is greyish yellow, of an unguent consistence and has a marked metallic taste. It has been found of great utility in giving lustre to diseased nails that have been abnormal or deficient in growth, and to assist by its local action in overcoming split and soft conditions of nails that often follow certain skin affections and external injuries. Combined with a little carmine, it is said to form an elegant toilet article, imparting a beautiful polish to the nails, and by its astringent action modifying the ragged and attenuated state of the skin at their base which gives rise to the troublesome affection of "agnails."

Dr. Lewis states (*Med. Bulletin*, vi., 46) that the odour of iodoform is "almost destroyed" by an admixture of an equal quantity of oleate of zinc. As the application of preparations of zinc has been suggested in many cases in which iodoform is used it is thought that this combination may be advantageous, especially where iodoform is found too irritating to apply alone.

Aluminium and its compounds are affirmed by Dr. Pick (*Med. Bulletin*, vi., 62) to constitute a most effective remedy against pulmonary tuberclosis, this opinion being based on experiments upon rabbits, as well as observations in clinical cases. In one of the latter, where infiltration of the apices of the lungs had occurred, removal of the lesion and all morbid symptoms is said to have followed the administration of aluminium in the following form:—Metallic aluminium, 8 grams; aluminium hydrate, 5 grams; calcium carbonate, 5 grams; gum tragacanth, q. s. Divided into sixty pills, one pill being taken three times a day.

The disagreeable taste and persistence of the odour in the breath which appear to be serious inconveniences attending the adminstration of paraldehyd, are calling forth the ingenuity of German dispensers. Herr Sutter (*Pharm. Zeit.*, April 9) says that he finds rum to be the most advantageous corrigent for masking the taste, and he gives the following formula which he says yields a mixture resembling cold punch:—

℞ Paraldehyd, 100
Jamaica Rum, 150–200
Tinct. Cort. Citri vel Aurantii Rec., 10
Syr. Simp., 300
Aquæ, 1390–1440.

Dose 100 grams. For the adminstration of paraldehyd as a clyster, he recommends a mixture in the proportion of one part of paraldehyd to two parts of olive oil. Herr Hellwig speaks favourably of two mixtures, (*a*) paraldehyd, 3; ol. oliv. 15; ol. menth. pip. gtt, 3; and (*b*) paraldehyd, 3; spiritus, 6; syr. simp., 8; and tinct. vanill., 2. But he prefers an emulsion of paraldehyd, 3; mucil. gum. acac. and syr. cort. aurant. āā 8, with the addition of two or three drops of ol. menth. pip.

M. Pierre Vigier has called attention to a subject which is worthy of being followed out both by prescribers and pharmacists. He points out that certain tinctures when mixed together in a prescription are likely to give rise to precipitates which may affect to a considerable extent the strength of the mixture. Thus a resinous tincture made with 80 or 90 per cent. alcohol will have its resinous matter precipitated by alcohol of 60 per cent. In other cases some of the constituents of a weak tincture may be thrown down by a stronger one. In rarer cases, as in that of tincture of calumba and tincture of cinchona, where tinctures of equal strength are mixed, a precipitate will be formed (*Practitioner*, p. 294). This will probably be especially the case where tinctures containing tannin are prescribed with other liquids containing an alkaloid such as ipecacuanha wine.

A new use for salicylic acid is coming to the front, Dr. J. C. Ogilvie Will (*Brit. Med. Journ.*, March 29, p. 602) describes a case of thickened epidermis of the foot, in which the whole anterior of the foot had become in two months like hippopotamus hide, but was completely cured in three weeks by the use of salicylic acid plaster. The advantages of salicylic acid in curing corns are well known. Dr. Will thinks that there is a very wide field of usefulness for this agent in some morbid conditions of the skin, the treatment of which has hitherto proved extremely difficult.

In the *Brit. Med. Journ.* (p. 605), a case of opium poisoning, in which other remedies had failed, was cured by the subcutaneous injection of $\frac{1}{60}$ grain doses of sulphate of atropine. The patient had taken a quantity of laudanum and paregoric, together, equal to 17 grams of opium.

Hydrochlorate of cocaine has been tried with apparent success by Aschenbrandt in the treatment of exhaustion arising from sunstroke, loss of blood and diarrhœa. In all the cases, particularly in those of the last-mentioned disease, the results obtained were such as to render further trials of this alkaloid desirable. The dose used was from 5 to 20 drops of a 1 per cent. solution (*Therapeutic Gazette*, p. 111, from *Deutsche medicinische Wochenschr.*).

The use of bichloride of mercury as an antiseptic appears to be increasing in favour. Dr. R. Caeestatt, of Uruguay, in the *Münchener Intell. Blatt* (March, 1884) recommends the topical application of a solution of 1 part in 10,000 in the treatment of diphtheria, the part affected being painted every hour with the sublimate solution, using a fresh feather or brush each time. At the same time he gives chloral in larger or smaller doses and disinfects the patient's room by sprinkling the floor with a 2½ per cent. solution of carbolic acid (*Med. Press*, April 9, p. 340). It may be useful to point out that in the abstract from which this quotation is made 1 part in 10,000 is incorrectly stated to be about a gram to the pint.

Dr. Quinlan (*Brit. Med. Journ.*, April 5, p. 664) now recommends the mullein (*Verbascum Thapsus*) to be smoked as a remedy for cough. In a case which he has recently recorded considerable relief was afforded by its use in this way. A sample of the plant was lately found to contain belladonna leaves, as well as other leaves which were not those of *Verbascum Thapsus*. It is desirable, therefore, before the entire credit is given to mullein that careful experiments should be made with selected leaves of that plant.

Dr. Chèvon, in *Le Progrès Médical* (Feb. 23), has recommended veratria as a prompt remedy for pruritus, whether arising from prurigo, urticaria, eczema, herpes, or without any eruption at all. For this purpose he uses an ointment of 1 part of veratria to 120 of lard, but when the pruritus is general he prefers the internal administration of the alkaloid, and gives it in the form of pills. Two centigrams of the alkaloid are made into ten pills with liquorice powder, the dose being one pill three times a day, an additional one being given each successive day until a maximum dose of six is reached (*Med. Times*, April 12, p. 509).

Dr. Hicks, writing in the *New York Medical Journal*, expresses his surprise that coca is so seldom employed, and states that he has found it useful in backache, with high-coloured urine, and excess of uric acid and urates; in short breathing from weakness of the muscles of respiration; in palpitation due to dilatation or weakness of the muscles of the heart; in the craving for alcohol, which it destroys; in headache resulting from over-exertion; and in sick-headache, when given in small doses.

Dr. Bury Hart, led by the statement of Dr. Matthews Duncan that the vomiting of pregnancy is probably influenced by the liver, has tried the effect of iridin, which he states in eight cases out of nine has proved effectual. The dose given has been 2 grains, taken at night and followed by a saline aperient in the morning (*Med. Times*, April 19, p. 539).

At a very influential meeting at the Parkes Museum on March 27 last, at which Dr. Watson Cheyne gave a demonstration of pathogenic micro-organisms, the Chairman, Sir Joseph Lister, remarked that the interesting fact that the bacillus of septicæmia of the house mouse was not capable of causing the disease in the field mouse, led him to conceive that if the slight difference in the blood of these two animals was sufficient to alter the conditions favourable to the development of the bacteria, it was possible by the administration of some medicines that sufficient alteration might be produced in the blood of the human system to kill off or prevent the development of any special bacteria on the first appearance of the symptoms of the disease in the patient.

An examination of the bacteria found in the human intestines has been made by T. Bienstock. He found that in healthy men these belonged exclusively to the group *Bacillus*, their spores alone having sufficient power of resistance to the antiseptic action of the gastric fluid. Of this group five distinct forms were observed, but of these only two manifested any remarkable chemical or physiological properties. These two are invariably present in the digestive canal below the stomach in individuals beyond the age of suckling. The one form causes the decomposition of albumen: this was absent in the intestines of infants fed only on milk. The other has only the power of splitting up carbohydrates, from which it forms alcohol and lactic acid. After cultivation for from twenty to sixty generations these bacilli still retain their power. (*Journ. Microsc. Soc.*, p. 267).

According to some experiments made by G. Bufalini (*Brit. Med. Journ.*, March 29, p. 626) the poison of viperine differs from that of the colubrine snake in resembling the action of an alkaloid, inasmuch as the blood of animals poisoned with viperine poison is not capable of causing death when injected into another animal, whereas that of animals poisoned by the colubrine snake can do so. The difficulty of finding a general antidote for snake bite is thus increased, since it is obvious that what may be an antidote in one case is not likely to be so in another.

In an article in the *American Journal of Pharmacy* (p. 188), translated from the *Pharmaceutische Rundschau*, on "Pipitzahoic Acid," Dr. Charles Mohr gives two figures of species of *Perezia*, whose roots yield this beautiful substance, and states that *Perezia Wrightii*, Gr., yields larger quautities of the acid than *P. nana*, Gr.

Some investigations made by Kugler on the suberin of the *Quercus Suber* indicate that it has a relationship with the fatty oils. He regards it as a fatty oil, composed chiefly of stearine and the glycerine compound of a new acid, phellonic acid, $C_{20}H_{42}O_3$, which has a melting point of 96° C. This throws some light on the formation of Japanese wax in the epidermis of the fruits of *Rhus succedanea*, and of Carnauba wax on the leaves of *Corypha cerifera*, which appear to result from the suberization of the cell walls.

In the *Journal of Botany* (April, p. 124) Mr. Greenwood Price points out that crystals of the colouring material present in the petals and other parts of plants are not, as a rule, easy to obtain, but that they can be easily seen in the well-known stove plant *Justicia speciosa*. If a fragment of a stamen of this flower be mounted in dilute glycerine jelly, not too hot, the colouring matter collects in a few hours in the form of minute, slender prisms, forming a very interesting microscopical object under a quarter-inch objective.

From some researches made by H. Pick it would appear that the red colouring matter of the young shoots and leaves of trees and perennial plants, such as the oak, rose, willow, and cinnamon, is always connected with the presence of tannin, at the expense of which it is formed under the influence of the direct action of sunlight and a low temperature. By the experiment of growing plants behind a screen of the solution of this red colouring matter it was ascertained that the red light is especially favourable to the absorption and transport of starch. The bright red colour of the fruit of *Rivina humilis*, and the bracts of *Euphorbia fulgens*, is, however, according to T. Hildebrand, produced by the superposition of cells containing different pigments of orange and violet-red, and the colouring matter of the bright red root of *Wachendorffia thyrsiflora* is due to a coloured fluid substance in the cells, which is formed even in absolute darkness.

The gourd, *Cucurbita Pepo*, contains large sieve-tubes, from which, when wounded, a juice flows out in large quantities, of an alkaline reaction, which can easily be separated from the ordinary cell-sap. The composition of this juice has been investigated by E. Zacharias by ordinary chemical tests. He finds three classes of substances in the juice:—albuminoids, non-albuminous organic substances, and inorganic salts. If the juice from the sieve-tubes is allowed to stand for a short time, the albuminoids readily separate from it in the form of a transparent colourless rather stiff jelly. Chemical tests show that this substance is of the nature of fibrine, mixed with a small quantity of a substance insoluble in the gastric juice and in dilute potash ley. When this has been removed by strong alcohol, a substance is left in the filtrate which turns the plane of polarization to the right. This substance is of the nature of dextrin, and is converted by dilute sulphuric acid into glucose. The presence of a nitrate or nitrite can also be recognized both in the aqueous solution and in the ash. Zacharias was unable altogether to decide the question of the presence or absence of amido-acids and of other organic nitrogenous compounds soluble in water. Of inorganic salts there was found in the ash distinct evidence of the presence of magnesia. Experiments also indicated the probable presence in the sieve-tubes of potassium phosphate, to which may be attributed the alkaline reaction of the juice.

In *Nature* (April 10, p. 552), Mr. Marshall Ward gives an interesting extract from the *Arbeiten des botanisches Institut*, of Wurtemberg, of work done by Professor Sachs during last year, relating to the formation and disappearance of starch in plants in the open air. It appears from Sachs' observations that the starch formed in the leaves during the day may disappear completely during the night, and that the leaves shown to be full of starch in the evening may be quite free from it the next morning. This he proved by cutting a leaf longitudinally in half on a fine sunny day, placing the one half in boiling water for about ten minutes, then in alcohol to remove chlorophyll, etc., and then laying the decolorized leaf in an alcoholic solution of iodine, the other half of the leaf being similarly tested the next morning before sunrise. He has also confirmed the statement that the transformation of the starch into glucose and the transference of the latter by way of vascular bundles into the stems also goes on during daylight, but is less evident because more starch is formed than is abstracted. This fact had already been demonstrated by Moll, by exposing leaves to the sunlight in an atmosphere freed from carbonic acid by potassic hydrate. The average amount of starch produced per square metre is estimated by Sachs to be 20 to 25 grams per day, and the average rate of production at 1·648 grams per hour. Mr. Ward points out that several practical results follow from these experiments. Leaves used as fodder, hay, etc., will vary very much in nutritive value, according to the warmth and brightness, etc., of the weather, and the time of day when it is cut, and the same remark applies to the collection of tobacco, tea, etc., the former of which, in some countries, is habitually cropped in the morning. It may be added also that the knowledge thus arrived at may be turned to account in the collection of medicinal plants for the preparation of extracts.

At the meeting of the Linnean Society on April 3, Mr. W. Brockbank exhibited a series of double daffodils, some of which showed that the double character of the flower was not due to the alteration of the stamen nor to the multiplication of the floral envelopes at the expense of the ovules, inasmuch as in some specimens of double flowers stamens were present, and in others the ovary was full of ovules. He believed that the double flowering plants were propagated by seed.

Some interesting experiments have been carried out by F. Heyer (*Journ. Microsc. Soc.*, p. 251) with a view to determine the cause of differentiation of sex in unisexual plants. The results obtained in the case of diœcious plants, by experiments with twenty-one thousand specimens of *Mercurialis annua* and six thousand of *Cannabis indica*, was that external conditions have no influence on the production of seedlings of one or the other sex. In the case of the former plant the proportion of males to females produced was as 105·85 to 100, and in the latter as 86 to 100. In a second series of experiments made with monœcious plants to determine whether external conditions of temperature and soil caused any difference in the proportion of male and female flowers, *Urtica urens*, *Atriplex Spinacia*, *Xanthium*, and various *Cucurbitaceæ* produced negative results. He also came to the conclusion that sex is determined at an earlier period than the ripening of the seed. A knowledge of the means whereby female plants could be produced at will would be of considerable commercial importance, as, for instance, in the cultivation of nutmegs.

J. Constantin finds as the results of extended investigations that the duration of a plant and the presence of a rhizome or other underground stem are, to a certain extent, dependent on external circumstances. Thus the proportion of perennial plants increases with the altitude above the sea level, and the same species is sometimes annual at low altitudes and perennial at high elevations. The tissues of the stem become modified by being buried in the soil. The angles of the aerial stem when present tend to disappear, a suberous layer or a suberized epidermis being much developed; the means of support, such as collenchyma, liber fibres, etc., tend to disappear, and food materials are largely increased (*Journ. Microsc. Soc.*, p. 253).

At a recent meeting of the Linnean Society the Rev. J. M. Crombie read a paper controverting the Schwendenerian theory of the composite algal-fungal nature of lichens. In support of his position he pointed out that the hyphæ of lichens differ from those of fungi in being straighter, much more permanent in character than those of fungi, in containing lichenin, and in not being destroyed by solution of potash. He showed also that in cases where the hyphæ of fungi penetrate lichens on trees or rocks they invariably destroy the gonidia, instead of stimulating their growth, and that the same takes place when algæ on the bark of trees are attacked by fungal mycelium. Some very pretty specimens of lichens in an early stage of growth on bare flints and pebbles were exhibited, showing the hypothallus with the lichen thallus just forming under circumstances in which algæ would not flourish.

Some important facts have been ascertained concerning the development of bark, which may probably throw some light upon the best mode of cultivating cinchona trees for the bark. A. Gehmacher finds that the growth of bark is influenced greatly by pressure, that the less the pressure the more numerous the cork cells become, and the greater the pressure the more they diminish. The bast fibres also increase considerably in number with diminution of pressure; when the pressure is very great very few bast fibres or none at all are formed. The bast fibres also increase in size with diminished pressure.

Apropos of what has been remarked concerning the value of cinchona barks, Dr. de Vrij writes that at Amsterdam on February 29 last he observed that two lots of Ledgeriana bark containing 4·05 per cent. of pure quinine were sold at 3*s*. 7*d*. per half kilogramme, whilst one lot of red bark containing 7·35 per cent. of total alkaloids and only 1·18 per cent. of pure quinine was sold at 3*s.* 5*d.* per half kilogramme. The latter was, however, in long quills having a fine appearance. It is obvious, therefore, that price alone is no indication of alkaloidal contents. He also remarks that the presence of cinchonidine in many samples of commercial quinine is easily detected by the optical test recommended a few years ago by Professor A. C. Oudemans.

When balsam of peru arrives at Acajutla and La Libertad, the ports on the "balsam coast" from which it is chiefly shipped, it is in a crude state, usually of a grey-green to a dirty yellow colour, and requires to be submitted to a process of purification before it is fit for exportation. Concerning this process a correspondent of Messrs. Gehe and Co. furnishes some interesting information. He states that a first clarification is effected by allowing the crude balsam to stand in a large iron vessel capable of holding six or seven hundred pounds during a week or a fortnight, by which time the heavier impurities sink to the bottom and the lighter ones float as a scum on the surface. The clear balsam, which has already attained its characteristic black-brown colour, is then drawn off through a tap fixed about four inches from the bottom of the vessel and run into a tinned iron boiler set over an open fire and boiled moderately for two or three hours. All scum is removed as it makes its appearance, and the boiling is continued as long as any continues to be formed. It can easily be understood that the physical properties of the balsam will differ according to the temperature to which it is submitted during this boiling, and it is alleged that the lower specific gravity observed in balsam of peru during recent years is attributable to a modification it undergoes in this operation, and is quite consistent with the genuineness of a given sample.

Besides the foregoing the new quarterly report of Messrs. Gehe has several interesting notes. It is mentioned that whilst a few years since the price of quinidine (conquinine) was double that of cinchonidine, cinchonidine has lately found so much favour in the United States that its price has now become relatively higher than that of quinidine. This tendency has been favoured by the large quantities of cuprea bark that have been worked during the last few years, since in it quinine is accompanied only by quinidine and by no cinchonidine. In Germany the consumption of codeine has become so large that orders have to be executed in the order in which they are received and a hope is expressed that its preparation synthetically upon the manufacturing scale may become possible. Further, the demand for the glucoside adonidin, which is said to resemble digitalin in its action on the heart without being cumulative, has been so extensive that all the native grown *Adonis vernalis* was bought up immediately after gathering, and it became necessary to look to Southern Russia for a further supply of the herb. A tincture from the flowers and leaves of *Convallaria majalis* also remains in request as a digitalis substitute, but digitalin, notwithstanding its competitors, still holds its place. Arbutin, the glycoside obtained from the leaves of *Arbutus uva-ursi* is being used for diseases of the kidneys and bladder. As anæsthetics the bromide and chloride of ethylene are stated to be again coming into favour for external use, and to these the iodide has recently been added. The two former are liquids, but the iodide is a white crystalline substance. Bromide of ethyl is also in active request for internal administration.

THE USE OF ROSOLIC ACID AS AN INDICATOR, WITH ADDITIONAL NOTES ON PHENOLPHTHALEIN AND METHYL ORANGE.*

BY ROBERT T. THOMSON.

The following notes are simply an addition to my former paper on the use of litmus, methyl orange, phenacetolin and phenolphthalein as indicators. The object in view, as I stated before, was to determine the value of each indicator when applied to the estimation of alkalies and free acids, and to ascertain the effect (if any) of the impurities, such as sulphites, sulphides, phosphates, etc., usually found in commercial hydrates and carbonates of the alkalies. The tests were carried out in precisely the same way as described in the former part of this paper.

(1) *Delicacy of Rosolic Acid in Absence of Interfering Agents.*—The solution employed contained 2 grams of rosolic acid per litre, 50 per cent. alcohol being the solvent used. To test the delicacy of this indicator ·5 c.c. of its solution was added to 100 c.c. of distilled water and decinormal hydrate of sodium (1 c.c. = ·0031 gram Na_2O) dropped in. To effect the complete transformation of the pale yellow to a deep pink colour only ·1 c.c. of the standard alkali was required. This is equal to ·01 c.c. of normal alkali, and this figure should be borne in mind for the sake of comparing the delicacy of the rosolic acid in absence of interfering agents with its delicacy in presence of the salts to be examined.

(2) *Application of Rosolic Acid to the Determination of Available Alkali in Pure Hydrate, Carbonate and Bicarbonate of Sodium and Potassium.*—It is hardly necessary to give a detailed account of this portion of the subject. Several tests were made with quantities of the hydrate and carbonate of sodium and potassium containing 1·55 grams of Na_2O and 2·355 grams of K_2O respectively, with the result that exactly these amounts were obtained in each case by titration with normal sulphuric acid. The deep pink colour retains its original intensity up to the point at which bicarbonate of sodium is produced, but soon gives place to pale yellow, owing to the action of the liberated carbonic acid. It is therefore necessary to boil the solution thoroughly after each addition of acid to bring back the pink colour, and when this is attended to the end-reaction is extremely delicate, and can be effected by at least one drop (about ·05 c.c.) of normal acid.

(3) *Determination of Free Ammonia.*—Several experiments made in each case with a solution containing ·85 gram of ammonia (NH_3) gave identical and accurate results. The pink colour remained undiminished in intensity until 49·8 c.c. of the normal acid had been consumed; but on further addition of acid drop by drop, the pink slowly acquired a yellow tinge, and when 50 c.c. had been added the former was wholly eliminated, leaving only the pale yellow colour; but although this is the case, the end-reaction is tolerably distinct. This decrease in delicacy of the rosolic acid is not due to carbonic acid, as the ammonia employed did not contain an appreciable quantity of carbonate; but, as I shall show presently, is owing to the action of the salt of ammonium formed. Rosolic acid has been specially recommended as an indicator for ammonia determinations, but it is evident that it has no peculiar value for that purpose, even the much-abused litmus being considerably superior to it.

(4) *Effect of Sulphate, Chloride, and Nitrate of Sodium, Potassium, and Ammonium.*—The quantities of these salts operated upon were equivalent to 1·55 gram of soda (Na_2O), 2·355 grams of potash (K_2O), and ·85 gram of ammonia (NH_3) respectively. The presence of these salts of sodium and potassium does not sensibly affect the delicacy of the rosolic acid, but each of the salts of

* Read before the Chemical Section of the Philosophical Society of Glasgow, March 19, 1883. Reprinted from the *Proceedings of the Philosophical Society of Glasgow.*

ammonium required ·2 c.c. of normal hydrate of sodium to develop fully the deep pink colour, as against ·01 c.c. when tested with distilled water alone.

(5) *Effect of Sulphite of Sodium.*—The remainder of the experiments were made only on sodium salts, as I did not think it necessary to examine further the potassium and ammonium salts. Two tests were made with 3·15 grams of normal sulphite of sodium, which contain 1·55 grams of soda (Na_2O). When titrated in the cold only ·2 c.c. of normal sulphuric acid was required in both cases to destroy the pink colour, but, when boiled, 5 and 5·2 c.c. were respectively necessary, the results being, in the cold ·006, and in the hot ·155 and ·161 gram of soda (Na_2O). On cooling the boiled solution and titrating back with normal soda, 4·8 c.c. were required to restore the pink colour. From these results it is evident that normal sulphite of sodium (Na_2SO_3) is practically neutral to rosolic acid in the cold, which it also is, as I showed before, to phenolphthalein, while to methyl orange, litmus, and phenaceto in the bisulphite ($NaHSO_3$) is the neutral salt. It is noteworthy that the two last-named indicators give, with the sulphite, very undecided end-reactions, while the three former give very sharp and well-defined end-reactions.

(6) *Effect of Thiosulphate of Sodium.*—This salt is perfectly neutral to rosolic acid.

(7) *Effect of Sulphide of Sodium.*—The whole of the sodium in this compound is accurately estimated by standard sulphuric acid, with rosolic acid as indicator. The pink colour retained its original intensity until the sodium hydrogen sulphide (NaHS) was formed, but on further addition of acid gave place to yellow, owing to the action of the liberated sulphuretted hydrogen. On boiling, the pink colour returned, and a very sharp end-reaction was secured. It is only necessary to state that the results agreed substantially with those obtained with methyl orange and litmus.

(8) *Effect of Phosphate of Sodium.*—Two tests were made with 1·775 grams of monoacid orthophosphate of sodium, which contains ·775 gram of soda (Na_2O). In one case 12, and in the other 12·2 c.c. of normal acid were necessary to complete the change from deep pink to yellow. As the transformation in colour was gradual, the end-reaction was extremely unsatisfactory. The results, however, show that the monoacid sodium phosphate is strongly alkaline, and the diacid salt practically neutral to rosolic acid. It is noteworthy that rosolic acid agrees in this respect with litmus, methyl orange, and phenacetolin, but differs from phenolphthalein, which indicates the monoacid phosphate as the neutral salt; while normal sodium sulphite is neutral to both rosolic acid and phenolphthalein, but strongly alkaline to litmus, methyl orange, and phenacetolin.

(9) *Effect of Silicate of Sodium.*—With rosolic acid as indicator, the whole of the soda can be estimated by titration with standard sulphuric acid. This must be done in a boiling solution, as otherwise a good end-reaction is not obtainable. The tests were made side by side with experiments made on the same quantity of silicate of sodium and using methyl orange as indicator. The results were identical.

(10) *Effect of Alumina.*—The solution employed for each experiment contained ·775 gram of available soda, and ·103 gram of alumina. In one titration 25·2 c.c., and in the other 25·25 c.c. of normal sulphuric acid were consumed, which show ·781 and ·782 gram of soda respectively, instead of ·775. Rosolic acid thus behaves in much the same way, and gives high results to the same extent, as litmus.

(11) *Effect of Nitrite of Sodium.*—This salt is quite neutral to rosolic acid.

(12) *Determination of Soda in Borax.*—Rosolic acid is not well fitted for use in this titration, as the end-reaction is extremely indistinct. A solution containing 1·683 grams of biborate of sodium ($Na_2B_4O_7$), which is equal to ·516 gram of soda, was employed; but after the addition of 13·6 c.c. of normal sulphur acid, its pink began to assume a yellow tint, and the former colour was not discharged till 16·6 c.c. had been consumed. This latter result gives ·514 gram of soda as against ·516 actually present. I showed before that the best indicator for borax was methyl orange, which gives a well-defined end-reaction.

(13) *Determination of Free Sulphuric, Nitric, Hydrochloric, and Oxalic Acids.*—Rosolic acid is an excellent indicator for use in the determination of these free acids, either by standard hydrate of sodium or potassium, the end-reaction being extremely delicate.

(14) *Determination of Free Tartaric Acid.*—For this purpose rosolic acid is not so well fitted as phenolphthaline; but the end-reaction is tolerably distinct, and fairly accurate results are obtainable.

(15) *Determination of Free Acetic and Citric Acids.*—Rosolic acid is useless as an indicator in the determination of these acids, as, besides the end-reactions being very indefinite, normal acetate of sodium is slightly, and normal citrate of sodium considerably alkaline to this indicator. In this respect rosolic acid resembles litmus, while the delicacy of phenolphthalein, and the accuracy of the determinations made with it, are perfect.

It is plainly evident, on taking a survey of the above results, that rosolic acid has no particular superiority over other indicators, unless in some cases the fact of normal sulphite of sodium being neutral to it in cold solutions may be found useful. In nearly every case it behaves like litmus, and has none of the good qualities not possessed by the latter indicator, but which distinguish phenolphthalein, methyl orange and phenacetolin.

Having now concluded the consideration of rosolic acid, I will give a few supplementary notes on the use of phenolphthalein and methyl orange as indicators.

(1) *Determination of Free Citric and Acetic Acids.*—In the former portion of this paper phenolphthalein was recommended as being the only perfect indioator for this purpose, but it was not mentioned that the titration should be done in the cold. The reason for this is, that although the normal citrate and acetate of sodium are quite neutral to phenolphthalein in the cold, yet when heated they give a slightly alkaline reaction (this is especially the case with the citrate), so that a sensibly high result would be obtained in a hot solution. Of course, in the case of acetic acid a hot solution dare not be used, unless excess of soda is first added, and titrated back with acid.

(2) *Phenolphthalein as an Indicator in the Determination of Free Ammonia.*—This is a very important point to which special attention should be directed, particularly with the view of correcting some misleading statements that have been published respecting this indicator. I pointed out formerly that phenolphthalein was incapable of showing at what point a solution containing a salt of ammonia was neutral, the reason being that such a salt had the effect of destroying the red colour produced by the ammonia, even when the latter was present in considerable proportion. Phenolphthalein has, however, been directly recommended as an indicator for ammonia by one author, and the monoacid phosphates of sodium, potassium and ammonium have been stated by another chemist to be neutral to it. This is true as regards the phosphates of sodium and potassium, but with the ammonium salt no definite neutral point is obtainable, owing to the decolorizing action of the salt itself. The experiments made by these chemists have evidently been confined to potassium and sodium salts, while the behaviour of the ammonium salts has been simply assumed from these results. These facts show how incorrect statements may be made by trusting solely to the analogy between the salts of the alkali metals and ammonium.

(3) *Valuation of Phosphate of Sodium or Potassium and Phosphoric Acid.*—In the former portion of this paper I

had occasion to describe the behaviour of normal orthophosphate of sodium and potassium when titrated with sulphuric acid, methyl orange and phenolphthalein being used respectively as indicators. The neutral point with methyl orange is reached when the diacid phosphate (NaH_2PO_4 or KH_2PO_4) is formed, while with phenolphthalein the neutral salt is the monoacid phosphate (Na_2HPO_4 or K_2HPO_4). On this definite difference of indication (which represents exactly one-third of the phosphoric acid present) I have ventured to base a process, which gives fairly accurate results, for the valuation of any of the orthophosphates of sodium or potassium, or of phosphoric acid. This is certainly a determination that is seldom required, but a rapid process of this description is at least of some interest, and may occasionally be found useful. The method consists in adding to 5 or 10 grams of the sample, previously dissolved in about 80 c.c. of water, normal sulphuric acid from a burette till the faintly acid reaction with methyl orange is obtained, or, in the case of phosphoric acid, normal caustic soda is added to the same point. The amount of acid or alkali added need not be measured, as the object is simply to add exactly enough to produce the diacid phosphate. The mixture is now boiled for a short time to expel carbonic acid, if present; then cooled (if the solution is kept hot a low result will be the consequence), a little phenolphthalein added, and the titration accomplished by normal caustic soda or potash, one c c. of which will represent ·098 gram of phosphoric acid (H_3PO_4), or ·142 gram of monoacid sodium phosphate (Na_2HPO_4). Several tests were made of a sample of ordinary phosphate of soda, the results being controlled by two determinations by precipitation with magnesia mixture. The following were the results:—

By Alkalimetric Method.			By Precipitation as $Mg_2P_2O_7$.
Grams of Phosphate of Soda tested.	C.c. of normal NaHO consumed.	Percentage of Na_2HPO_4.	Percentage of Na_2HPO_4.
10	28·1	39·90	40·29
5	14·1	40·04	40·35
5	14·1	40·04	—

The theoretical percentage of dry phosphate of sodium in the crystallized compound is 39·66. It will be readily seen, from the nature of the process, that the presence of carbonate, sulphate, chloride, nitrate, thiosulphate or sulphide of sodium or potassium, will not influence the accuracy of the results. If sulphite of sodium is present, it must first be oxidized to sulphate by the addition of a little peroxide of hydrogen (excess of which does not affect the delicacy of the indicators), as otherwise a high result would be obtained.

It will be observed that I have not noticed the application of phenolphthalein as an indicator in the determination of caustic alkali in soaps, of free and combined fatty acids in oils and fats, and of resin acids—the reason being that this subject has been fully entered into by various chemists.

In conclusion, I may state that I am examining further the behaviour of phenolphthalein, methyl orange, phenacetolin, rosolic acid, litmus and other indicators, with other chemical compounds, having in view the special object of extending their employment, if possible, in the analysis of commercial chemical products.

NIGELLA SATIVA.*

BY HENRY G. GREENISH.
